 & & \downarrow & \swarrow & \downarrow \\
 (X, x) & \longleftarrow & (Z_1, z_1) & \longleftarrow & (S'', s'') & \longleftarrow & (Y''_1, y''_1) \\
 \downarrow & & \downarrow & \swarrow & \downarrow & \swarrow & \\
 (S, s) & \longleftarrow & (Y_1, y_1) & & & &
 \end{array}$$

with all the properties as listed in the referenced lemma. In particular $Y''_1 \subset Y'_1 \times_{S'} S''$. Set $X_1 = Y'_1 \times_{S'} S''$ and let \mathcal{F}_1 denote the pullback of $\text{Coker}(\alpha_1)$. By Lemma 37.5.4 the system

$$(37.5.7.2) \quad (Z_k \times_{S'} S'', Y_k \times_{S'} S'', i''_k, \pi''_k, \mathcal{G}''_k, \alpha''_k, z''_k, y''_k)_{k=2, \dots, n}$$

is a complete dévissage of \mathcal{F}_1 to X_1 . Again, the nature of the problem allows us to replace $(X, x) \rightarrow (S, s)$ by $(X'', x'') \rightarrow (S'', s'')$. In this we see that we may assume:

- (a) There exists a one step dévissage $(Z_1, Y_1, i_1, \pi_1, \mathcal{G}_1)$ of $\mathcal{F}/X/S$ at x ,
- (b) there exists an $\alpha_1 : \mathcal{O}_{Y_1}^{\oplus r_1} \rightarrow \pi_{1,*}\mathcal{G}_1$ such that $\alpha \otimes \kappa(\xi_1)$ is an isomorphism,
- (c) $Y_1 \subset X_1$ is open, $y_1 = x_1$, and $\mathcal{F}_1|_{Y_1} \cong \text{Coker}(\alpha_1)$, and
- (d) there exists a complete dévissage $(Z_k, Y_k, i_k, \pi_k, \mathcal{G}_k, \alpha_k, z_k, y_k)_{k=2, \dots, n}$ of $\mathcal{F}_1/X_1/S$ at x_1 .

To finish the proof all we have to do is shrink the one step dévissage and the complete dévissage such that they fit together to a complete dévissage. (We suggest the reader do this on their own using Lemmas 37.4.7 and 37.5.6 instead of reading the proof that follows.) Since $Y_1 \subset X_1$ is an open neighbourhood of x_1 we may apply Lemma 37.5.6 (3) to find a standard shrinking $S', X'_1, Z'_2, Y'_2, \dots, Y'_n$ of the datum (d) so that $X'_1 \subset Y_1$. Note that X'_1 is also a standard open of the affine scheme Y_1 . Next, we shrink the datum (a) as follows: first we shrink the base S to S' , see Lemma 37.4.7 (1) and then we shrink the result to S'', X'', Z''_1, Y''_1 using Lemma 37.4.7 (2) such that eventually $Y''_1 = X'_1 \times_S S''$ and $S'' \subset S'$. Then we see that

$$Z''_1, Y''_1, Z'_2 \times_{S'} S'', Y'_2 \times_{S'} S'', \dots, Y'_n \times_{S'} S''$$

gives the complete dévissage we were looking for. □

Some more bookkeeping gives the following consequence.

Lemma 37.5.8. *Let $X \rightarrow S$ be a finite type morphism of schemes. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Let $s \in S$ be a point. There exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and étale morphisms $h_i : Y_i \rightarrow X_{S'}$, $i = 1, \dots, n$ such that for each i there exists a complete dévissage of $\mathcal{F}_i/Y_i/S'$ over s' , where \mathcal{F}_i is the pullback of \mathcal{F} to Y_i and such that $X_s = (X_{S'})_{s'} \subset \bigcup h_i(Y_i)$.*

Proof. For every point $x \in X_s$ we can find a diagram

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (S', s') \end{array}$$

of pointed schemes such that the horizontal arrows are elementary étale neighbourhoods and such that $g^*\mathcal{F}/X'/S'$ has a complete dévissage at x' . As $X \rightarrow S$ is of finite type the fibre X_s is quasi-compact, and since each $g : X' \rightarrow X$ as above is open we can cover X_s by a finite union of $g(X'_s)$. Thus we can find a finite family of such diagrams

$$\begin{array}{ccc} (X, x) & \xleftarrow{g_i} & (X'_i, x'_i) \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (S'_i, s'_i) \end{array} \quad i = 1, \dots, n$$

such that $X_s = \bigcup g_i(X'_i)$. Set $S' = S'_1 \times_S \dots \times_S S'_n$ and let $Y_i = X_i \times_{S'_i} S'$ be the base change of X'_i to S' . By Lemma 37.5.3 we see that the pullback of \mathcal{F} to Y_i has a complete dévissage over s and we win. \square

37.6. Translation into algebra

It may be useful to spell out algebraically what it means to have a complete dévissage. We introduce the following notion (which is not that useful so we give it an impossibly long name).

Definition 37.6.1. Let $R \rightarrow S$ be a ring map. Let \mathfrak{q} be a prime of S lying over the prime \mathfrak{p} of R . A *elementary étale localization of the ring map $R \rightarrow S$ at \mathfrak{q}* is given by a commutative diagram of rings and accompanying primes

$$\begin{array}{ccc} S & \longrightarrow & S' \\ \uparrow & & \uparrow \\ R & \longrightarrow & R' \end{array} \quad \begin{array}{ccc} \mathfrak{q} & \longrightarrow & \mathfrak{q}' \\ \downarrow & & \downarrow \\ \mathfrak{p} & \longrightarrow & \mathfrak{p}' \end{array}$$

such that $R \rightarrow R'$ and $S \rightarrow S'$ are étale ring maps and $\kappa(\mathfrak{p}) = \kappa(\mathfrak{p}')$ and $\kappa(\mathfrak{q}) = \kappa(\mathfrak{q}')$.

Definition 37.6.2. Let $R \rightarrow S$ be a finite type ring map. Let \mathfrak{r} be a prime of R . Let N be a finite S -module. A *complete dévissage of $N/S/R$ over \mathfrak{r}* is given by R -algebra maps

$$\begin{array}{ccccccc} & & A_1 & & A_2 & & \dots & & A_n \\ & \nearrow & & \nwarrow & \nearrow & \nwarrow & \nearrow & \nwarrow & \nearrow \\ S & & & & B_1 & & \dots & & B_n \end{array}$$

finite A_i -modules M_i and B_i -module maps $\alpha_i : B_i^{\oplus r_i} \rightarrow M_i$ such that

- (1) $S \rightarrow A_1$ is surjective and of finite presentation,
- (2) $B_i \rightarrow A_{i+1}$ is surjective and of finite presentation,
- (3) $B_i \rightarrow A_i$ is finite,
- (4) $R \rightarrow B_i$ is smooth with geometrically irreducible fibres,

- (5) $N \cong M_1$ as S -modules,
- (6) $\text{Coker}(\alpha_i) \cong M_{i+1}$ as B_i -modules,
- (7) $\alpha_i : \kappa(\mathfrak{p}_i)^{\oplus r_i} \rightarrow M_i \otimes_{B_i} \kappa(\mathfrak{p}_i)$ is an isomorphism where $\mathfrak{p}_i = \mathfrak{r}B_i$, and
- (8) $\text{Coker}(\alpha_n) = 0$.

In this situation we say that $(A_i, B_i, M_i, \alpha_i)_{i=1, \dots, n}$ is a complete dévissage of $N/S/R$ over \mathfrak{r} .

Remark 37.6.3. Note that the R -algebras B_i for all i and A_i for $i \geq 2$ are of finite presentation over R . If S is of finite presentation over R , then it is also the case that A_1 is of finite presentation over R . In this case all the ring maps in the complete dévissage are of finite presentation. See Algebra, Lemma 10.6.2. Still assuming S of finite presentation over R the following are equivalent

- (1) M is of finite presentation over S ,
- (2) M_1 is of finite presentation over A_1 ,
- (3) M_1 is of finite presentation over B_1 ,
- (4) each M_i is of finite presentation both as an A_i -module and as a B_i -module.

The equivalences (1) \Leftrightarrow (2) and (2) \Leftrightarrow (3) follow from Algebra, Lemma 10.7.4. If M_1 is finitely presented, so is $\text{Coker}(\alpha_1)$ (see Algebra, Lemma 10.5.3) and hence M_2 , etc.

Definition 37.6.4. Let $R \rightarrow S$ be a finite type ring map. Let \mathfrak{q} be a prime of S lying over the prime \mathfrak{r} of R . Let N be a finite S -module. A *complete dévissage of $N/S/R$ at \mathfrak{q}* is given by a complete dévissage $(A_i, B_i, M_i, \alpha_i)_{i=1, \dots, n}$ of $N/S/R$ over \mathfrak{r} and prime ideals $\mathfrak{q}_i \subset B_i$ lying over \mathfrak{r} such that

- (1) $\kappa(\mathfrak{r}) \subset \kappa(\mathfrak{q}_i)$ is purely transcendental,
- (2) there is a unique prime $\mathfrak{q}'_i \subset A_i$ lying over $\mathfrak{q}_i \subset B_i$,
- (3) $\mathfrak{q} = \mathfrak{q}'_1 \cap S$ and $\mathfrak{q}_i = \mathfrak{q}'_{i+1} \cap A_i$,
- (4) $R \rightarrow B_i$ has relative dimension $\dim_{\mathfrak{q}_i}(\text{Supp}(M_i \otimes_R \kappa(\mathfrak{r})))$.

Remark 37.6.5. Let $A \rightarrow B$ be a finite type ring map and let N be a finite B -module. Let \mathfrak{q} be a prime of B lying over the prime \mathfrak{r} of A . Set $X = \text{Spec}(B)$, $S = \text{Spec}(A)$ and $\mathcal{F} = \tilde{N}$ on X . Let x be the point corresponding to \mathfrak{q} and let $s \in S$ be the point corresponding to \mathfrak{p} . Then

- (1) if there exists a complete dévissage of $\mathcal{F}/X/S$ over s then there exists a complete dévissage of $N/B/A$ over \mathfrak{p} , and
- (2) there exists a complete dévissage of $\mathcal{F}/X/S$ at x if and only if there exists a complete dévissage of $N/B/A$ at \mathfrak{q} .

There is just a small twist in that we omitted the condition on the relative dimension in the formulation of “a complete dévissage of $N/B/A$ over \mathfrak{p} ” which is why the implication in (1) only goes in one direction. The notion of a complete dévissage at \mathfrak{q} does have this condition built in. In any case we will only use that existence for $\mathcal{F}/X/S$ implies the existence for $N/B/A$.

Lemma 37.6.6. *Let $R \rightarrow S$ be a finite type ring map. Let M be a finite S -module. Let \mathfrak{q} be a prime ideal of S . There exists an elementary étale localization $R' \rightarrow S', \mathfrak{q}', \mathfrak{p}'$ of the ring map $R \rightarrow S$ at \mathfrak{q} such that there exists a complete dévissage of $(M \otimes_S S')/S'/R'$ at \mathfrak{q}' .*

Proof. This is a reformulation of Proposition 37.5.7 via Remark 37.6.5 □

37.7. Localization and universally injective maps

Lemma 37.7.1. *Let $R \rightarrow S$ be a ring map. Let N be a S -module. Assume*

- (1) *R is a local ring with maximal ideal \mathfrak{m} ,*
- (2) *$\bar{S} = S/\mathfrak{m}S$ is Noetherian, and*
- (3) *$\bar{N} = N/\mathfrak{m}_R N$ is a finite \bar{S} -module.*

Let $\Sigma \subset S$ be the multiplicative subset of elements which are not a zerodivisor on \bar{N} . Then $\Sigma^{-1}S$ is a semi-local ring whose spectrum consists of primes $\mathfrak{q} \subset S$ contained in an element of $\text{Ass}_S(\bar{N})$. Moreover, any maximal ideal of $\Sigma^{-1}S$ corresponds to an associated prime of \bar{N} over \bar{S} .

Proof. Note that $\text{Ass}_S(\bar{N}) = \text{Ass}_{\bar{S}}(\bar{N})$, see Algebra, Lemma 10.62.13. This is a finite set by Algebra, Lemma 10.62.5. Say $\{\mathfrak{q}_1, \dots, \mathfrak{q}_r\} = \text{Ass}_S(\bar{N})$. We have $\Sigma = S \setminus (\bigcup \mathfrak{q}_i)$ by Algebra, Lemma 10.62.9. By the description of $\text{Spec}(\Sigma^{-1}S)$ in Algebra, Lemma 10.16.5 and by Algebra, Lemma 10.14.2 we see that the primes of $\Sigma^{-1}S$ correspond to the primes of S contained in one of the \mathfrak{q}_i . Hence the maximal ideals of $\Sigma^{-1}S$ correspond one-to-one with the maximal (w.r.t. inclusion) elements of the set $\{\mathfrak{q}_1, \dots, \mathfrak{q}_r\}$. This proves the lemma. \square

Lemma 37.7.2. *Assumption and notation as in Lemma 37.7.1. Assume moreover that*

- (1) *S is local and $R \rightarrow S$ is a local homomorphism,*
- (2) *S is essentially of finite presentation over R ,*
- (3) *N is finitely presented over S , and*
- (4) *N is flat over R .*

Then each $s \in \Sigma$ defines a universally injective R -module map $s : N \rightarrow N$, and the map $N \rightarrow \Sigma^{-1}N$ is R -universally injective.

Proof. By Algebra, Lemma 10.124.4 the sequence $0 \rightarrow N \rightarrow N \rightarrow N/sN \rightarrow 0$ is exact and N/sN is flat over R . This implies that $s : N \rightarrow N$ is universally injective, see Algebra, Lemma 10.38.11. The map $N \rightarrow \Sigma^{-1}N$ is universally injective as the directed colimit of the maps $s : N \rightarrow N$. \square

Lemma 37.7.3. *Let $R \rightarrow S$ be a ring map. Let N be an S -module. Let $S \rightarrow S'$ be a ring map. Assume*

- (1) *$R \rightarrow S$ is a local homomorphism of local rings*
- (2) *S is essentially of finite presentation over R ,*
- (3) *N is of finite presentation over S ,*
- (4) *N is flat over R ,*
- (5) *$S \rightarrow S'$ is flat, and*
- (6) *the image of $\text{Spec}(S') \rightarrow \text{Spec}(S)$ contains all primes \mathfrak{q} of S lying over \mathfrak{m}_R such that \mathfrak{q} is an associated prime of $N/\mathfrak{m}_R N$.*

Then $N \rightarrow N \otimes_S S'$ is R -universally injective.

Proof. Set $N' = N \otimes_S S'$. Consider the commutative diagram

$$\begin{array}{ccc} N & \longrightarrow & N' \\ \downarrow & & \downarrow \\ \Sigma^{-1}N & \longrightarrow & \Sigma^{-1}N' \end{array}$$

where $\Sigma \subset S$ is the set of elements which are not a zerodivisor on $N/\mathfrak{m}_R N$. If we can show that the map $N \rightarrow \Sigma^{-1}N'$ is universally injective, then $N \rightarrow N'$ is too (see Algebra, Lemma 10.79.10).

By Lemma 37.7.1 the ring $\Sigma^{-1}S$ is a semi-local ring whose maximal ideals correspond to associated primes of $N/\mathfrak{m}_R N$. Hence the image of $\text{Spec}(\Sigma^{-1}S') \rightarrow \text{Spec}(\Sigma^{-1}S)$ contains all these maximal ideals by assumption. By Algebra, Lemma 10.38.15 the ring map $\Sigma^{-1}S \rightarrow \Sigma^{-1}S'$ is faithfully flat. Hence $\Sigma^{-1}N \rightarrow \Sigma^{-1}N'$, which is the map

$$N \otimes_S \Sigma^{-1}S \longrightarrow N \otimes_S \Sigma^{-1}S'$$

is universally injective, see Algebra, Lemmas 10.79.11 and 10.79.8. Finally, we apply Lemma 37.7.2 to see that $N \rightarrow \Sigma^{-1}N$ is universally injective. As the composition of universally injective module maps is universally injective (see Algebra, Lemma 10.79.9) we conclude that $N \rightarrow \Sigma^{-1}N'$ is universally injective and we win. \square

Lemma 37.7.4. *Let $R \rightarrow S$ be a ring map. Let N be an S -module. Let $S \rightarrow S'$ be a ring map. Assume*

- (1) $R \rightarrow S$ is of finite presentation and N is of finite presentation over S ,
- (2) N is flat over R ,
- (3) $S \rightarrow S'$ is flat, and
- (4) the image of $\text{Spec}(S') \rightarrow \text{Spec}(S)$ contains all primes \mathfrak{q} such that \mathfrak{q} is an associated prime of $N \otimes_R \kappa(\mathfrak{p})$ where \mathfrak{p} is the inverse image of \mathfrak{q} in R .

Then $N \rightarrow N \otimes_S S'$ is R -universally injective.

Proof. By Algebra, Lemma 10.79.12 it suffices to show that $N_{\mathfrak{q}} \rightarrow (N \otimes_S S')_{\mathfrak{q}}$ is a $R_{\mathfrak{p}}$ -universally injective for any prime \mathfrak{q} of S lying over \mathfrak{p} in R . Thus we may apply Lemma 37.7.3 to the ring maps $R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}} \rightarrow S'_{\mathfrak{q}}$ and the module $N_{\mathfrak{q}}$. \square

The reader may want to compare the following lemma to Algebra, Lemmas 10.95.1 and 10.124.4 and the results of Section 37.24. In each case the conclusion is that the map $u : M \rightarrow N$ is universally injective with flat cokernel.

Lemma 37.7.5. *Let (R, \mathfrak{m}) be a local ring. Let $u : M \rightarrow N$ be an R -module map. If M is a projective R -module, N is a flat R -module, and $\bar{u} : M/\mathfrak{m}M \rightarrow N/\mathfrak{m}N$ is injective then u is universally injective.*

Proof. By Algebra, Theorem 10.82.4 the module M is free. If we show the result holds for every finitely generated direct summand of M , then the lemma follows. Hence we may assume that M is finite free. Write $N = \text{colim}_i N_i$ as a directed colimit of finite free modules, see Algebra, Theorem 10.78.4. Note that $u : M \rightarrow N$ factors through N_i for some i (as M is finite free). Denote $u_i : M \rightarrow N_i$ the corresponding R -module map. As \bar{u} is injective we see that $\bar{u}_i : M/\mathfrak{m}M \rightarrow N_i/\mathfrak{m}N_i$ is injective and remains injective on composing with the maps $N_i/\mathfrak{m}N_i \rightarrow N_{i'}/\mathfrak{m}N_{i'}$ for all $i' \geq i$. As M and $N_{i'}$ are finite free over the local ring R this implies that $M \rightarrow N_{i'}$ is a split injection for all $i' \geq i$. Hence for any R -module Q we see that $M \otimes_R Q \rightarrow N_{i'} \otimes_R Q$ is injective for all $i' \geq i$. As $- \otimes_R Q$ commutes with colimits we conclude that $M \otimes_R Q \rightarrow N_{i'} \otimes_R Q$ is injective as desired. \square

Lemma 37.7.6. *Assumption and notation as in Lemma 37.7.1. Assume moreover that N is projective as an R -module. Then each $s \in \Sigma$ defines a universally injective R -module map $s : N \rightarrow N$, and the map $N \rightarrow \Sigma^{-1}N$ is R -universally injective.*

Proof. Pick $s \in \Sigma$. By Lemma 37.7.5 the map $s : N \rightarrow N$ is universally injective. The map $N \rightarrow \Sigma^{-1}N$ is universally injective as the directed colimit of the maps $s : N \rightarrow N$. \square

37.8. Completion and Mittag-Leffler modules

Lemma 37.8.1. *Let R be a ring. Let $I \subset R$ be an ideal. Let A be a set. Assume R is Noetherian and complete with respect to I . The completion $(\bigoplus_{\alpha \in A} R)^\wedge$ is flat and Mittag-Leffler.*

Proof. By More on Algebra, Lemma 15.19.1 the map $(\bigoplus_{\alpha \in A} R)^\wedge \rightarrow \prod_{\alpha \in A} R$ is universally injective. Thus, by Algebra, Lemmas 10.79.7 and 10.86.7 it suffices to show that $\prod_{\alpha \in A} R$ is flat and Mittag-Leffler. By Algebra, Proposition 10.87.5 (and Algebra, Lemma 10.87.4) we see that $\prod_{\alpha \in A} R$ is flat. Thus we conclude because a product of copies of R is Mittag-Leffler, see Algebra, Lemma 10.88.3. \square

Lemma 37.8.2. *Let R be a ring. Let $I \subset R$ be an ideal. Let M be an R -module. Assume*

- (1) R is Noetherian and I -adically complete,
- (2) M is flat over R , and
- (3) M/IM is a projective R/I -module.

Then the I -adic completion M^\wedge is a flat Mittag-Leffler R -module.

Proof. Choose a surjection $F \rightarrow M$ where F is a free R -module. By Algebra, Lemma 10.93.20 the module M^\wedge is a direct summand of the module F^\wedge . Hence it suffices to prove the lemma for F . In this case the lemma follows from Lemma 37.8.1. \square

In Lemmas 37.8.3 and 37.8.4 the assumption that S be Noetherian holds if $R \rightarrow S$ is of finite type, see Algebra, Lemma 10.30.1.

Lemma 37.8.3. *Let R be a ring. Let $I \subset R$ be an ideal. Let $R \rightarrow S$ be a ring map, and N an S -module. Assume*

- (1) R is a Noetherian ring,
- (2) S is a Noetherian ring,
- (3) N is a finite S -module, and
- (4) for any finite R -module Q , any $\mathfrak{q} \in \text{Ass}_S(Q \otimes_R N)$ satisfies $IS + \mathfrak{q} \neq S$.

Then the map $N \rightarrow N^\wedge$ of N into the I -adic completion of N is universally injective as a map of R -modules.

Proof. We have to show that for any finite R -module Q the map $Q \otimes_R N \rightarrow Q \otimes_R N^\wedge$ is injective, see Algebra, Theorem 10.79.3. As there is a canonical map $Q \otimes_R N^\wedge \rightarrow (Q \otimes_R N)^\wedge$ it suffices to prove that the canonical map $Q \otimes_R N \rightarrow (Q \otimes_R N)^\wedge$ is injective. Hence we may replace N by $Q \otimes_R N$ and it suffices to prove the injectivity for the map $N \rightarrow N^\wedge$.

Let $K = \text{Ker}(N \rightarrow N^\wedge)$. It suffices to show that $K_{\mathfrak{q}} = 0$ for $\mathfrak{q} \in \text{Ass}(N)$ as N is a submodule of $\prod_{\mathfrak{q} \in \text{Ass}(N)} N_{\mathfrak{q}}$, see Algebra, Lemma 10.62.18. Pick $\mathfrak{q} \in \text{Ass}(N)$. By the last assumption we see that there exists a prime $\mathfrak{q}' \supset IS + \mathfrak{q}$. Since $K_{\mathfrak{q}}$ is a localization of $K_{\mathfrak{q}'}$ it suffices to prove the vanishing of $K_{\mathfrak{q}'}$. Note that $K = \bigcap I^n N$, hence $K_{\mathfrak{q}'} \subset \bigcap I^n N_{\mathfrak{q}'}$. Hence $K_{\mathfrak{q}'} = 0$ by Algebra, Lemma 10.49.4. \square

Lemma 37.8.4. *Let R be a ring. Let $I \subset R$ be an ideal. Let $R \rightarrow S$ be a ring map, and N an S -module. Assume*

- (1) R is a Noetherian ring,
- (2) S is a Noetherian ring,
- (3) N is a finite S -module,
- (4) N is flat over R , and
- (5) for any prime $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R \kappa(\mathfrak{p})$ where $\mathfrak{p} = R \cap \mathfrak{q}$ we have $IS + \mathfrak{q} \neq S$.

Then the map $N \rightarrow N^\wedge$ of N into the I -adic completion of N is universally injective as a map of R -modules.

Proof. This follows from Lemma 37.8.3 because Algebra, Lemma 10.64.5 and Remark 10.64.6 guarantee that the set of associated primes of tensor products $N \otimes_R Q$ are contained in the set of associated primes of the modules $N \otimes_R \kappa(\mathfrak{p})$. \square

37.9. Projective modules

The following lemma can be used to prove projectivity by Noetherian induction on the base, see Lemma 37.9.2.

Lemma 37.9.1. *Let R be a ring. Let $I \subset R$ be an ideal. Let $R \rightarrow S$ be a ring map, and N an S -module. Assume*

- (1) R is Noetherian and I -adically complete,
- (2) $R \rightarrow S$ is of finite type,
- (3) N is a finite S -module,
- (4) N is flat over R ,
- (5) N/IN is projective as a R/I -module, and
- (6) for any prime $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R \kappa(\mathfrak{p})$ where $\mathfrak{p} = R \cap \mathfrak{q}$ we have $IS + \mathfrak{q} \neq S$.

Then N is projective as an R -module.

Proof. By Lemma 37.8.4 the map $N \rightarrow N^\wedge$ is universally injective. By Lemma 37.8.2 the module N^\wedge is Mittag-Leffler. By Algebra, Lemma 10.86.7 we conclude that N is Mittag-Leffler. Hence N is countably generated, flat and Mittag-Leffler as an R -module, whence projective by Algebra, Lemma 10.90.1. \square

Lemma 37.9.2. *Let R be a ring. Let $R \rightarrow S$ be a ring map. Assume*

- (1) R is Noetherian,
- (2) $R \rightarrow S$ is of finite type and flat, and
- (3) every fibre ring $S \otimes_R \kappa(\mathfrak{p})$ is geometrically integral over $\kappa(\mathfrak{p})$.

Then S is projective as an R -module.

Proof. Consider the set

$$\{I \subset R \mid S/IS \text{ not projective as } R/I\text{-module}\}$$

We have to show this set is empty. To get a contradiction assume it is nonempty. Then it contains a maximal element I . Let $J = \sqrt{I}$ be its radical. If $I \neq J$, then S/JS is projective as a R/J -module, and S/IS is flat over R/I and J/I is a nilpotent ideal in R/I . Applying Algebra, Lemma 10.74.5 we see that S/IS is a projective R/I -module, which is a contradiction. Hence we may assume that I is

a radical ideal. In other words we are reduced to proving the lemma in case R is a reduced ring and S/IS is a projective R/I -module for every nonzero ideal I of R .

Assume R is a reduced ring and S/IS is a projective R/I -module for every nonzero ideal I of R . By generic flatness, Algebra, Lemma 10.114.1 (applied to a localization R_g which is a domain) or the more general Algebra, Lemma 10.114.7 there exists a nonzero $f \in R$ such that S_f is free as an R_f -module. Denote $R^\wedge = \lim R/(f^n)$ the (f) -adic completion of R . Note that the ring map

$$R \longrightarrow R_f \times R^\wedge$$

is a faithfully flat ring map, see Algebra, Lemma 10.93.3. Hence by faithfully flat descent of projectivity, see Algebra, Theorem 10.92.5 it suffices to prove that $S \otimes_R R^\wedge$ is a projective R^\wedge -module. To see this we will use the criterion of Lemma 37.9.1. First of all, note that $S/fS = (S \otimes_R R^\wedge)/f(S \otimes_R R^\wedge)$ is a projective $R/(f)$ -module and that $S \otimes_R R^\wedge$ is flat and of finite type over R^\wedge as a base change of such. Next, suppose that \mathfrak{p}^\wedge is a prime ideal of R^\wedge . Let $\mathfrak{p} \subset R$ be the corresponding prime of R . As $R \rightarrow S$ has geometrically integral fibre rings, the same is true for the fibre rings of any base change. Hence $\mathfrak{q}^\wedge = \mathfrak{p}^\wedge(S \otimes_R R^\wedge)$, is a prime ideals lying over \mathfrak{p}^\wedge and it is the unique associated prime of $S \otimes_R \kappa(\mathfrak{p}^\wedge)$. Thus we win if $f(S \otimes_R R^\wedge) + \mathfrak{q}^\wedge \neq S \otimes_R R^\wedge$. This is true because $\mathfrak{p}^\wedge + fR^\wedge \neq R^\wedge$ as f lies in the radical of the f -adically complete ring R^\wedge and because $R^\wedge \rightarrow S \otimes_R R^\wedge$ is surjective on spectra as its fibres are nonempty (irreducible spaces are nonempty). \square

Lemma 37.9.3. *Let R be a ring. Let $R \rightarrow S$ be a ring map. Assume*

- (1) *$R \rightarrow S$ is of finite presentation and flat, and*
- (2) *every fibre ring $S \otimes_R \kappa(\mathfrak{p})$ is geometrically integral over $\kappa(\mathfrak{p})$.*

Then S is projective as an R -module.

Proof. We can find a cocartesian diagram of rings

$$\begin{array}{ccc} S_0 & \longrightarrow & S \\ \uparrow & & \uparrow \\ R_0 & \longrightarrow & R \end{array}$$

such that R_0 is of finite type over \mathbf{Z} , the map $R_0 \rightarrow S_0$ is of finite type and flat with geometrically integral fibres, see More on Morphisms, Lemmas 36.26.4, 36.26.6, 36.26.7, and 36.26.11. By Lemma 37.9.2 we see that S_0 is a projective R_0 -module. Hence $S = S_0 \otimes_{R_0} R$ is a projective R -module, see Algebra, Lemma 10.91.1. \square

Remark 37.9.4. Lemma 37.9.3 is a key step in the development of results in this chapter. The analogue of this lemma in [GR71] is [GR71, I Proposition 3.3.1]: If $R \rightarrow S$ is smooth with geometrically integral fibres, then S is projective as an R -module. This is a special case of Lemma 37.9.3, but as we will later improve on this lemma anyway, we do not gain much from having a stronger result at this point. We briefly sketch the proof of this as it is given in [GR71].

- (1) First reduce to the case where R is Noetherian as above.
- (2) Since projectivity descends through faithfully flat ring maps, see Algebra, Theorem 10.92.5 we may work locally in the fppf topology on R , hence

we may assume that $R \rightarrow S$ has a section $\sigma : S \rightarrow R$. (Just by the usual trick of base changing to S .) Set $I = \text{Ker}(S \rightarrow R)$.

- (3) Localizing a bit more on R we may assume that I/I^2 is a free R -module and that the completion S^\wedge of S with respect to I is isomorphic to $R[[t_1, \dots, t_n]]$, see Morphisms, Lemma 28.35.20. Here we are using that $R \rightarrow S$ is smooth.
- (4) To prove that S is projective as an R -module, it suffices to prove that S is flat, countably generated and Mittag-Leffler as an R -module, see Algebra, Lemma 10.90.1. The first two properties are evident. Thus it suffices to prove that S is Mittag-Leffler as an R -module. By Algebra, Lemma 10.88.4 the module $R[[t_1, \dots, t_n]]$ is Mittag-Leffler over R . Hence Algebra, Lemma 10.86.7 shows that it suffices to show that the $S \rightarrow S^\wedge$ is universally injective as a map of R -modules.
- (5) Apply Lemma 37.7.4 to see that $S \rightarrow S^\wedge$ is R -universally injective. Namely, as $R \rightarrow S$ has geometrically integral fibres, any associated point of any fibre ring is just the generic point of the fibre ring which is in the image of $\text{Spec}(S^\wedge) \rightarrow \text{Spec}(S)$.

There is an analogy between the proof as sketched just now, and the development of the arguments leading to the proof of Lemma 37.9.3. In both a completion plays an essential role, and both times the assumption of having geometrically integral fibres assures one that the map from S to the completion of S is R -universally injective.

37.10. Flat finite type modules, Part I

In some cases given a ring map $R \rightarrow S$ of finite presentation and a finite S -module N the flatness of N over R implies that N is of finite presentation. In this section we prove this is true “pointwise”. We remark that the first proof of Proposition 37.10.3 uses the geometric results of Section 37.3 but not the existence of a complete dévissage.

Lemma 37.10.1. *Let (R, \mathfrak{m}) be a local ring. Let $R \rightarrow S$ be a finitely presented flat ring map with geometrically integral fibres. Write $\mathfrak{p} = \mathfrak{m}S$. Let $\mathfrak{q} \subset S$ be a prime ideal lying over \mathfrak{m} . Let N be a finite S -module. There exist $r \geq 0$ and an S -module map*

$$\alpha : S^{\oplus r} \longrightarrow N$$

such that $\alpha : \kappa(\mathfrak{p})^{\oplus r} \rightarrow N \otimes_S \kappa(\mathfrak{p})$ is an isomorphism. For any such α the following are equivalent:

- (1) $N_{\mathfrak{q}}$ is R -flat,
- (2) α is R -universally injective and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat,
- (3) α is injective and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat,
- (4) $\alpha_{\mathfrak{p}}$ is an isomorphism and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat, and
- (5) $\alpha_{\mathfrak{q}}$ is injective and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat.

Proof. To obtain α set $r = \dim_{\kappa(\mathfrak{p})} N \otimes_S \kappa(\mathfrak{p})$ and pick $x_1, \dots, x_r \in N$ which form a basis of $N \otimes_S \kappa(\mathfrak{p})$. Define $\alpha(s_1, \dots, s_r) = \sum s_i x_i$. This proves the existence.

Fix an α . The most interesting implication is (1) \Rightarrow (2) which we prove first. Assume (1). Because $S/\mathfrak{m}S$ is a domain with fraction field $\kappa(\mathfrak{p})$ we see that $(S/\mathfrak{m}S)^{\oplus r} \rightarrow N_{\mathfrak{p}}/\mathfrak{m}N_{\mathfrak{p}} = N \otimes_S \kappa(\mathfrak{p})$ is injective. Hence by Lemmas 37.7.5 and

37.9.3. the map $S^{\oplus r} \rightarrow N_{\mathfrak{p}}$ is R -universally injective. It follows that $S^{\oplus r} \rightarrow N$ is R -universally injective, see Algebra, Lemma 10.79.10. Then also the localization $\alpha_{\mathfrak{q}}$ is R -universally injective, see Algebra, Lemma 10.79.13. We conclude that $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat by Algebra, Lemma 10.79.7.

The implication (2) \Rightarrow (3) is immediate. If (3) holds, then $\alpha_{\mathfrak{p}}$ is injective as a localization of an injective module map. By Nakayama’s lemma (Algebra, Lemma 10.19.1) $\alpha_{\mathfrak{p}}$ is surjective too. Hence (3) \Rightarrow (4). If (4) holds, then $\alpha_{\mathfrak{p}}$ is an isomorphism, so α is injective as $S_{\mathfrak{q}} \rightarrow S_{\mathfrak{p}}$ is injective. Namely, elements of $S \setminus \mathfrak{p}$ are nonzerodivisors on S by a combination of Lemmas 37.7.6 and 37.9.3. Hence (4) \Rightarrow (5). Finally, if (5) holds, then $N_{\mathfrak{q}}$ is R -flat as an extension of flat modules, see Algebra, Lemma 10.38.12. Hence (5) \Rightarrow (1) and the proof is finished. \square

Lemma 37.10.2. *Let (R, \mathfrak{m}) be a local ring. Let $R \rightarrow S$ be a ring map of finite presentation. Let N be a finite S -module. Let \mathfrak{q} be a prime of S lying over \mathfrak{m} . Assume that $N_{\mathfrak{q}}$ is flat over R , and assume there exists a complete dévissage of $N/S/R$ at \mathfrak{q} . Then N is a finitely presented S -module, free as an R -module, and there exists an isomorphism*

$$N \cong B_1^{\oplus r_1} \oplus \dots \oplus B_n^{\oplus r_n}$$

as R -modules where each B_i is a smooth R -algebra with geometrically irreducible fibres.

Proof. Let $(A_i, B_i, M_i, \alpha_i, \mathfrak{q}_i)_{i=1, \dots, n}$ be the given complete dévissage. We prove the lemma by induction on n . Note that N is finitely presented as an S -module if and only if M_1 is finitely presented as an B_1 -module, see Remark 37.6.3. Note that $N_{\mathfrak{q}} \cong (M_1)_{\mathfrak{q}_1}$ as R -modules because (a) $N_{\mathfrak{q}} \cong (M_1)_{\mathfrak{q}'_1}$ where \mathfrak{q}'_1 is the unique prime in A_1 lying over \mathfrak{q}_1 and (b) $(A_1)_{\mathfrak{q}'_1} = (A_1)_{\mathfrak{q}_1}$ by Algebra, Lemma 10.40.11, so (c) $(M_1)_{\mathfrak{q}'_1} \cong (M_1)_{\mathfrak{q}_1}$. Hence $(M_1)_{\mathfrak{q}_1}$ is a flat R -module. Thus we may replace (S, N) by (B_1, M_1) in order to prove the lemma. By Lemma 37.10.1 the map $\alpha_1 : B_1^{\oplus r_1} \rightarrow M_1$ is R -universally injective and $\text{Coker}(\alpha_1)_{\mathfrak{q}}$ is R -flat. Note that $(A_i, B_i, M_i, \alpha_i, \mathfrak{q}_i)_{i=2, \dots, n}$ is a complete dévissage of $\text{Coker}(\alpha_1)/B_1/R$ at \mathfrak{q}_1 . Hence the induction hypothesis implies that $\text{Coker}(\alpha_1)$ is finitely presented as a B_1 -module, free as an R -module, and has a decomposition as in the lemma. This implies that M_1 is finitely presented as a B_1 -module, see Algebra, Lemma 10.5.3. It further implies that $M_1 \cong B_1^{\oplus r_1} \oplus \text{Coker}(\alpha_1)$ as R -modules, hence a decomposition as in the lemma. Finally, B_1 is projective as an R -module by Lemma 37.9.3 hence free as an R -module by Algebra, Theorem 10.82.4. This finishes the proof. \square

Proposition 37.10.3. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $x \in X$ with image $s \in S$. Assume that*

- (1) f is locally of finite presentation,
- (2) \mathcal{F} is of finite type, and
- (3) \mathcal{F} is flat at x over S .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme

$$V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$$

which contains the unique point of $X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ mapping to x such that the pullback of \mathcal{F} to V is an \mathcal{O}_V -module of finite presentation and flat over $\mathcal{O}_{S', s'}$.

First proof. This proof is longer but does not use the existence of a complete dévissage. The problem is local around x and s , hence we may assume that X and S are affine. During the proof we will finitely many times replace S by an elementary étale neighbourhood of (S, s) . The goal is then to find (after such a replacement) an open $V \subset X \times_S \text{Spec}(\mathcal{O}_{S,s})$ containing x such that $\mathcal{F}|_V$ is flat over S and finitely presented. Of course we may also replace S by $\text{Spec}(\mathcal{O}_{S,s})$ at any point of the proof, i.e., we may assume S is a local scheme. We will prove the lemma by induction on the integer $n = \dim_x(\text{Supp}(\mathcal{F}_s))$.

We can choose

- (1) elementary étale neighbourhoods $g : (X', x') \rightarrow (X, x)$, $e : (S', s') \rightarrow (S, s)$,
- (2) a commutative diagram

$$\begin{array}{ccccc}
 X & \xleftarrow{g} & X' & \xleftarrow{i} & Z' \\
 \downarrow f & & \downarrow & & \downarrow \pi \\
 & & & & Y' \\
 & & & & \downarrow h \\
 S & \xleftarrow{e} & S' & \xlongequal{\quad} & S'
 \end{array}$$

- (3) a point $z' \in Z'$ with $i(z') = x'$, $y' = \pi(z')$, $h(y') = s'$,
- (4) a finite type quasi-coherent $\mathcal{O}_{Z'}$ -module \mathcal{G} ,

as in Lemma 37.3.2. We are going to replace S by $\text{Spec}(\mathcal{O}_{S',s'})$, see remarks in first paragraph of the proof. Consider the diagram

$$\begin{array}{ccccc}
 X_{\mathcal{O}_{S',s'}} & \xleftarrow{g} & X'_{\mathcal{O}_{S',s'}} & \xleftarrow{i} & Z'_{\mathcal{O}_{S',s'}} \\
 \searrow f & & \downarrow & & \downarrow \pi \\
 & & & & Y'_{\mathcal{O}_{S',s'}} \\
 & & & & \swarrow h \\
 & & & & \text{Spec}(\mathcal{O}_{S',s'})
 \end{array}$$

Here we have base changed the schemes X', Z', Y' over S' via $\text{Spec}(\mathcal{O}_{S',s'}) \rightarrow S'$ and the scheme X over S via $\text{Spec}(\mathcal{O}_{S',s'}) \rightarrow S$. It is still the case that g is étale, see Lemma 37.2.2. After replacing X by $X_{\mathcal{O}_{S',s'}}$, X' by $X'_{\mathcal{O}_{S',s'}}$, Z' by $Z'_{\mathcal{O}_{S',s'}}$, and Y' by $Y'_{\mathcal{O}_{S',s'}}$ we may assume we have a diagram as Lemma 37.3.2 where in addition $S = S'$ is a local scheme with closed point s . By Lemmas 37.3.3 and 37.3.4 the result for $Y' \rightarrow S$, the sheaf $\pi_*\mathcal{G}$, and the point y' implies the result for $X \rightarrow S$, \mathcal{F} and x . Hence we may assume that S is local and $X \rightarrow S$ is a smooth morphism of affines with geometrically irreducible fibres of dimension n .

The base case of the induction: $n = 0$. As $X \rightarrow S$ is smooth with geometrically irreducible fibres of dimension 0 we see that $X \rightarrow S$ is an open immersion, see Descent, Lemma 34.21.2. As S is local and the closed point is in the image of $X \rightarrow S$ we conclude that $X = S$. Thus we see that \mathcal{F} corresponds to a finite flat $\mathcal{O}_{S,s}$ module. In this case the result follows from Algebra, Lemma 10.75.4 which tells us that \mathcal{F} is in fact finite free.

The induction step. Assume the result holds whenever the dimension of the support in the closed fibre is $< n$. Write $S = \text{Spec}(A)$, $X = \text{Spec}(B)$ and $\mathcal{F} = \widetilde{N}$ for some B -module N . Note that A is a local ring; denote its maximal ideal \mathfrak{m} . Then $\mathfrak{p} = \mathfrak{m}B$ is the unique minimal prime lying over \mathfrak{m} as $X \rightarrow S$ has geometrically irreducible fibres. Finally, let $\mathfrak{q} \subset B$ be the prime corresponding to x . By Lemma 37.10.1 we can choose a map

$$\alpha : B^{\oplus r} \rightarrow N$$

such that $\kappa(\mathfrak{p})^{\oplus r} \rightarrow N \otimes_B \kappa(\mathfrak{p})$ is an isomorphism. Moreover, as $N_{\mathfrak{q}}$ is A -flat the lemma also shows that α is injective and that $\text{Coker}(\alpha)_{\mathfrak{q}}$ is A -flat. Set $Q = \text{Coker}(\alpha)$. Note that the support of $Q/\mathfrak{m}Q$ does not contain \mathfrak{p} . Hence it is certainly the case that $\dim_{\mathfrak{q}}(\text{Supp}(Q/\mathfrak{m}Q)) < n$. Combining everything we know about Q we see that the induction hypothesis applies to Q . It follows that there exists an elementary étale morphism $(S', s) \rightarrow (S, s)$ such that the conclusion holds for $Q \otimes_A A'$ over $B \otimes_A A'$ where $A' = \mathcal{O}_{S', s'}$. After replacing A by A' we have an exact sequence

$$0 \rightarrow B^{\oplus r} \rightarrow N \rightarrow Q \rightarrow 0$$

(here we use that α is injective as mentioned above) of finite B -modules and we also get an element $g \in B$, $g \notin \mathfrak{q}$ such that Q_g is finitely presented over B_g and flat over A . Since localization is exact we see that

$$0 \rightarrow B_g^{\oplus r} \rightarrow N_g \rightarrow Q_g \rightarrow 0$$

is still exact. As B_g and Q_g are flat over A we conclude that N_g is flat over A , see Algebra, Lemma 10.38.12, and as B_g and Q_g are finitely presented over B_g the same holds for N_g , see Algebra, Lemma 10.5.3. \square

Second proof. We apply Proposition 37.5.7 to find a commutative diagram

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (S', s') \end{array}$$

of pointed schemes such that the horizontal arrows are elementary étale neighbourhoods and such that $g^*\mathcal{F}/X'/S'$ has a complete dévissage at x . (In particular S' and X' are affine.) By Morphisms, Lemma 28.26.11 we see that $g^*\mathcal{F}$ is flat at x' over S and by Lemma 37.2.3 we see that it is flat at x' over S' . Via Remark 37.6.5 we deduce that

$$\Gamma(X', g^*\mathcal{F})/\Gamma(X', \mathcal{O}_{X'})/\Gamma(S', \mathcal{O}_{S'})$$

has a complete dévissage at the prime of $\Gamma(X', \mathcal{O}_{X'})$ corresponding to x' . We may base change this complete dévissage to the local ring $\mathcal{O}_{S', s'}$ of $\Gamma(S', \mathcal{O}_{S'})$ at the prime corresponding to s' . Thus Lemma 37.10.2 implies that

$$\Gamma(X', \mathcal{F}) \otimes_{\Gamma(S', \mathcal{O}_{S'})} \mathcal{O}_{S', s'}$$

is flat over $\mathcal{O}_{S', s'}$ and of finite presentation over $\Gamma(X', \mathcal{O}_{X'}) \otimes_{\Gamma(S', \mathcal{O}_{S'})} \mathcal{O}_{S', s'}$. In other words, the restriction of \mathcal{F} to $X' \times_{S'} \text{Spec}(\mathcal{O}_{S', s'})$ is of finite presentation and flat over $\mathcal{O}_{S', s'}$. Since the morphism $X' \times_{S'} \text{Spec}(\mathcal{O}_{S', s'}) \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ is étale (Lemma 37.2.2) its image $V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ is an open subscheme, and by étale descent the restriction of \mathcal{F} to V is of finite presentation and flat over $\mathcal{O}_{S', s'}$. (Results used: Morphisms, Lemma 28.37.13, Descent, Lemma 34.6.3, and Morphisms, Lemma 28.26.11.) \square

Lemma 37.10.4. *Let $f : X \rightarrow S$ be a morphism of schemes which is locally of finite type. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. Let $s \in S$. Then the set*

$$\{x \in X_s \mid \mathcal{F} \text{ flat over } S \text{ at } x\}$$

is open in the fibre X_s .

Proof. Suppose $x \in U$. Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and open $V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ as in Proposition 37.10.3. Note that $X_{s'} = X_s$ as $\kappa(s) = \kappa(s')$. If $x' \in V \cap X_{s'}$, then the pullback of \mathcal{F} to $X \times_S S'$ is flat over S' at x' . Hence \mathcal{F} is flat at x' over S , see Morphisms, Lemma 28.26.11. In other words $X_s \cap V \subset U$ is an open neighbourhood of x in U . \square

Lemma 37.10.5. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $x \in X$ with image $s \in S$. Assume that*

- (1) f is locally of finite type,
- (2) \mathcal{F} is of finite type, and
- (3) \mathcal{F} is flat at x over S .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme

$$V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$$

which contains the unique point of $X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ mapping to x such that the pullback of \mathcal{F} to V is flat over $\mathcal{O}_{S', s'}$.

Proof. (The only difference between this and Proposition 37.10.3 is that we do not assume f is of finite presentation.) The question is local on X and S , hence we may assume X and S are affine. Write $X = \text{Spec}(B)$, $S = \text{Spec}(A)$ and write $B = A[x_1, \dots, x_n]/I$. In other words we obtain a closed immersion $i : X \rightarrow \mathbf{A}_S^n$. Denote $t = i(x) \in \mathbf{A}_S^n$. We may apply Proposition 37.10.3 to $\mathbf{A}_S^n \rightarrow S$, the sheaf $i_*\mathcal{F}$ and the point t . We obtain an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme

$$W \subset \mathbf{A}_{\mathcal{O}_{S', s'}}^n$$

such that the pullback of $i_*\mathcal{F}$ to W is flat over $\mathcal{O}_{S', s'}$. This means that $V := W \cap (X \times_S \text{Spec}(\mathcal{O}_{S', s'}))$ is the desired open subscheme. \square

Lemma 37.10.6. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $s \in S$. Assume that*

- (1) f is of finite presentation,
- (2) \mathcal{F} is of finite type, and
- (3) \mathcal{F} is flat over S at every point of the fibre X_s .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme

$$V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$$

which contains the fibre $X_s = X \times_S s'$ such that the pullback of \mathcal{F} to V is an \mathcal{O}_V -module of finite presentation and flat over $\mathcal{O}_{S', s'}$.

Proof. For every point $x \in X_s$ we can use Proposition 37.10.3 to find an elementary étale neighbourhood $(S_x, s_x) \rightarrow (S, s)$ and an open $V_x \subset X \times_S \text{Spec}(\mathcal{O}_{S_x, s_x})$ such that $x \in X_s = X \times_S s_x$ is contained in V_x and such that the pullback of \mathcal{F} to V_x is an \mathcal{O}_{V_x} -module of finite presentation and flat over \mathcal{O}_{S_x, s_x} . In particular we may

view the fibre $(V_x)_{s_x}$ as an open neighbourhood of x in X_s . Because X_s is quasi-compact we can find a finite number of points $x_1, \dots, x_n \in X_s$ such that X_s is the union of the $(V_{x_i})_{s_{x_i}}$. Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ which dominates each of the neighbourhoods (S_{x_i}, s_{x_i}) , see More on Morphisms, Lemma 36.27.4. Set $V = \bigcup V_i$ where V_i is the inverse images of the open V_{x_i} via the morphism

$$X \times_S \text{Spec}(\mathcal{O}_{S', s'}) \longrightarrow X \times_S \text{Spec}(\mathcal{O}_{S_{x_i}, s_{x_i}})$$

By construction V contains X_s and by construction the pullback of \mathcal{F} to V is an \mathcal{O}_V -module of finite presentation and flat over $\mathcal{O}_{S', s'}$. \square

Lemma 37.10.7. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $s \in S$. Assume that*

- (1) f is of finite type,
- (2) \mathcal{F} is of finite type, and
- (3) \mathcal{F} is flat over S at every point of the fibre X_s .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme

$$V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$$

which contains the fibre $X_s = X \times_S s'$ such that the pullback of \mathcal{F} to V is flat over $\mathcal{O}_{S', s'}$.

Proof. (The only difference between this and Lemma 37.10.6 is that we do not assume f is of finite presentation.) For every point $x \in X_s$ we can use Lemma 37.10.5 to find an elementary étale neighbourhood $(S_x, s_x) \rightarrow (S, s)$ and an open $V_x \subset X \times_S \text{Spec}(\mathcal{O}_{S_x, s_x})$ such that $x \in X_s = X \times_S s_x$ is contained in V_x and such that the pullback of \mathcal{F} to V_x is flat over \mathcal{O}_{S_x, s_x} . In particular we may view the fibre $(V_x)_{s_x}$ as an open neighbourhood of x in X_s . Because X_s is quasi-compact we can find a finite number of points $x_1, \dots, x_n \in X_s$ such that X_s is the union of the $(V_{x_i})_{s_{x_i}}$. Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ which dominates each of the neighbourhoods (S_{x_i}, s_{x_i}) , see More on Morphisms, Lemma 36.27.4. Set $V = \bigcup V_i$ where V_i is the inverse images of the open V_{x_i} via the morphism

$$X \times_S \text{Spec}(\mathcal{O}_{S', s'}) \longrightarrow X \times_S \text{Spec}(\mathcal{O}_{S_{x_i}, s_{x_i}})$$

By construction V contains X_s and by construction the pullback of \mathcal{F} to V is flat over $\mathcal{O}_{S', s'}$. \square

Lemma 37.10.8. *Let S be a scheme. Let X be locally of finite type over S . Let $x \in X$ with image $s \in S$. If X is flat at x over S , then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme*

$$V \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$$

which contains the unique point of $X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ mapping to x such that $V \rightarrow \text{Spec}(\mathcal{O}_{S', s'})$ is flat and of finite presentation.

Proof. The question is local on X and S , hence we may assume X and S are affine. Write $X = \text{Spec}(B)$, $S = \text{Spec}(A)$ and write $B = A[x_1, \dots, x_n]/I$. In other words we obtain a closed immersion $i : X \rightarrow \mathbf{A}_S^n$. Denote $t = i(x) \in \mathbf{A}_S^n$. We may apply

Proposition 37.10.3 to $\mathbf{A}_S^n \rightarrow S$, the sheaf $\mathcal{F} = i_*\mathcal{O}_X$ and the point t . We obtain an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an open subscheme

$$W \subset \mathbf{A}_{\mathcal{O}_{S',s'}}^n$$

such that the pullback of $i_*\mathcal{O}_X$ is flat and of finite presentation. This means that $V := W \cap (X \times_S \text{Spec}(\mathcal{O}_{S',s'}))$ is the desired open subscheme. \square

Lemma 37.10.9. *Let $f : X \rightarrow S$ be a morphism which is locally of finite presentation. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. If $x \in X$ and \mathcal{F} is flat at x over S , then \mathcal{F}_x is an $\mathcal{O}_{X,x}$ -module of finite presentation.*

Proof. Let $s = f(x)$. By Proposition 37.10.3 there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ such that the pullback of \mathcal{F} to $X \times_S \text{Spec}(\mathcal{O}_{S',s'})$ is of finite presentation in a neighbourhood of the point $x' \in X_{s'} = X_s$ corresponding to x . The ring map

$$\mathcal{O}_{X,x} \longrightarrow \mathcal{O}_{X \times_S \text{Spec}(\mathcal{O}_{S',s'}),x'} = \mathcal{O}_{X \times_S S',x'}$$

is flat and local as a localization of an étale ring map. Hence \mathcal{F}_x is of finite presentation over $\mathcal{O}_{X,x}$ by descent, see Algebra, Lemma 10.80.2 (and also that a flat local ring map is faithfully flat, see Algebra, Lemma 10.38.16). \square

Lemma 37.10.10. *Let $f : X \rightarrow S$ be a morphism which is locally of finite type. Let $x \in X$ with image $s \in S$. If f is flat at x over S , then $\mathcal{O}_{X,x}$ is essentially of finite presentation over $\mathcal{O}_{S,s}$.*

Proof. We may assume X and S affine. Write $X = \text{Spec}(B)$, $S = \text{Spec}(A)$ and write $B = A[x_1, \dots, x_n]/I$. In other words we obtain a closed immersion $i : X \rightarrow \mathbf{A}_S^n$. Denote $t = i(x) \in \mathbf{A}_S^n$. We may apply Lemma 37.10.9 to $\mathbf{A}_S^n \rightarrow S$, the sheaf $\mathcal{F} = i_*\mathcal{O}_X$ and the point t . We conclude that $\mathcal{O}_{X,x}$ is of finite presentation over $\mathcal{O}_{\mathbf{A}_S^n,t}$ which implies what we want. \square

Lemma 37.10.11. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. Let $U \subset S$ be open. Assume*

- (1) f is locally of finite presentation,
- (2) \mathcal{F} is of finite type and flat over S ,
- (3) $U \subset S$ is retrocompact and scheme theoretically dense,
- (4) $\mathcal{F}|_{f^{-1}U}$ is of finite presentation.

Then \mathcal{F} is of finite presentation.

Proof. The problem is local on X and S , hence we may assume X and S affine. Write $S = \text{Spec}(A)$ and $X = \text{Spec}(B)$. Let N be a finite B -module such that \mathcal{F} is the quasi-coherent sheaf associated to N . We have $U = D(f_1) \cup \dots \cup D(f_n)$ for some $f_i \in A$, see Algebra, Lemma 10.28.1. As U is schematically dense the map $A \rightarrow A_{f_1} \times \dots \times A_{f_n}$ is injective. Pick a prime $\mathfrak{q} \subset B$ lying over $\mathfrak{p} \subset A$ corresponding to $x \in X$ mapping to $s \in S$. By Lemma 37.10.9 the module $N_{\mathfrak{q}}$ is of finite presentation over $B_{\mathfrak{q}}$. Choose a surjection $\varphi : B^{\oplus m} \rightarrow N$ of B -modules. Choose $k_1, \dots, k_t \in \text{Ker}(\varphi)$ and set $N' = B^{\oplus m} / \sum Bk_j$. There is a canonical surjection $N' \rightarrow N$ and N is the filtered colimit of the B -modules N' constructed in this manner. Thus we see that we can choose k_1, \dots, k_t such that (a) $N'_{f_i} \cong N_{f_i}$, $i = 1, \dots, n$ and (b) $N'_{\mathfrak{q}} \cong N_{\mathfrak{q}}$. This in particular implies that $N'_{\mathfrak{q}}$ is flat over A . By

openness of flatness, see Algebra, Theorem 10.125.4 we conclude that there exists a $g \in B$, $g \notin \mathfrak{q}$ such that N'_g is flat over A . Consider the commutative diagram

$$\begin{array}{ccc} N'_g & \longrightarrow & N_g \\ \downarrow & & \downarrow \\ \prod N'_{gf_i} & \longrightarrow & \prod N_{gf_i} \end{array}$$

The bottom arrow is an isomorphism by choice of k_1, \dots, k_t . The left vertical arrow is an injective map as $A \rightarrow \prod A_{f_i}$ is injective and N'_g is flat over A . Hence the top horizontal arrow is injective, hence an isomorphism. This proves that N_g is of finite presentation over B_g . We conclude by applying Algebra, Lemma 10.23.2. \square

Lemma 37.10.12. *Let $f : X \rightarrow S$ be a morphism of schemes. Let $U \subset S$ be open. Assume*

- (1) f is locally of finite type and flat,
- (2) $U \subset S$ is retrocompact and scheme theoretically dense,
- (3) $f|_{f^{-1}U} : f^{-1}U \rightarrow U$ is locally of finite presentation.

Then f is locally of finite presentation.

Proof. The question is local on X and S , hence we may assume X and S affine. Choose a closed immersion $i : X \rightarrow \mathbf{A}^n_S$ and apply Lemma 37.10.11 to $i_*\mathcal{O}_X$. Some details omitted. \square

37.11. Flat finitely presented modules

In some cases given a ring map $R \rightarrow S$ of finite presentation and a finitely presented S -module N the flatness of N over R implies that N is projective as an R -module, at least after replacing S by an étale extension. In this section we collect some results of this nature.

Lemma 37.11.1. *Let R be a ring. Let $R \rightarrow S$ be a finitely presented flat ring map with geometrically integral fibres. Let $\mathfrak{q} \subset S$ be a prime ideal lying over the prime $\mathfrak{r} \subset R$. Set $\mathfrak{p} = \mathfrak{r}S$. Let N be a finitely presented S -module. There exists $r \geq 0$ and an S -module map*

$$\alpha : S^{\oplus r} \longrightarrow N$$

such that $\alpha : \kappa(\mathfrak{p})^{\oplus r} \rightarrow N \otimes_S \kappa(\mathfrak{p})$ is an isomorphism. For any such α the following are equivalent:

- (1) $N_{\mathfrak{q}}$ is R -flat,
- (2) there exists an $f \in R$, $f \notin \mathfrak{r}$ such that $\alpha_f : S_f^{\oplus r} \rightarrow N_f$ is R_f -universally injective and a $g \in S$, $g \notin \mathfrak{q}$ such that $\text{Coker}(\alpha)_g$ is R -flat,
- (3) $\alpha_{\mathfrak{r}}$ is $R_{\mathfrak{r}}$ -universally injective and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat
- (4) $\alpha_{\mathfrak{r}}$ is injective and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat,
- (5) $\alpha_{\mathfrak{p}}$ is an isomorphism and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat, and
- (6) $\alpha_{\mathfrak{q}}$ is injective and $\text{Coker}(\alpha)_{\mathfrak{q}}$ is R -flat.

Proof. To obtain α set $r = \dim_{\kappa(\mathfrak{p})} N \otimes_S \kappa(\mathfrak{p})$ and pick $x_1, \dots, x_r \in N$ which form a basis of $N \otimes_S \kappa(\mathfrak{p})$. Define $\alpha(s_1, \dots, s_r) = \sum s_i x_i$. This proves the existence.

Fix a choice of α . We may apply Lemma 37.10.1 to the map $\alpha_{\mathfrak{r}} : S_{\mathfrak{r}}^{\oplus r} \rightarrow N_{\mathfrak{r}}$. Hence we see that (1), (3), (4), (5), and (6) are all equivalent. Since it is also clear that (2) implies (3) we see that all we have to do is show that (1) implies (2).

Assume (1). By openness of flatness, see Algebra, Theorem 10.125.4, the set

$$U_1 = \{\mathfrak{q}' \subset S \mid N_{\mathfrak{q}'} \text{ is flat over } R\}$$

is open in $\text{Spec}(S)$. It contains \mathfrak{q} by assumption and hence \mathfrak{p} . Because $S^{\oplus r}$ and N are finitely presented S -modules the set

$$U_2 = \{\mathfrak{q}' \subset S \mid \alpha_{\mathfrak{q}'} \text{ is an isomorphism}\}$$

is open in $\text{Spec}(S)$, see Algebra, Lemma 10.76.2. It contains \mathfrak{p} by (5). As $R \rightarrow S$ is finitely presented and flat the map $\Phi : \text{Spec}(S) \rightarrow \text{Spec}(R)$ is open, see Algebra, Proposition 10.40.8. For any prime $\mathfrak{r}' \in \Phi(U_1 \cap U_2)$ we see that there exists a prime \mathfrak{q}' lying over \mathfrak{r}' such that $N_{\mathfrak{q}'}$ is flat and such that $\alpha_{\mathfrak{q}'}$ is an isomorphism, which implies that $\alpha \otimes \kappa(\mathfrak{p}')$ is an isomorphism where $\mathfrak{p}' = \mathfrak{r}'S$. Thus $\alpha_{\mathfrak{r}'}$ is $R_{\mathfrak{r}'}$ -universally injective by the implication (1) \Rightarrow (3). Hence if we pick $f \in R$, $f \notin \mathfrak{r}$ such that $D(f) \subset \Phi(U_1 \cap U_2)$ then we conclude that α_f is R_f -universally injective, see Algebra, Lemma 10.79.12. The same reasoning also shows that for any $\mathfrak{q}' \in U_1 \cap \Phi^{-1}(\Phi(U_1 \cap U_2))$ the module $\text{Coker}(\alpha)_{\mathfrak{q}'}$ is R -flat. Note that $\mathfrak{q} \in U_1 \cap \Phi^{-1}(\Phi(U_1 \cap U_2))$. Hence we can find a $g \in S$, $g \notin \mathfrak{q}$ such that $D(g) \subset U_1 \cap \Phi^{-1}(\Phi(U_1 \cap U_2))$ and we win. \square

Lemma 37.11.2. *Let $R \rightarrow S$ be a ring map of finite presentation. Let N be a finitely presented S -module flat over R . Let $\mathfrak{r} \subset R$ be a prime ideal. Assume there exists a complete dévissage of $N/S/R$ over \mathfrak{r} . Then there exists an $f \in R$, $f \notin \mathfrak{r}$ such that*

$$N_f \cong B_1^{\oplus r_1} \oplus \dots \oplus B_n^{\oplus r_n}$$

as R -modules where each B_i is a smooth R_f -algebra with geometrically irreducible fibres. Moreover, N_f is projective as an R_f -module.

Proof. Let $(A_i, B_i, M_i, \alpha_i)_{i=1, \dots, n}$ be the given complete dévissage. We prove the lemma by induction on n . Note that the assertions of the lemma are entirely about the structure of N as an R -module. Hence we may replace N by M_1 , and we may think of M_1 as a B_1 -module. See Remark 37.6.3 in order to see why M_1 is of finite presentation as a B_1 -module. By Lemma 37.11.1 we may, after replacing R by R_f for some $f \in R$, $f \notin \mathfrak{r}$, assume the map $\alpha_1 : B_1^{\oplus r_1} \rightarrow M_1$ is R -universally injective. Since M_1 and $B_1^{\oplus r_1}$ are R -flat and finitely presented as B_1 -modules we see that $\text{Coker}(\alpha_1)$ is R -flat (Algebra, Lemma 10.79.7) and finitely presented as a B_1 -module. Note that $(A_i, B_i, M_i, \alpha_i)_{i=2, \dots, n}$ is a complete dévissage of $\text{Coker}(\alpha_1)$. Hence the induction hypothesis implies that, after replacing R by R_f for some $f \in R$, $f \notin \mathfrak{r}$, we may assume that $\text{Coker}(\alpha_1)$ has a decomposition as in the lemma and is projective. In particular $M_1 = B_1^{\oplus r_1} \oplus \text{Coker}(\alpha_1)$. This proves the statement regarding the decomposition. The statement on projectivity follows as B_1 is projective as an R -module by Lemma 37.9.3. \square

Remark 37.11.3. There is a variant of Lemma 37.11.2 where we weaken the flatness condition by assuming only that N is flat at some given prime \mathfrak{q} lying over \mathfrak{r} but where we strengthen the dévissage condition by assuming the existence of a complete dévissage at \mathfrak{q} . Compare with Lemma 37.10.2.

The following is the main result of this section.

Proposition 37.11.4. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $x \in X$ with image $s \in S$. Assume that*

- (1) f is locally of finite presentation,

- (2) \mathcal{F} is of finite presentation, and
- (3) \mathcal{F} is flat at x over S .

Then there exists a commutative diagram of pointed schemes

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (S', s') \end{array}$$

whose horizontal arrows are elementary étale neighbourhoods such that X', S' are affine and such that $\Gamma(X', g^*\mathcal{F})$ is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module.

Proof. By openness of flatness, see More on Morphisms, Theorem 36.12.1 we may replace X by an open neighbourhood of x and assume that \mathcal{F} is flat over S . Next, we apply Proposition 37.5.7 to find a diagram as in the statement of the proposition such that $g^*\mathcal{F}/X'/S'$ has a complete dévissage over s' . (In particular S' and X' are affine.) By Morphisms, Lemma 28.26.11 we see that $g^*\mathcal{F}$ is flat over S and by Lemma 37.2.3 we see that it is flat over S' . Via Remark 37.6.5 we deduce that

$$\Gamma(X', g^*\mathcal{F})/\Gamma(X', \mathcal{O}_{X'})/\Gamma(S', \mathcal{O}_{S'})$$

has a complete dévissage over the prime of $\Gamma(S', \mathcal{O}_{S'})$ corresponding to s' . Thus Lemma 37.11.2 implies that the result of the proposition holds after replacing S' by a standard open neighbourhood of s' . \square

In the rest of this section we prove a number of variants on this result. The first is a “global” version.

Lemma 37.11.5. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $s \in S$. Assume that*

- (1) f is of finite presentation,
- (2) \mathcal{F} is of finite presentation, and
- (3) \mathcal{F} is flat over S at every point of the fibre X_s .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of schemes

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & S' \end{array}$$

such that g is étale, $X_s \subset g(X')$, the schemes X', S' are affine, and such that $\Gamma(X', g^*\mathcal{F})$ is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module.

Proof. For every point $x \in X_s$ we can use Proposition 37.11.4 to find a commutative diagram

$$\begin{array}{ccc} (X, x) & \xleftarrow{g_x} & (Y_x, y_x) \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (S_x, s_x) \end{array}$$

whose horizontal arrows are elementary étale neighbourhoods such that Y_x, S_x are affine and such that $\Gamma(Y_x, g_x^*\mathcal{F})$ is a projective $\Gamma(S_x, \mathcal{O}_{S_x})$ -module. In particular $g_x(Y_x) \cap X_s$ is an open neighbourhood of x in X_s . Because X_s is quasi-compact we

can find a finite number of points $x_1, \dots, x_n \in X_s$ such that X_s is the union of the $g_{x_i}(Y_{x_i}) \cap X_s$. Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ which dominates each of the neighbourhoods (S_{x_i}, s_{x_i}) , see More on Morphisms, Lemma 36.27.4. We may also assume that S' is affine. Set $X' = \coprod Y_{x_i} \times_{S_{x_i}} S'$ and endow it with the obvious morphism $g : X' \rightarrow X$. By construction $g(X')$ contains X_s and

$$\Gamma(X', g^* \mathcal{F}) = \bigoplus \Gamma(Y_{x_i}, g_{x_i}^* \mathcal{F}) \otimes_{\Gamma(S_{x_i}, \mathcal{O}_{S_{x_i}})} \Gamma(S', \mathcal{O}_{S'}).$$

This is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module, see Algebra, Lemma 10.91.1. □

The following two lemmas are reformulations of the results above in case $\mathcal{F} = \mathcal{O}_X$.

Lemma 37.11.6. *Let $f : X \rightarrow S$ be locally of finite presentation. Let $x \in X$ with image $s \in S$. If f is flat at x over S , then there exists a commutative diagram of pointed schemes*

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (S', s') \end{array}$$

whose horizontal arrows are elementary étale neighbourhoods such that X', S' are affine and such that $\Gamma(X', \mathcal{O}_{X'})$ is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module.

Proof. This is a special case of Proposition 37.11.4. □

Lemma 37.11.7. *Let $f : X \rightarrow S$ be of finite presentation. Let $s \in S$. If X is flat over S at all points of X_s , then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of schemes*

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & S' \end{array}$$

with g étale, $X_s \subset g(X')$, such that X', S' are affine, and such that $\Gamma(X', \mathcal{O}_{X'})$ is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module.

Proof. This is a special case of Lemma 37.11.5. □

The following lemmas explain consequences of Proposition 37.11.4 in case we only assume the morphism and the sheaf are of finite type (and not necessarily of finite presentation).

Lemma 37.11.8. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $x \in X$ with image $s \in S$. Assume that*

- (1) f is locally of finite presentation,
- (2) \mathcal{F} is of finite type, and
- (3) \mathcal{F} is flat at x over S .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of pointed schemes

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (\text{Spec}(\mathcal{O}_{S', s'}), s') \end{array}$$

such that $X' \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ is étale, $\kappa(x) = \kappa(x')$, the scheme X' is affine of finite presentation over $\mathcal{O}_{S', s'}$, the sheaf $g^*\mathcal{F}$ is of finite presentation over $\mathcal{O}_{X'}$, and such that $\Gamma(X', g^*\mathcal{F})$ is a free $\mathcal{O}_{S', s'}$ -module.

Proof. To prove the lemma we may replace (S, s) by any elementary étale neighbourhood, and we may also replace S by $\text{Spec}(\mathcal{O}_{S, s})$. Hence by Proposition 37.10.3 we may assume that \mathcal{F} is finitely presented and flat over S in a neighbourhood of x . In this case the result follows from Proposition 37.11.4 because Algebra, Theorem 10.82.4 assures us that projective = free over a local ring. \square

Lemma 37.11.9. Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $x \in X$ with image $s \in S$. Assume that

- (1) f is locally of finite type,
- (2) \mathcal{F} is of finite type, and
- (3) \mathcal{F} is flat at x over S .

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of pointed schemes

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (\text{Spec}(\mathcal{O}_{S', s'}), s') \end{array}$$

such that $X' \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ is étale, $\kappa(x) = \kappa(x')$, the scheme X' is affine, and such that $\Gamma(X', g^*\mathcal{F})$ is a free $\mathcal{O}_{S', s'}$ -module.

Proof. (The only difference with Lemma 37.11.8 is that we do not assume f is of finite presentation.) The problem is local on X and S . Hence we may assume X and S are affine, say $X = \text{Spec}(B)$ and $S = \text{Spec}(A)$. Since B is a finite type A -algebra we can find a surjection $A[x_1, \dots, x_n] \rightarrow B$. In other words, we can choose a closed immersion $i : X \rightarrow \mathbf{A}_S^n$. Set $t = i(x)$ and $\mathcal{G} = i_*\mathcal{F}$. Note that $\mathcal{G}_t \cong \mathcal{F}_x$ are $\mathcal{O}_{S, s}$ -modules. Hence \mathcal{G} is flat over S at t . We apply Lemma 37.11.8 to the morphism $\mathbf{A}_S^n \rightarrow S$, the point t , and the sheaf \mathcal{G} . Thus we can find an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of pointed schemes

$$\begin{array}{ccc} (\mathbf{A}_S^n, t) & \xleftarrow{h} & (Y, y) \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (\text{Spec}(\mathcal{O}_{S', s'}), s') \end{array}$$

such that $Y \rightarrow \mathbf{A}_{\mathcal{O}_{S', s'}}^n$ is étale, $\kappa(t) = \kappa(y)$, the scheme Y is affine, and such that $\Gamma(Y, h^*\mathcal{G})$ is a projective $\mathcal{O}_{S', s'}$ -module. Then a solution to the original problem is given by the closed subscheme $X' = Y \times_{\mathbf{A}_S^n} X$ of Y . \square

Lemma 37.11.10. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $s \in S$. Assume that*

- (1) *f is of finite presentation,*
- (2) *\mathcal{F} is of finite type, and*
- (3) *\mathcal{F} is flat over S at all points of X_s .*

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of schemes

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & \text{Spec}(\mathcal{O}_{S', s'}) \end{array}$$

such that $X' \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ is étale, $X_s = g((X')_{s'})$, the scheme X' is affine of finite presentation over $\mathcal{O}_{S', s'}$, the sheaf $g^\mathcal{F}$ is of finite presentation over $\mathcal{O}_{X'}$, and such that $\Gamma(X', g^*\mathcal{F})$ is a free $\mathcal{O}_{S', s'}$ -module.*

Proof. For every point $x \in X_s$ we can use Lemma 37.11.8 to find an elementary étale neighbourhood $(S_x, s_x) \rightarrow (S, s)$ and a commutative diagram

$$\begin{array}{ccc} (X, x) & \xleftarrow{g_x} & (Y_x, y_x) \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (\text{Spec}(\mathcal{O}_{S_x, s_x}), s_x) \end{array}$$

such that $Y_x \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S_x, s_x})$ is étale, $\kappa(x) = \kappa(y_x)$, the scheme Y_x is affine of finite presentation over \mathcal{O}_{S_x, s_x} , the sheaf $g_x^*\mathcal{F}$ is of finite presentation over \mathcal{O}_{Y_x} , and such that $\Gamma(Y_x, g_x^*\mathcal{F})$ is a free \mathcal{O}_{S_x, s_x} -module. In particular $g_x((Y_x)_{s_x})$ is an open neighbourhood of x in X_s . Because X_s is quasi-compact we can find a finite number of points $x_1, \dots, x_n \in X_s$ such that X_s is the union of the $g_{x_i}((Y_{x_i})_{s_{x_i}})$. Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ which dominates each of the neighbourhoods (S_{x_i}, s_{x_i}) , see More on Morphisms, Lemma 36.27.4. Set

$$X' = \coprod Y_{x_i} \times_{\text{Spec}(\mathcal{O}_{S_{x_i}, s_{x_i}})} \text{Spec}(\mathcal{O}_{S', s'})$$

and endow it with the obvious morphism $g : X' \rightarrow X$. By construction $X_s = g(X'_{s'})$ and

$$\Gamma(X', g^*\mathcal{F}) = \bigoplus \Gamma(Y_{x_i}, g_{x_i}^*\mathcal{F}) \otimes_{\mathcal{O}_{S_{x_i}, s_{x_i}}} \mathcal{O}_{S', s'}.$$

This is a free $\mathcal{O}_{S', s'}$ -module as a direct sum of base changes of free modules. Some minor details omitted. □

Lemma 37.11.11. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent sheaf on X . Let $s \in S$. Assume that*

- (1) *f is of finite type,*
- (2) *\mathcal{F} is of finite type, and*
- (3) *\mathcal{F} is flat over S at all points of X_s .*

Then there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram of schemes

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & \text{Spec}(\mathcal{O}_{S', s'}) \end{array}$$

such that $X' \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ is étale, $X_s = g((X')_{s'})$, the scheme X' is affine, and such that $\Gamma(X', g^* \mathcal{F})$ is a free $\mathcal{O}_{S', s'}$ -module.

Proof. (The only difference with Lemma 37.11.10 is that we do not assume f is of finite presentation.) For every point $x \in X_s$ we can use Lemma 37.11.9 to find an elementary étale neighbourhood $(S_x, s_x) \rightarrow (S, s)$ and a commutative diagram

$$\begin{array}{ccc} (X, x) & \xleftarrow{g_x} & (Y_x, y_x) \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{\quad} & (\text{Spec}(\mathcal{O}_{S_x, s_x}), s_x) \end{array}$$

such that $Y_x \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S_x, s_x})$ is étale, $\kappa(x) = \kappa(y_x)$, the scheme Y_x is affine, and such that $\Gamma(Y_x, g_x^* \mathcal{F})$ is a free \mathcal{O}_{S_x, s_x} -module. In particular $g_x((Y_x)_{s_x})$ is an open neighbourhood of x in X_s . Because X_s is quasi-compact we can find a finite number of points $x_1, \dots, x_n \in X_s$ such that X_s is the union of the $g_{x_i}((Y_{x_i})_{s_{x_i}})$. Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ which dominates each of the neighbourhoods (S_{x_i}, s_{x_i}) , see More on Morphisms, Lemma 36.27.4. Set

$$X' = \coprod Y_{x_i} \times_{\text{Spec}(\mathcal{O}_{S_{x_i}, s_{x_i}})} \text{Spec}(\mathcal{O}_{S', s'})$$

and endow it with the obvious morphism $g : X' \rightarrow X$. By construction $X_s = g(X'_{s'})$ and

$$\Gamma(X', g^* \mathcal{F}) = \bigoplus \Gamma(Y_{x_i}, g_{x_i}^* \mathcal{F}) \otimes_{\mathcal{O}_{S_{x_i}, s_{x_i}}} \mathcal{O}_{S', s'}.$$

This is a free $\mathcal{O}_{S', s'}$ -module as a direct sum of base changes of free modules. \square

37.12. Flat finite type modules, Part II

The following lemma will be superseded by the stronger Lemma 37.12.3 below.

Lemma 37.12.1. *Let (R, \mathfrak{m}) be a local ring. Let $R \rightarrow S$ be of finite presentation. Let N be a finitely presented S -module which is free as an R -module. Let M be an R -module. Let \mathfrak{q} be a prime of S lying over \mathfrak{m} . Then*

- (1) *if $\mathfrak{q} \in \text{WeakAss}_S(M \otimes_R N)$ then $\mathfrak{m} \in \text{WeakAss}_R(M)$ and $\bar{\mathfrak{q}} \in \text{Ass}_{\bar{S}}(\bar{N})$,*
- (2) *if $\mathfrak{m} \in \text{WeakAss}_R(M)$ and $\bar{\mathfrak{q}} \in \text{Ass}_{\bar{S}}(\bar{N})$ is a maximal element then $\mathfrak{q} \in \text{WeakAss}_S(M \otimes_R N)$.*

Here $\bar{S} = S/\mathfrak{m}S$, $\bar{\mathfrak{q}} = \mathfrak{q}\bar{S}$, and $\bar{N} = N/\mathfrak{m}N$.

Proof. Suppose that $\bar{\mathfrak{q}} \notin \text{Ass}_{\bar{S}}(\bar{N})$. By Algebra, Lemmas 10.62.9, 10.62.5, and 10.14.2 there exists an element $\bar{g} \in \bar{\mathfrak{q}}$ which is not a zerodivisor on \bar{N} . Let $g \in \mathfrak{q}$ be an element which maps to \bar{g} in $\bar{\mathfrak{q}}$. By Lemma 37.7.6 the map $g : N \rightarrow N$ is R -universally injective. In particular we see that $g : M \otimes_R N \rightarrow M \otimes_R N$ is injective. Clearly this implies that $\mathfrak{q} \notin \text{WeakAss}_S(M \otimes_R N)$. We conclude that $\mathfrak{q} \in \text{WeakAss}_S(M \otimes_R N)$ implies $\bar{\mathfrak{q}} \in \text{Ass}_{\bar{S}}(\bar{N})$.

Assume $\mathfrak{q} \in \text{WeakAss}_S(M \otimes_R N)$. Let $z \in M \otimes_R N$ be an element whose annihilator in S has radical \mathfrak{q} . As N is a free R -module, we can find a finite free direct summand $F \subset N$ such that $z \in M \otimes_R F$. The radical of the annihilator of $z \in M \otimes_R F$ in R is \mathfrak{m} (by our assumption on z and because \mathfrak{q} lies over \mathfrak{m}). Hence we see that $\mathfrak{m} \in \text{WeakAss}(M \otimes_R F)$ which implies that $\mathfrak{m} \in \text{WeakAss}(M)$ by Algebra, Lemma 10.65.3. This finishes the proof of (1).

Assume that $\mathfrak{m} \in \text{WeakAss}_R(M)$ and $\bar{\mathfrak{q}} \in \text{Ass}_{\bar{S}}(\bar{N})$ is a maximal element. Let $y \in M$ be an element whose annihilator $I = \text{Ann}_R(y)$ has radical \mathfrak{m} . Then $R/I \subset M$ and by flatness of N over R we get $N/IN = R/I \otimes_R N \subset M \otimes_R N$. Hence it is enough to show that $\mathfrak{q} \in \text{WeakAss}(N/IN)$. Write $\bar{\mathfrak{q}} = (\bar{g}_1, \dots, \bar{g}_n)$ for some $\bar{g}_i \in \bar{S}$. Choose lifts $g_i \in \mathfrak{q}$. Consider the map

$$\Psi : N/IN \longrightarrow N/IN^{\oplus n}, \quad z \longmapsto (g_1 z, \dots, g_n z).$$

We may think of this as a map of free R/I -modules. As the ring R/I is auto-associated (since \mathfrak{m}/I is locally nilpotent) and since $\Psi \otimes R/\mathfrak{m}$ isn't injective (since $\bar{\mathfrak{q}} \in \text{Ass}(\bar{N})$) we see by More on Algebra, Lemma 15.8.4 that Ψ isn't injective. Pick $z \in N/IN$ nonzero in the kernel of Ψ . The annihilator of z contains I and g_i , whence its radical $J = \sqrt{\text{Ann}_S(z)}$ contains \mathfrak{q} . Let $\mathfrak{q}' \supset J$ be a minimal prime over J . Then $\mathfrak{q}' \in \text{WeakAss}(M \otimes_R N)$ (by definition) and by (1) we see that $\bar{\mathfrak{q}}' \in \text{Ass}(\bar{N})$. Then since $\mathfrak{q} \subset \mathfrak{q}'$ by construction the maximality of $\bar{\mathfrak{q}}$ implies $\mathfrak{q} = \mathfrak{q}'$ whence $\mathfrak{q} \in \text{WeakAss}(M \otimes_R N)$. This proves part (2) of the lemma. \square

Lemma 37.12.2. *Let S be a scheme. Let $f : X \rightarrow S$ be locally of finite type. Let $x \in X$ with image $s \in S$. Let \mathcal{F} be a finite type quasi-coherent sheaf on X . Let \mathcal{G} be a quasi-coherent sheaf on S . If \mathcal{F} is flat at x over S , then*

$$x \in \text{WeakAss}_X(\mathcal{F} \otimes_{\mathcal{O}_X} f^* \mathcal{G}) \Leftrightarrow s \in \text{WeakAss}_S(\mathcal{G}) \text{ and } x \in \text{Ass}_{X_s}(\mathcal{F}_s).$$

Proof. The question is local on X and S , hence we may assume X and S are affine. Write $X = \text{Spec}(B)$, $S = \text{Spec}(A)$ and write $B = A[x_1, \dots, x_n]/I$. In other words we obtain a closed immersion $i : X \rightarrow \mathbf{A}_S^n$ over S . Denote $t = i(x) \in \mathbf{A}_S^n$. Note that $i_* \mathcal{F}$ is a finite type quasi-coherent sheaf on \mathbf{A}_S^n which is flat at t over S and note that

$$i_*(\mathcal{F} \otimes_{\mathcal{O}_X} f^* \mathcal{G}) = i_* \mathcal{F} \otimes_{\mathcal{O}_{\mathbf{A}_S^n}} p^* \mathcal{G}$$

where $p : \mathbf{A}_S^n \rightarrow S$ is the projection. Note that t is a weakly associated point of $i_*(\mathcal{F} \otimes_{\mathcal{O}_X} f^* \mathcal{G})$ if and only if x is a weakly associated point of $\mathcal{F} \otimes_{\mathcal{O}_X} f^* \mathcal{G}$, see Divisors, Lemma 30.6.3. Similarly $x \in \text{Ass}_{X_s}(\mathcal{F}_s)$ if and only if $t \in \text{Ass}_{\mathbf{A}_S^n}((i_* \mathcal{F})_s)$ (see Algebra, Lemma 10.62.13). Hence it suffices to prove the lemma in case $X = \mathbf{A}_S^n$. In particular we may assume that $X \rightarrow S$ is of finite presentation.

Recall that $\text{Ass}_{X_s}(\mathcal{F}_s)$ is a locally finite subset of the locally Noetherian scheme X_s , see Divisors, Lemma 30.2.5. After replacing X by a suitable affine neighbourhood of x we may assume that

$$(*) \text{ if } x' \in \text{Ass}_{X_s}(\mathcal{F}_s) \text{ and } x \rightsquigarrow x' \text{ then } x = x'.$$

(Proof omitted. Hint: using Algebra, Lemma 10.14.2 invert a function which does not vanish at x but does vanish in all the finitely many points of $\text{Ass}_{X_s}(\mathcal{F}_s)$ which are specializations of x but not equal to x .) In words, no point of $\text{Ass}_{X_s}(\mathcal{F}_s)$ is a proper specialization of x .

Suppose given a commutative diagram

$$\begin{array}{ccc} (X, x) & \xleftarrow{g} & (X', x') \\ \downarrow & & \downarrow \\ (S, s) & \xleftarrow{e} & (S', s') \end{array}$$

of pointed schemes whose horizontal arrows are elementary étale neighbourhoods. Then it suffices to prove the statement for $x', s', g^*\mathcal{F}$ and $e^*\mathcal{G}$, see Lemma 37.2.7. Note that property (*) is preserved by such an étale localization by the same lemma (if there is a proper specialization $x' \rightsquigarrow x''$ on X'_s , then this maps to a proper specialization on X_s because the fibres of an étale morphism are discrete). We may also replace S by the spectrum of its local ring as the condition of being an associated point of a quasi-coherent sheaf depends only on the stalk of the sheaf. Again property (*) is preserved by this as well. Thus we may first apply Proposition 37.10.3 to reduce to the case where \mathcal{F} is of finite presentation and flat over S , whereupon we may use Proposition 37.11.4 to reduce to the case that $X \rightarrow S$ is a morphism of affines and $\Gamma(X, \mathcal{F})$ is a finitely presented $\Gamma(X, \mathcal{O}_X)$ -module which is projective as a $\Gamma(S, \mathcal{O}_S)$ -module. Localizing S once more we may assume that $\Gamma(S, \mathcal{O}_S)$ is a local ring such that s corresponds to the maximal ideal. In this case Algebra, Theorem 10.82.4 guarantees that $\Gamma(X, \mathcal{F})$ is free as an $\Gamma(S, \mathcal{O}_S)$ -module. The implication $x \in \text{WeakAss}_X(\mathcal{F} \otimes_{\mathcal{O}_X} f^*\mathcal{G}) \Rightarrow s \in \text{WeakAss}_S(\mathcal{G})$ and $x \in \text{Ass}_{X_s}(\mathcal{F}_s)$ follows from part (1) of Lemma 37.12.1. The converse implication follows from part (2) of Lemma 37.12.1 as property (*) insures that the prime corresponding to x gives rise to a maximal element of $\text{Ass}_{\overline{S}}(\overline{N})$ exactly as in the statement of part (2) of Lemma 37.12.1. \square

Lemma 37.12.3. *Let $R \rightarrow S$ be a ring map which is essentially of finite type. Let N be a localization of a finite S -module flat over R . Let M be an R -module. Then*

$$\text{WeakAss}_S(M \otimes_R N) = \bigcup_{\mathfrak{p} \in \text{WeakAss}_R(M)} \text{Ass}_{S \otimes_R \kappa(\mathfrak{p})}(N \otimes_R \kappa(\mathfrak{p}))$$

Proof. This lemma is a translation of Lemma 37.12.2 into algebra. Details of translation omitted. \square

Lemma 37.12.4. *Let $f : X \rightarrow S$ be a morphism which is locally of finite type. Let \mathcal{F} be a finite type quasi-coherent sheaf on X which is flat over S . Let \mathcal{G} be a quasi-coherent sheaf on S . Then we have*

$$\text{WeakAss}_X(\mathcal{F} \otimes_{\mathcal{O}_X} f^*\mathcal{G}) = \bigcup_{s \in \text{WeakAss}_S(\mathcal{G})} \text{Ass}_{X_s}(\mathcal{F}_s)$$

Proof. Immediate consequence of Lemma 37.12.2. \square

Theorem 37.12.5. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. Assume*

- (1) $X \rightarrow S$ is locally of finite presentation,
- (2) \mathcal{F} is an \mathcal{O}_X -module of finite type, and
- (3) the set of weakly associated points of S is locally finite in S .

Then $U = \{x \in X \mid \mathcal{F} \text{ flat at } x \text{ over } S\}$ is open in X and $\mathcal{F}|_U$ is an \mathcal{O}_U -module of finite presentation and flat over S .

Proof. Let $x \in X$ be such that \mathcal{F} is flat at x over S . We have to find an open neighbourhood of x such that \mathcal{F} restricts to a S -flat finitely presented module on this neighbourhood. The problem is local on X and S , hence we may assume that X and S are affine. As \mathcal{F}_x is a finitely presented $\mathcal{O}_{X,x}$ -module by Lemma 37.10.9 we conclude from Algebra, Lemma 10.122.5 there exists a finitely presented \mathcal{O}_X -module \mathcal{F}' and a map $\varphi : \mathcal{F}' \rightarrow \mathcal{F}$ which induces an isomorphism $\varphi_x : \mathcal{F}'_x \rightarrow \mathcal{F}_x$. In particular we see that \mathcal{F}' is flat over S at x , hence by openness of flatness More on Morphisms, Theorem 36.12.1 we see that after shrinking X we may assume that \mathcal{F}' is flat over S . As \mathcal{F} is of finite type after shrinking X we may assume that φ is surjective, see Modules, Lemma 17.9.4 or alternatively use Nakayama's lemma (Algebra, Lemma 10.19.1). By Lemma 37.12.4 we have

$$\text{WeakAss}_X(\mathcal{F}') \subset \bigcup_{s \in \text{WeakAss}(S)} \text{Ass}_{X_s}(\mathcal{F}'_s)$$

As $\text{WeakAss}(S)$ is finite by assumption and since $\text{Ass}_{X_s}(\mathcal{F}'_s)$ is finite by Divisors, Lemma 30.2.5 we conclude that $\text{WeakAss}_X(\mathcal{F}')$ is finite. Using Algebra, Lemma 10.14.2 we may, after shrinking X once more, assume that $\text{WeakAss}_X(\mathcal{F}')$ is contained in the generalization of x . Now consider $\mathcal{K} = \text{Ker}(\varphi)$. We have $\text{WeakAss}_X(\mathcal{K}) \subset \text{WeakAss}_X(\mathcal{F}')$ (by Divisors, Lemma 30.5.4) but on the other hand, φ_x is an isomorphism, also $\varphi_{x'}$ is an isomorphism for all $x' \rightsquigarrow x$. We conclude that $\text{WeakAss}_X(\mathcal{K}) = \emptyset$ whence $\mathcal{K} = 0$ by Divisors, Lemma 30.5.5. \square

Lemma 37.12.6. *Let $R \rightarrow S$ be a ring map of finite presentation. Let M be a finite S -module. Assume $\text{WeakAss}_S(S)$ is finite. Then*

$$U = \{\mathfrak{q} \subset S \mid M_{\mathfrak{q}} \text{ flat over } R\}$$

is open in $\text{Spec}(S)$ and for every $g \in S$ such that $D(g) \subset U$ the localization M_g is a finitely presented S_g -module flat over R .

Proof. Follows immediately from Theorem 37.12.5. \square

Lemma 37.12.7. *Let $f : X \rightarrow S$ be a morphism of schemes which is locally of finite type. Assume the set of weakly associated points of S is locally finite in S . Then the set of points $x \in X$ where f is flat is an open subscheme $U \subset X$ and $U \rightarrow S$ is flat and locally of finite presentation.*

Proof. The problem is local on X and S , hence we may assume that X and S are affine. Then $X \rightarrow S$ corresponds to a finite type ring map $A \rightarrow B$. Choose a surjection $A[x_1, \dots, x_n] \rightarrow B$ and consider B as an $A[x_1, \dots, x_n]$ -module. An application of Lemma 37.12.6 finishes the proof. \square

Lemma 37.12.8. *Let $f : X \rightarrow S$ be a morphism of schemes which is locally of finite type and flat. If S is integral, then f is locally of finite presentation.*

Proof. Special case of Lemma 37.12.7. \square

Proposition 37.12.9. *Let R be a domain. Let $R \rightarrow S$ be a ring map of finite type. Let M be a finite S -module.*

- (1) *If S is flat over R , then S is a finitely presented R -algebra.*
- (2) *If M is flat as an R -module, then M is finitely presented as an S -module.*

Proof. Part (1) is a special case of Lemma 37.12.8. For Part (2) choose a surjection $R[x_1, \dots, x_n] \rightarrow S$. By Lemma 37.12.6 we find that M is finitely presented as an $R[x_1, \dots, x_n]$ -module. We conclude by Algebra, Lemma 10.6.4. \square

Remark 37.12.10 (Finite type version of Theorem 37.12.5). Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. Assume

- (1) $X \rightarrow S$ is locally of finite type,
- (2) \mathcal{F} is an \mathcal{O}_X -module of finite type, and
- (3) the set of weakly associated points of S is locally finite in S .

Then $U = \{x \in X \mid \mathcal{F} \text{ flat at } x \text{ over } S\}$ is open in X and $\mathcal{F}|_U$ is flat over S and locally finitely presented relative to S (see More on Morphisms, Definition 36.38.1). If we ever need this result in the stacks project we will convert this remark into a lemma with a proof.

Remark 37.12.11 (Algebra version of Remark 37.12.10). Let $R \rightarrow S$ be a ring map of finite type. Let M be a finite S -module. Assume $\text{WeakAss}_S(S)$ is finite. Then

$$U = \{\mathfrak{q} \subset S \mid M_{\mathfrak{q}} \text{ flat over } R\}$$

is open in $\text{Spec}(S)$ and for every $g \in S$ such that $D(g) \subset U$ the localization M_g is flat over R and an S_g -module finitely presented relative to R (see More on Algebra, Definition 15.58.2). If we ever need this result in the stacks project we will convert this remark into a lemma with a proof.

37.13. Examples of relatively pure modules

In the short section we discuss some examples of results that will serve as motivation for the notion of a *relatively pure module* and the concept of an *impurity* which we will introduce later. Each of the examples is stated as a lemma. Note the similarity with the condition on associated primes to the conditions appearing in Lemmas 37.7.4, 37.8.3, 37.8.4, and 37.9.1. See also Algebra, Lemma 10.64.1 for a discussion.

Lemma 37.13.1. *Let R be a local ring with maximal ideal \mathfrak{m} . Let $R \rightarrow S$ be a ring map. Let N be an S -module. Assume*

- (1) N is projective as an R -module, and
- (2) $S/\mathfrak{m}S$ is Noetherian and $N/\mathfrak{m}N$ is a finite $S/\mathfrak{m}S$ -module.

Then for any prime $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R \kappa(\mathfrak{p})$ where $\mathfrak{p} = R \cap \mathfrak{q}$ we have $\mathfrak{q} + \mathfrak{m}S \neq S$.

Proof. Note that the hypotheses of Lemmas 37.7.1 and 37.7.6 are satisfied. We will use the conclusions of these lemmas without further mention. Let $\Sigma \subset S$ be the multiplicative set of elements which are not zerodivisors on $N/\mathfrak{m}N$. The map $N \rightarrow \Sigma^{-1}N$ is R -universally injective. Hence we see that any $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R \kappa(\mathfrak{p})$ is also an associated prime of $\Sigma^{-1}N \otimes_R \kappa(\mathfrak{p})$. Clearly this implies that \mathfrak{q} corresponds to a prime of $\Sigma^{-1}S$. Thus $\mathfrak{q} \subset \mathfrak{q}'$ where \mathfrak{q}' corresponds to an associated prime of $N/\mathfrak{m}N$ and we win. \square

The following lemma gives another (slightly silly) example of this phenomenon.

Lemma 37.13.2. *Let R be a ring. Let $I \subset R$ be an ideal. Let $R \rightarrow S$ be a ring map. Let N be an S -module. If N is I -adically complete, then for any R -module M and for any prime $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R M$ we have $\mathfrak{q} + IS \neq S$.*

Proof. Let S^\wedge denote the I -adic completion of S . Note that N is an S^\wedge -module, hence also $N \otimes_R M$ is an S^\wedge -module. Let $z \in N \otimes_R M$ be an element such that $\mathfrak{q} = \text{Ann}_S(z)$. Since $z \neq 0$ we see that $\text{Ann}_{S^\wedge}(z) \neq S^\wedge$. Hence $\mathfrak{q}S^\wedge \neq S^\wedge$. Hence

there exists a maximal ideal $\mathfrak{m} \subset S^\wedge$ with $\mathfrak{q}S^\wedge \subset \mathfrak{m}$. Since $IS^\wedge \subset \mathfrak{m}$ by Algebra, Lemma 10.93.11 we win. \square

Note that the following lemma gives an alternative proof of Lemma 37.13.1 as a projective module over a local ring is free, see Algebra, Theorem 10.82.4.

Lemma 37.13.3. *Let R be a local ring with maximal ideal \mathfrak{m} . Let $R \rightarrow S$ be a ring map. Let N be an S -module. Assume N is isomorphic as an R -module to a direct sum of finite R -modules. Then for any R -module M and for any prime $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R M$ we have $\mathfrak{q} + \mathfrak{m}S \neq S$.*

Proof. Write $N = \bigoplus_{i \in I} M_i$ with each M_i a finite R -module. Let M be an R -module and let $\mathfrak{q} \subset S$ be an associated prime of $N \otimes_R M$ such that $\mathfrak{q} + \mathfrak{m}S = S$. Let $z \in N \otimes_R M$ be an element with $\mathfrak{q} = \text{Ann}_S(z)$. After modifying the direct sum decomposition a little bit we may assume that $z \in M_1 \otimes_R M$ for some element $1 \in I$. Write $1 = f + \sum x_j g_j$ for some $f \in \mathfrak{q}$, $x_j \in \mathfrak{m}$, and $g_j \in S$. For any $g \in S$ denote g' the R -linear map

$$M_1 \rightarrow N \xrightarrow{g} N \rightarrow M_1$$

where the first arrow is the inclusion map, the second arrow is multiplication by g and the third arrow is the projection map. Because each $x_j \in R$ we obtain the equality

$$f' + \sum x_j g'_j = \text{id}_{M_1} \in \text{End}_R(M_1)$$

By Nakayama's lemma (Algebra, Lemma 10.19.1) we see that f' is surjective, hence by Algebra, Lemma 10.15.4 we see that f' is an isomorphism. In particular the map

$$M_1 \otimes_R M \rightarrow N \otimes_R M \xrightarrow{f} N \otimes_R M \rightarrow M_1 \otimes_R M$$

is an isomorphism. This contradicts the assumption that $fz = 0$. \square

Lemma 37.13.4. *Let R be a henselian local ring with maximal ideal \mathfrak{m} . Let $R \rightarrow S$ be a ring map. Let N be an S -module. Assume N is countably generated and Mittag-Leffler as an R -module. Then for any R -module M and for any prime $\mathfrak{q} \subset S$ which is an associated prime of $N \otimes_R M$ we have $\mathfrak{q} + \mathfrak{m}S \neq S$.*

Proof. This lemma reduces to Lemma 37.13.3 by Algebra, Lemma 10.145.32. \square

Suppose $f : X \rightarrow S$ is a morphism of schemes and \mathcal{F} is a quasi-coherent module on X . Let $\xi \in \text{Ass}_{X/S}(\mathcal{F})$ and let $Z = \overline{\{\xi\}}$. Picture

$$\begin{array}{ccc} \xi & & Z \longrightarrow X \\ \downarrow & & \searrow \downarrow f \\ f(\xi) & & S \end{array}$$

Note that $f(Z) \subset \overline{\{f(\xi)\}}$ and that $f(Z)$ is closed if and only if equality holds, i.e., $f(Z) = \overline{\{f(\xi)\}}$. It follows from Lemma 37.13.1 that if S, X are affine, the fibres X_s are Noetherian, \mathcal{F} is of finite type, and $\Gamma(X, \mathcal{F})$ is a projective $\Gamma(S, \mathcal{O}_S)$ -module, then $f(Z) = \overline{\{f(\xi)\}}$ is a closed subset. Slightly different analogous statements holds for the cases described in Lemmas 37.13.2, 37.13.3, and 37.13.4.

37.14. Impurities

We want to formalize the phenomenon of which we gave examples in Section 37.13 in terms of specializations of points of $\text{Ass}_{X/S}(\mathcal{F})$. We also want to work locally around a point $s \in S$. In order to do so we make the following definitions.

Situation 37.14.1. Here S, X are schemes and $f : X \rightarrow S$ is a finite type morphism. Also, \mathcal{F} is a finite type quasi-coherent \mathcal{O}_X -module. Finally s is a point of S .

In this situation consider a morphism $g : T \rightarrow S$, a point $t \in T$ with $g(t) = s$, a specialization $t' \rightsquigarrow t$, and a point $\xi \in X_{T'}$ in the base change of X lying over t' . Picture

$$(37.14.1.1) \quad \begin{array}{ccc} \xi & & X_{T'} \longrightarrow X \\ \downarrow & & \downarrow \quad \downarrow \\ t' & \rightsquigarrow & T \xrightarrow{g} S \\ & & \downarrow g \\ & & s \quad S \end{array}$$

Moreover, denote $\mathcal{F}_{T'}$ the pullback of \mathcal{F} to $X_{T'}$.

Definition 37.14.2. In Situation 37.14.1 we say a diagram (37.14.1.1) defines an *impurity of \mathcal{F} above s* if $\xi \in \text{Ass}_{X_{T'}/T'}(\mathcal{F}_{T'})$ and $\overline{\{\xi\}} \cap X_t = \emptyset$. We will indicate this by saying “let $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ be an impurity of \mathcal{F} above s ”.

Lemma 37.14.3. *In Situation 37.14.1. If there exists an impurity of \mathcal{F} above s , then there exists an impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s such that g is locally of finite presentation and t a closed point of the fibre of g above s .*

Proof. Let $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ be any impurity of \mathcal{F} above s . We apply Limits, Lemma 31.13.1 to $t \in T$ and $Z = \overline{\{\xi\}}$ to obtain an open neighbourhood $V \subset T'$ of t' , a commutative diagram

$$\begin{array}{ccc} V & \xrightarrow{a} & T' \\ \downarrow & & \downarrow b \\ T & \xrightarrow{g} & S \end{array}$$

and a closed subscheme $Z' \subset X_{T'}$ such that

- (1) the morphism $b : T' \rightarrow S$ is locally of finite presentation,
- (2) we have $Z' \cap X_{a(t)} = \emptyset$, and
- (3) $Z \cap X_V$ maps into Z' via the morphism $X_V \rightarrow X_{T'}$.

As t' specializes to t we may replace T by the open neighbourhood V of t' . Thus we have a commutative diagram

$$\begin{array}{ccccc} X_T & \longrightarrow & X_{T'} & \longrightarrow & X \\ \downarrow & & \downarrow & & \downarrow \\ T & \xrightarrow{a} & T' & \xrightarrow{b} & S \end{array}$$

where $b \circ a = g$. Let $\xi' \in X_{T'}$ denote the image of ξ . By Divisors, Lemma 30.7.2 we see that $\xi' \in \text{Ass}_{X_{T'}/T'}(\mathcal{F}_{T'})$. Moreover, by construction the closure of $\overline{\{\xi'\}}$ is

contained in the closed subset Z' which avoids the fibre $X_{a(t)}$. In this way we see that $(T' \rightarrow S, a(t') \rightsquigarrow a(t), \xi')$ is an impurity of \mathcal{F} above s .

Thus we may assume that $g : T \rightarrow S$ is locally of finite presentation. Let $Z = \overline{\{\xi\}}$. By assumption $Z_t = \emptyset$. By More on Morphisms, Lemma 36.19.1 this means that $Z_{t''} = \emptyset$ for t'' in an open subset of $\overline{\{t\}}$. Since the fibre of $T \rightarrow S$ over s is a Jacobson scheme, see Morphisms, Lemma 28.17.10 we find that there exist a closed point $t'' \in \overline{\{t\}}$ such that $Z_{t''} = \emptyset$. Then $(g : T \rightarrow S, t' \rightsquigarrow t'', \xi)$ is the desired impurity. \square

Lemma 37.14.4. *In Situation 37.14.1. Let $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ be an impurity of \mathcal{F} above s . Assume S is affine and that T is written $T = \lim_{i \in I} T_i$ as a directed colimit of affine schemes over S . Then for some i the triple $(T_i \rightarrow S, t'_i \rightsquigarrow t_i, \xi_i)$ is an impurity of \mathcal{F} above s .*

Proof. The notation in the statement means this: Let $f_i : T \rightarrow T_i$ be the projection morphisms, let $t_i = f_i(t)$ and $t'_i = f_i(t')$. Finally $\xi_i \in X_{T_i}$ is the image of ξ . By Divisors, Lemma 30.7.2 it is true that ξ_i is a point of the relative assassin of $\overline{\mathcal{F}_{T_i}}$ over T_i . Thus the only point is to show that $\overline{\{\xi_i\}} \cap X_{t_i} = \emptyset$ for some i . Set $Z = \overline{\{\xi\}}$. Apply Limits, Lemma 31.13.1 to this situation to obtain an open neighbourhood $V \subset T$ of t , a commutative diagram

$$\begin{array}{ccc} V & \xrightarrow{a} & T' \\ \downarrow & & \downarrow b \\ T & \xrightarrow{g} & S, \end{array}$$

and a closed subscheme $Z' \subset X_{T'}$ such that

- (1) the morphism $b : T' \rightarrow S$ is locally of finite presentation,
- (2) we have $Z' \cap X_{a(t)} = \emptyset$, and
- (3) $Z \cap X_V$ maps into Z' via the morphism $X_V \rightarrow X_{T'}$.

We may assume V is an affine open of T , hence by Limits, Lemmas 31.3.8 and 31.3.10 we can find an i and an affine open $V_i \subset T_i$ with $V = f_i^{-1}(V_i)$. By Limits, Proposition 31.5.1 after possibly increasing i a bit we can find a morphism $a_i : V_i \rightarrow T'$ such that $a = a_i \circ f_i|_V$. The induced morphism $X_{T_i} \rightarrow X_{T'}$ maps ξ_i into Z' . As $Z' \cap X_{a(t)} = \emptyset$ we conclude that $(T_i \rightarrow S, t'_i \rightsquigarrow t_i, \xi_i)$ is an impurity of \mathcal{F} above s . \square

Lemma 37.14.5. *In Situation 37.14.1. If there exists an impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s with g quasi-finite at t , then there exists an impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ such that $(T, t) \rightarrow (S, s)$ is an elementary étale neighbourhood.*

Proof. Let $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ be an impurity of \mathcal{F} above s such that g is quasi-finite at t . After shrinking T we may assume that g is locally of finite type. Apply More on Morphisms, Lemma 36.30.1 to $T \rightarrow S$ and $t \mapsto s$. This gives us a diagram

$$\begin{array}{ccccc} T & \longleftarrow & T \times_S U & \longleftarrow & V \\ \downarrow & & \downarrow & \swarrow & \\ S & \longleftarrow & U & & \end{array}$$

where $(U, u) \rightarrow (S, s)$ is an elementary étale neighbourhood and $V \subset T \times_S U$ is an open neighbourhood of $v = (t, u)$ such that $V \rightarrow U$ is finite and such that v is the unique point of V lying over u . Since the morphism $V \rightarrow T$ is étale hence flat we see that there exists a specialization $v' \rightsquigarrow v$ such that $v' \mapsto t'$. Note that $\kappa(t') \subset \kappa(v')$ is finite separable. Pick any point $\zeta \in X_{v'}$ mapping to $\xi \in X_{t'}$. By Divisors, Lemma 30.7.2 we see that $\zeta \in \text{Ass}_{X_{v'}/V}(\mathcal{F}_V)$. Moreover, the closure $\overline{\{\zeta\}}$ does not meet the fibre X_v as by assumption the closure $\overline{\{\xi\}}$ does not meet X_t . In other words $(V \rightarrow S, v' \rightsquigarrow v, \zeta)$ is an impurity of \mathcal{F} above S .

Next, let $u' \in U'$ be the image of v' and let $\theta \in X_U$ be the image of ζ . Then $\theta \mapsto u'$ and $u' \rightsquigarrow u$. By Divisors, Lemma 30.7.2 we see that $\theta \in \text{Ass}_{X_U/U}(\mathcal{F})$. Moreover, as $\pi : X_V \rightarrow X_U$ is finite we see that $\pi(\overline{\{\zeta\}}) = \overline{\{\pi(\zeta)\}}$. Since v is the unique point of V lying over u we see that $X_u \cap \overline{\{\pi(\zeta)\}} = \emptyset$ because $X_v \cap \overline{\{\zeta\}} = \emptyset$. In this way we conclude that $(U \rightarrow S, u' \rightsquigarrow u, \theta)$ is an impurity of \mathcal{F} above s and we win. \square

Lemma 37.14.6. *In Situation 37.14.1. Assume that S is locally Noetherian. If there exists an impurity of \mathcal{F} above s , then there exists an impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s such that g is quasi-finite at t .*

Proof. We may replace S by an affine neighbourhood of s . By Lemma 37.14.3 we may assume that we have an impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ of such that g is locally of finite type and t a closed point of the fibre of g above s . We may replace T by the reduced induced scheme structure on $\overline{\{t'\}}$. Let $Z = \overline{\{\xi\}} \subset X_T$. By assumption $Z_t = \emptyset$ and the image of $Z \rightarrow T$ contains t' . By More on Morphisms, Lemma 36.20.1 there exists a nonempty open $V \subset Z$ such that for any $w \in f(V)$ any generic point ξ' of V_w is in $\text{Ass}_{X_T/T}(\mathcal{F}_T)$. By More on Morphisms, Lemma 36.19.2 there exists a nonempty open $W \subset T$ with $W \subset f(V)$. By More on Morphisms, Lemma 36.35.7 there exists a closed subscheme $T' \subset T$ such that $t \in T'$, $T' \rightarrow S$ is quasi-finite at t , and there exists a point $z \in T' \cap W$, $z \rightsquigarrow t$ which does not map to s . Choose any generic point ξ' of the nonempty scheme V_z . Then $(T' \rightarrow S, z \rightsquigarrow t, \xi')$ is the desired impurity. \square

In the following we will use the henselization $S^h = \text{Spec}(\mathcal{O}_{S,s}^h)$ of S at s , see Étale Cohomology, Definition 44.33.2. Since $S^h \rightarrow S$ maps to closed point of S^h to s and induces an isomorphism of residue fields, we will indicate $s \in S^h$ this closed point also. Thus $(S^h, s) \rightarrow (S, s)$ is a morphism of pointed schemes.

Lemma 37.14.7. *In Situation 37.14.1. If there exists an impurity $(S^h \rightarrow S, s' \rightsquigarrow s, \xi)$ of \mathcal{F} above s then there exists an impurity $(T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s where $(T, t) \rightarrow (S, s)$ is an elementary étale neighbourhood.*

Proof. We may replace S by an affine neighbourhood of s . Say $S = \text{Spec}(A)$ and s corresponds to the prime $\mathfrak{p} \subset A$. Then $\mathcal{O}_{S,s}^h = \text{colim}_{(T,t)} \Gamma(T, \mathcal{O}_T)$ where the limit is over the opposite of the cofiltered category of affine elementary étale neighbourhoods (T, t) of (S, s) , see More on Morphisms, Lemma 36.27.5 and its proof. Hence $S^h = \lim_i T_i$ and we win by Lemma 37.14.4. \square

Lemma 37.14.8. *In Situation 37.14.1 the following are equivalent*

- (1) *there exists an impurity $(S^h \rightarrow S, s' \rightsquigarrow s, \xi)$ of \mathcal{F} above s where S^h is the henselization of S at s ,*

- (2) there exists an impurity $(T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s such that $(T, t) \rightarrow (S, s)$ is an elementary étale neighbourhood, and
- (3) there exists an impurity $(T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s such that $T \rightarrow S$ is quasi-finite at t .

Proof. As an étale morphism is locally quasi-finite it is clear that (2) implies (3). We have seen that (3) implies (2) in Lemma 37.14.5. We have seen that (1) implies (2) in Lemma 37.14.7. Finally, if $(T \rightarrow S, t' \rightsquigarrow t, \xi)$ is an impurity of \mathcal{F} above s such that $(T, t) \rightarrow (S, s)$ is an elementary étale neighbourhood, then we can choose a factorization $S^h \rightarrow T \rightarrow S$ of the structure morphism $S^h \rightarrow S$. Choose any point $s' \in S^h$ mapping to t' and choose any $\xi' \in X_{s'}$ mapping to $\xi \in X_{t'}$. Then $(S^h \rightarrow S, s' \rightsquigarrow s, \xi')$ is an impurity of \mathcal{F} above s . We omit the details. \square

37.15. Relatively pure modules

The notion of a module pure relative to a base was introduced in [GR71].

Definition 37.15.1. Let $f : X \rightarrow S$ be a morphism of schemes which is of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module.

- (1) Let $s \in S$. We say \mathcal{F} is *pure along* X_s if there is no impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ of \mathcal{F} above s with $(T, t) \rightarrow (S, s)$ an elementary étale neighbourhood.
- (2) We say \mathcal{F} is *universally pure along* X_s if there does not exist any impurity of \mathcal{F} above s .
- (3) We say that X is *pure along* X_s if \mathcal{O}_X is pure along X_s .
- (4) We say \mathcal{F} is *universally S -pure*, or *universally pure relative to* S if \mathcal{F} is universally pure along X_s for every $s \in S$.
- (5) We say \mathcal{F} is *S -pure*, or *pure relative to* S if \mathcal{F} is pure along X_s for every $s \in S$.
- (6) We say that X is *S -pure* or *pure relative to* S if \mathcal{O}_X is pure relative to S .

We intentionally restrict ourselves here to morphisms which are of finite type and not just morphisms which are locally of finite type, see Remark 37.15.2 for a discussion. In the situation of the definition Lemma 37.14.8 tells us that the following are equivalent

- (1) \mathcal{F} is pure along X_s ,
- (2) there is no impurity $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ with g quasi-finite at t ,
- (3) there does not exist any impurity of the form $(S^h \rightarrow S, s' \rightsquigarrow s, \xi)$, where S^h is the henselization of S at s .

If we denote $X^h = X \times_S S^h$ and \mathcal{F}^h the pullback of \mathcal{F} to X^h , then we can formulate the last condition in the following more positive way:

- (4) All points of $\text{Ass}_{X^h/S^h}(\mathcal{F}^h)$ specialize to points of X_s .

In particular, it is clear that \mathcal{F} is pure along X_s if and only if the pullback of \mathcal{F} to $X \times_S \text{Spec}(\mathcal{O}_{S,s})$ is pure along X_s .

Remark 37.15.2. Let $f : X \rightarrow S$ be a morphism which is locally of finite type and \mathcal{F} a quasi-coherent finite type \mathcal{O}_X -module. In this case it is still true that (1) and (2) above are equivalent because the proof of Lemma 37.14.5 does not use that f is quasi-compact. It is also clear that (3) and (4) are equivalent. However, we don't know if (1) and (3) are equivalent. In this case it may sometimes be more

convenient to define purity using the equivalent conditions (3) and (4) as is done in [GR71]. On the other hand, for many applications it seems that the correct notion is really that of being universally pure.

A natural question to ask is if the property of being pure relative to the base is preserved by base change, i.e., if being pure is the same thing as being universally pure. It turns out that this is true over Noetherian base schemes (see Lemma 37.15.5), or if the sheaf is flat (see Lemmas 37.17.3 and 37.17.4). It is not true in general, even if the morphism and the sheaf are of finite presentation, see Examples, Section 82.32 for a counter example. First we match our usage of “universally” to the usual notion.

Lemma 37.15.3. *Let $f : X \rightarrow S$ be a morphism of schemes which is of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Let $s \in S$. The following are equivalent*

- (1) \mathcal{F} is universally pure along X_s , and
- (2) for every morphism of pointed schemes $(S', s') \rightarrow (S, s)$ the pullback $\mathcal{F}_{S'}$ is pure along $X_{s'}$.

In particular, \mathcal{F} is universally pure relative to S if and only if every base change $\mathcal{F}_{S'}$ of \mathcal{F} is pure relative to S' .

Proof. This is formal. □

Lemma 37.15.4. *Let $f : X \rightarrow S$ be a morphism of schemes which is of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Let $s \in S$. Let $(S', s') \rightarrow (S, s)$ be a morphism of pointed schemes. If $S' \rightarrow S$ is quasi-finite at s' and \mathcal{F} is pure along X_s , then $\mathcal{F}_{S'}$ is pure along $X_{s'}$.*

Proof. It $(T \rightarrow S', t' \rightsquigarrow t, \xi)$ is an impurity of $\mathcal{F}_{S'}$ above s' with $T \rightarrow S'$ quasi-finite at t , then $(T \rightarrow S, t' \rightarrow t, \xi)$ is an impurity of \mathcal{F} above s with $T \rightarrow S$ quasi-finite at t , see Morphisms, Lemma 28.21.12. Hence the lemma follows immediately from the characterization (2) of purity given following Definition 37.15.1. □

Lemma 37.15.5. *Let $f : X \rightarrow S$ be a morphism of schemes which is of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Let $s \in S$. If $\mathcal{O}_{S,s}$ is Noetherian then \mathcal{F} is pure along X_s if and only if \mathcal{F} is universally pure along X_s .*

Proof. First we may replace S by $\text{Spec}(\mathcal{O}_{S,s})$, i.e., we may assume that S is Noetherian. Next, use Lemma 37.14.6 and characterization (2) of purity given in discussion following Definition 37.15.1 to conclude. □

Purity satisfies flat descent.

Lemma 37.15.6. *Let $f : X \rightarrow S$ be a morphism of schemes which is of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Let $s \in S$. Let $(S', s') \rightarrow (S, s)$ be a morphism of pointed schemes. Assume $S' \rightarrow S$ is flat at s' .*

- (1) If $\mathcal{F}_{S'}$ is pure along $X_{s'}$, then \mathcal{F} is pure along X_s .
- (2) If $\mathcal{F}_{S'}$ is universally pure along $X_{s'}$, then \mathcal{F} is universally pure along X_s .

Proof. Let $(T \rightarrow S, t' \rightsquigarrow t, \xi)$ be an impurity of \mathcal{F} above s . Set $T_1 = T \times_S S'$, and let t_1 be the unique point of T_1 mapping to t and s' . Since $T_1 \rightarrow T$ is flat at t_1 , see Morphisms, Lemma 28.26.7, there exists a specialization $t'_1 \rightsquigarrow t_1$ lying over $t' \rightsquigarrow t$, see Algebra, Section 10.40. Choose a point $\xi_1 \in X_{t'_1}$ which corresponds to a

generic point of $\text{Spec}(\kappa(t'_1) \otimes_{\kappa(t')} \kappa(\xi))$, see Schemes, Lemma 25.17.5. By Divisors, Lemma 30.7.2 we see that $\xi_1 \in \text{Ass}_{X_{T_1}/T_1}(\mathcal{F}_{T_1})$. As the Zariski closure of $\{\xi_1\}$ in X_{T_1} maps into the Zariski closure of $\{\xi\}$ in X_T we conclude that this closure is disjoint from X_{t_1} . Hence $(T_1 \rightarrow S', t'_1 \rightsquigarrow t_1, \xi_1)$ is an impurity of $\mathcal{F}_{S'}$ above s' . In other words we have proved the contrapositive to part (2) of the lemma. Finally, if $(T, t) \rightarrow (S, s)$ is an elementary étale neighbourhood, then $(T_1, t_1) \rightarrow (S', s')$ is an elementary étale neighbourhood too, and in this way we see that (1) holds. \square

Lemma 37.15.7. *Let $i : Z \rightarrow X$ be a closed immersion of schemes of finite type over a scheme S . Let $s \in S$. Let \mathcal{F} be a finite type, quasi-coherent sheaf on Z . Then \mathcal{F} is (universally) pure along Z_s if and only if $i_*\mathcal{F}$ is (universally) pure along X_s .*

Proof. Omitted. \square

37.16. Examples of relatively pure sheaves

Here are some example cases where it is possible to see what purity means.

Lemma 37.16.1. *Let $f : X \rightarrow S$ be a proper morphism of schemes. Then every finite type, quasi-coherent \mathcal{O}_X -module \mathcal{F} is universally pure relative to S . In particular X is universally pure relative to S .*

Proof. Let $(g : T \rightarrow S, t' \rightsquigarrow t, \xi)$ be an impurity of \mathcal{F} above $s \in S$. Since f is proper, it is universally closed. Hence $f_T : X_T \rightarrow T$ is closed. Since $f_T(\xi) = t'$ this implies that $t \in f(\{\xi\})$ which is a contradiction. \square

Lemma 37.16.2. *Let $f : X \rightarrow S$ be a separated, finite type morphism of schemes. Let \mathcal{F} be a finite type, quasi-coherent \mathcal{O}_X -module. Assume that $\text{Supp}(\mathcal{F}_s)$ is finite for every $s \in S$. Then the following are equivalent*

- (1) \mathcal{F} is pure relative to S ,
- (2) the scheme theoretic support of \mathcal{F} is finite over S , and
- (3) \mathcal{F} is universally pure relative to S .

In particular, given a quasi-finite separated morphism $X \rightarrow S$ we see that X is pure relative to S if and only if $X \rightarrow S$ is finite.

Proof. Let $Z \subset X$ be the scheme theoretic support of \mathcal{F} , see Morphisms, Definition 28.5.5. Then $Z \rightarrow S$ is a separated, finite type morphism of schemes with finite fibres. Hence it is separated and quasi-finite, see Morphisms, Lemma 28.21.10. By Lemma 37.15.7 it suffices to prove the lemma for $Z \rightarrow S$ and the sheaf \mathcal{F} viewed as a finite type quasi-coherent module on Z . Hence we may assume that $X \rightarrow S$ is separated and quasi-finite and that $\text{Supp}(\mathcal{F}) = X$.

It follows from Lemma 37.16.1 and Morphisms, Lemma 28.44.10 that (2) implies (3). Trivially (3) implies (1). Assume (1) holds. We will prove that (2) holds. It is clear that we may assume S is affine. By More on Morphisms, Lemma 36.31.3 we can find a diagram

$$\begin{array}{ccc}
 X & \xrightarrow{\quad j \quad} & T \\
 & \searrow f & \swarrow \pi \\
 & & S
 \end{array}$$

with π finite and j a quasi-compact open immersion. If we show that j is closed, then j is a closed immersion and we conclude that $f = \pi \circ j$ is finite. To show that j is closed it suffices to show that specializations lift along j , see Schemes, Lemma 25.19.8. Let $x \in X$, set $t' = j(x)$ and let $t' \rightsquigarrow t$ be a specialization. We have to show $t \in j(X)$. Set $s' = f(x)$ and $s = \pi(t)$ so $s' \rightsquigarrow s$. By More on Morphisms, Lemma 36.30.4 we can find an elementary étale neighbourhood $(U, u) \rightarrow (S, s)$ and a decomposition

$$T_U = T \times_S U = V \amalg W$$

into open and closed subschemes, such that $V \rightarrow U$ is finite and there exists a unique point v of V mapping to u , and such that v maps to t' in T . As $V \rightarrow T$ is étale, we can lift generalizations, see Morphisms, Lemmas 28.26.8 and 28.37.12. Hence there exists a specialization $v' \rightsquigarrow v$ such that v' maps to $t' \in T$. In particular we see that $v' \in X_U \subset T_U$. Denote $u' \in U$ the image of t' . Note that $v' \in \text{Ass}_{X_U/U}(\mathcal{F})$ because $X_{u'}$ is a finite discrete set and $X_{u'} = \text{Supp}(\mathcal{F}_{u'})$. As \mathcal{F} is pure relative to S we see that v' must specialize to a point in $X_{u'}$. Since v is the only point of V lying over u (and since no point of W can be a specialization of v') we see that $v \in X_u$. Hence $t \in X$. \square

Lemma 37.16.3. *Let $f : X \rightarrow S$ be a finite type, flat morphism of schemes with geometrically integral fibres. Then X is universally pure over S .*

Proof. Let $\xi \in X$ with $s' = f(\xi)$ and $s' \rightsquigarrow s$ a specialization of S . If ξ is an associated point of $X_{s'}$, then ξ is the unique generic point because $X_{s'}$ is an integral scheme. Let ξ_0 be the unique generic point of X_s . As $X \rightarrow S$ is flat we can lift $s' \rightsquigarrow s$ to a specialization $\xi' \rightsquigarrow \xi_0$ in X , see Morphisms, Lemma 28.26.8. The $\xi \rightsquigarrow \xi'$ because ξ is the generic point of $X_{s'}$ hence $\xi \rightsquigarrow \xi_0$. This means that $(\text{id}_S, s' \rightarrow s, \xi)$ is not an impurity of \mathcal{O}_X above s . Since the assumption that f is finite type, flat with geometrically integral fibres is preserved under base change, we see that there doesn't exist an impurity after any base change. In this way we see that X is universally S -pure. \square

Lemma 37.16.4. *Let $f : X \rightarrow S$ be a finite type, affine morphism of schemes. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module such that $f_*\mathcal{F}$ is locally projective on S , see Properties, Definition 27.19.1. Then \mathcal{F} is universally pure over S .*

Proof. After reducing to the case where S is the spectrum of a henselian local ring this follows from Lemma 37.13.1. \square

37.17. A criterion for purity

We first prove that given a flat family of finite type quasi-coherent sheaves the points in the relative assassin specialize to points in the relative assassins of nearby fibres (if they specialize at all).

Lemma 37.17.1. *Let $f : X \rightarrow S$ be a morphism of schemes of finite type. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. Let $s \in S$. Assume that \mathcal{F} is flat over S at all points of X_s . Let $x' \in \text{Ass}_{X/S}(\mathcal{F})$ with $f(x') = s'$ such that $s' \rightsquigarrow s$ is a specialization in S . If x' specializes to a point of $X_{s'}$, then $x' \rightsquigarrow x$ with $x \in \text{Ass}_{X_s}(\mathcal{F}_s)$.*

Proof. Let $x' \rightsquigarrow t$ be a specialization with $t \in X_{s'}$. We may replace X by an affine neighbourhood of t and S by an affine neighbourhood of s . Choose a closed

immersion $i : X \rightarrow \mathbf{A}_S^n$. Then it suffices to prove the lemma for the module $i_*\mathcal{F}$ on \mathbf{A}_S^n and the point $i(x')$. Hence we may assume $X \rightarrow S$ is of finite presentation.

Let $x' \rightsquigarrow t$ be a specialization with $t \in X_s$. Set $A = \mathcal{O}_{S,s}$, $B = \mathcal{O}_{X,t}$, and $N = \mathcal{F}_t$. Note that B is essentially of finite presentation over A and that N is a finite B -module flat over A . Also N is a finitely presented B -module by Lemma 37.10.9. Let $\mathfrak{q}' \subset B$ be the prime ideal corresponding to x' and let $\mathfrak{p}' \subset A$ be the prime ideal corresponding to s' . The assumption $x' \in \text{Ass}_{X/S}(\mathcal{F})$ means that \mathfrak{q}' is an associated prime of $N \otimes_A \kappa(\mathfrak{p}')$. Let $\Sigma \subset B$ be the multiplicative subset of elements which are not zerodivisors on $N/\mathfrak{m}_A N$. By Lemma 37.7.2 the map $N \rightarrow \Sigma^{-1}N$ is universally injective. In particular, we see that $N \otimes_A \kappa(\mathfrak{p}') \rightarrow \Sigma^{-1}N \otimes_A \kappa(\mathfrak{p}')$ is injective which implies that \mathfrak{q}' is an associated prime of $\Sigma^{-1}N \otimes_A \kappa(\mathfrak{p}')$ and hence \mathfrak{q}' is in the image of $\text{Spec}(\Sigma^{-1}B) \rightarrow \text{Spec}(B)$. Thus Lemma 37.7.1 implies that $\mathfrak{q}' \subset \mathfrak{q}$ for some prime $\mathfrak{q} \in \text{Ass}_B(N/\mathfrak{m}_A N)$ (which in particular implies that $\mathfrak{m}_A = A \cap \mathfrak{q}$). If $x \in X_s$ denotes the point corresponding to \mathfrak{q} , then $x \in \text{Ass}_{X_s}(\mathcal{F}_s)$ and $x' \rightsquigarrow x$ as desired. \square

Lemma 37.17.2. *Let $f : X \rightarrow S$ be a morphism of schemes of finite type. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. Let $s \in S$. Let $(S', s') \rightarrow (S, s)$ be an elementary étale neighbourhood and let*

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & S' \end{array}$$

be a commutative diagram of morphisms of schemes. Assume

- (1) \mathcal{F} is flat over S at all points of X_s ,
- (2) $X' \rightarrow S'$ is of finite type,
- (3) $g^*\mathcal{F}$ is pure along X'_s ,
- (4) $g : X' \rightarrow X$ is étale, and
- (5) $g(X')$ contains $\text{Ass}_{X_s}(\mathcal{F}_s)$.

In this situation \mathcal{F} is pure along X_s if and only if the image of $X' \rightarrow X \times_S S'$ contains the points of $\text{Ass}_{X \times_S S'/S'}(\mathcal{F} \times_S S')$ lying over points in S' which specialize to s' .

Proof. Since the morphism $S' \rightarrow S$ is étale, we see that if \mathcal{F} is pure along X_s , then $\mathcal{F} \times_S S'$ is pure along X_s , see Lemma 37.15.4. Since purity satisfies flat descent, see Lemma 37.15.6, we see that if $\mathcal{F} \times_S S'$ is pure along $X_{s'}$, then \mathcal{F} is pure along X_s . Hence we may replace S by S' and assume that $S = S'$ so that $g : X' \rightarrow X$ is an étale morphism between schemes of finite type over S . Moreover, we may replace S by $\text{Spec}(\mathcal{O}_{S,s})$ and assume that S is local.

First, assume that \mathcal{F} is pure along X_s . In this case every point of $\text{Ass}_{X/S}(\mathcal{F})$ specializes to a point of X_s by purity. Hence by Lemma 37.17.1 we see that every point of $\text{Ass}_{X/S}(\mathcal{F})$ specializes to a point of $\text{Ass}_{X_s}(\mathcal{F}_s)$. Thus every point of $\text{Ass}_{X/S}(\mathcal{F})$ is in the image of g (as the image is open and contains $\text{Ass}_{X_s}(\mathcal{F}_s)$).

Conversely, assume that $g(X')$ contains $\text{Ass}_{X/S}(\mathcal{F})$. Let $S^h = \text{Spec}(\mathcal{O}_{S,s}^h)$ be the henselization of S at s . Denote $g^h : (X')^h \rightarrow X^h$ the base change of g by $S^h \rightarrow S$, and denote \mathcal{F}^h the pullback of \mathcal{F} to X^h . By Divisors, Lemma 30.7.2 and Remark 30.7.3 the relative assassin $\text{Ass}_{X^h/S^h}(\mathcal{F}^h)$ is the inverse image of $\text{Ass}_{X/S}(\mathcal{F})$ via

the projection $X^h \rightarrow X$. As we have assumed that $g(X')$ contains $\text{Ass}_{X/S}(\mathcal{F})$ we conclude that the base change $g^h((X')^h) = g(X') \times_S S^h$ contains $\text{Ass}_{X^h/S^h}(\mathcal{F}^h)$. In this way we reduce to the case where S is the spectrum of a henselian local ring. Let $x \in \text{Ass}_{X/S}(\mathcal{F})$. To finish the proof of the lemma we have to show that x specializes to a point of X_s , see criterion (4) for purity in discussion following Definition 37.15.1. By assumption there exists a $x' \in X'$ such that $g(x') = x$. As $g : X' \rightarrow X$ is étale, we see that $x' \in \text{Ass}_{X'/S}(g^*\mathcal{F})$, see Lemma 37.2.7 (applied to the morphism of fibres $X'_w \rightarrow X_w$ where $w \in S$ is the image of x'). Since $g^*\mathcal{F}$ is pure along X'_s we see that $x' \rightsquigarrow y$ for some $y \in X'_s$. Hence $x = g(x') \rightsquigarrow g(y)$ and $g(y) \in X_s$ as desired. \square

Lemma 37.17.3. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. Let $s \in S$. Assume*

- (1) f is of finite type,
- (2) \mathcal{F} is of finite type,
- (3) \mathcal{F} is flat over S at all points of X_s , and
- (4) \mathcal{F} is pure along X_s .

Then \mathcal{F} is universally pure along X_s .

Proof. We first make a preliminary remark. Suppose that $(S', s') \rightarrow (S, s)$ is an elementary étale neighbourhood. Denote \mathcal{F}' the pullback of \mathcal{F} to $X' = X \times_S S'$. By the discussion following Definition 37.15.1 we see that \mathcal{F}' is pure along $X'_{s'}$. Moreover, \mathcal{F}' is flat over S' along $X'_{s'}$. Then it suffices to prove that \mathcal{F}' is universally pure along $X'_{s'}$. Namely, given any morphism $(T, t) \rightarrow (S, s)$ of pointed schemes the fibre product $(T', t') = (T \times_S S', (t, s'))$ is flat over (T, t) and hence if $\mathcal{F}_{T'}$ is pure along $X_{t'}$ then \mathcal{F}_T is pure along X_t by Lemma 37.15.6. Thus during the proof we may always replace (s, S) by an elementary étale neighbourhood. We may also replace S by $\text{Spec}(\mathcal{O}_{S,s})$ due to the local nature of the problem.

Choose an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & \text{Spec}(\mathcal{O}_{S',s'}) \end{array}$$

such that $X' \rightarrow X \times_S \text{Spec}(\mathcal{O}_{S',s'})$ is étale, $X_s = g((X')_{s'})$, the scheme X' is affine, and such that $\Gamma(X', g^*\mathcal{F})$ is a free $\mathcal{O}_{S',s'}$ -module, see Lemma 37.11.11. Note that $X' \rightarrow \text{Spec}(\mathcal{O}_{S',s'})$ is of finite type (as a quasi-compact morphism which is the composition of an étale morphism and the base change of a finite type morphism). By our preliminary remarks in the first paragraph of the proof we may replace S by $\text{Spec}(\mathcal{O}_{S',s'})$. Hence we may assume there exists a commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ & \searrow & \swarrow \\ & S & \end{array}$$

of schemes of finite type over S , where g is étale, $X_s \subset g(X')$, with S local with closed point s , with X' affine, and with $\Gamma(X', g^*\mathcal{F})$ a free $\Gamma(S, \mathcal{O}_S)$ -module. Note that in this case $g^*\mathcal{F}$ is universally pure over S , see Lemma 37.16.4.

In this situation we apply Lemma 37.17.2 to deduce that $\text{Ass}_{X/S}(\mathcal{F}) \subset g(X')$ from our assumption that \mathcal{F} is pure along X_s and flat over S along X_s . By Divisors, Lemma 30.7.2 and Remark 30.7.3 we see that for any morphism of pointed schemes $(T, t) \rightarrow (S, s)$ we have

$$\text{Ass}_{X_T/T}(\mathcal{F}_T) \subset (X_T \rightarrow X)^{-1}(\text{Ass}_{X/S}(\mathcal{F})) \subset g(X') \times_S T = g_T(X'_T).$$

Hence by Lemma 37.17.2 applied to the base change of our displayed diagram to (T, t) we conclude that \mathcal{F}_T is pure along X_t as desired. \square

Lemma 37.17.4. *Let $f : X \rightarrow S$ be a finite type morphism of schemes. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Assume \mathcal{F} is flat over S . In this case \mathcal{F} is pure relative to S if and only if \mathcal{F} is universally pure relative to S .*

Proof. Immediate consequence of Lemma 37.17.3 and the definitions. \square

Lemma 37.17.5. *Let I be a directed partially ordered set. Let $(S_i, g_{ii'})$ be an inverse system of affine schemes over I . Set $S = \lim_i S_i$ and $s \in S$. Denote $g_i : S \rightarrow S_i$ the projections and set $s_i = g_i(s)$. Suppose that $f : X \rightarrow S$ is a morphism of finite presentation, \mathcal{F} a quasi-coherent \mathcal{O}_X -module of finite presentation which is pure along X_s and flat over S at all points of X_s . Then there exists an $i \in I$, a morphism of finite presentation $X_i \rightarrow S_i$, a quasi-coherent \mathcal{O}_{X_i} -module \mathcal{F}_i of finite presentation which is pure along $(X_i)_{s_i}$ and flat over S_i at all points of $(X_i)_{s_i}$ such that $X \cong X_i \times_{S_i} S$ and such that the pullback of \mathcal{F}_i to X is isomorphic to \mathcal{F} .*

Proof. Let $U \subset X$ be the set of points where \mathcal{F} is flat over S . By More on Morphisms, Theorem 36.12.1 this is an open subscheme of X . By assumption $X_s \subset U$. As X_s is quasi-compact, we can find a quasi-compact open $U' \subset U$ with $X_s \subset U'$. By Limits, Lemma 31.9.1 we can find an $i \in I$ and a morphism of finite presentation $f_i : X_i \rightarrow S_i$ whose base change to S is isomorphic to f . Fix such a choice and set $X_{i'} = X_i \times_{S_i} S_{i'}$. Then $X = \lim_{i'} X_{i'}$ with affine transition morphisms. By Limits, Lemma 31.9.2 we can, after possible increasing i assume there exists a quasi-coherent \mathcal{O}_{X_i} -module \mathcal{F}_i of finite presentation whose base change to S is isomorphic to \mathcal{F} . By Limits, Lemma 31.3.8 after possibly increasing i we may assume there exists an open $U'_i \subset X_i$ whose inverse image in X is U' . Note that in particular $(X_i)_{s_i} \subset U'_i$. By Limits, Lemma 31.9.3 (after increasing i once more) we may assume that \mathcal{F}_i is flat on U'_i . In particular we see that \mathcal{F}_i is flat along $(X_i)_{s_i}$.

Next, we use Lemma 37.11.5 to choose an elementary étale neighbourhood $(S'_i, s'_i) \rightarrow (S_i, s_i)$ and a commutative diagram of schemes

$$\begin{array}{ccc} X_i & \xleftarrow{g_i} & X'_i \\ \downarrow & & \downarrow \\ S_i & \xleftarrow{\quad} & S'_i \end{array}$$

such that g_i is étale, $(X_i)_{s_i} \subset g_i(X'_i)$, the schemes X'_i, S'_i are affine, and such that $\Gamma(X'_i, g_i^* \mathcal{F}_i)$ is a projective $\Gamma(S'_i, \mathcal{O}_{S'_i})$ -module. Note that $g_i^* \mathcal{F}_i$ is universally pure over S'_i , see Lemma 37.16.4. We may base change the diagram above to a diagram with morphisms $(S'_{i'}, s'_{i'}) \rightarrow (S'_i, s'_i)$ and $g_{i'} : X'_{i'} \rightarrow X'_i$ over $S'_{i'}$ for any $i' \geq i$ and we may base change the diagram to a diagram with morphisms $(S', s') \rightarrow (S, s)$ and $g : X' \rightarrow X$ over S .

At this point we can use our criterion for purity. Set $W'_i \subset X_i \times_{S_i} S'_i$ equal to the image of the étale morphism $X'_i \rightarrow X_i \times_{S_i} S'_i$. For every $i' \geq i$ we have similarly the image $W'_{i'} \subset X_{i'} \times_{S_{i'}} S'_{i'}$ and we have the image $W' \subset X \times_S S'$. Taking images commutes with base change, hence $W'_{i'} = W'_i \times_{S'_i} S'_{i'}$ and $W' = W_i \times_{S_i} S'$. Because \mathcal{F} is pure along X_s the Lemma 37.17.2 implies that

$$(37.17.5.1) \quad f^{-1}(\text{Spec}(\mathcal{O}_{S',s'})) \cap \text{Ass}_{X \times_S S'/S'}(\mathcal{F} \times_S S') \subset W'$$

By More on Morphisms, Lemma 36.20.5 we see that

$$E = \{t \in S' \mid \text{Ass}_{X_t}(\mathcal{F}_t) \subset W'\} \quad \text{and} \quad E_{i'} = \{t \in S'_{i'} \mid \text{Ass}_{X_t}(\mathcal{F}_{i',t}) \subset W'_{i'}\}$$

are locally constructible subsets of S' and $S'_{i'}$. By More on Morphisms, Lemma 36.20.4 we see that $E_{i'}$ is the inverse image of E_i under the morphism $S'_{i'} \rightarrow S'_i$ and that E is the inverse image of E_i under the morphism $S' \rightarrow S'_i$. Thus Equation (37.17.5.1) is equivalent to the assertion that $\text{Spec}(\mathcal{O}_{S',s'})$ maps into E_i . As $\mathcal{O}_{S',s'} = \text{colim}_{i' \geq i} \mathcal{O}_{S'_{i'},s'_{i'}}$ we see that $\text{Spec}(\mathcal{O}_{S'_{i'},s'_{i'}})$ maps into E_i for some $i' \geq i$, see Limits, Lemma 31.3.7. Then, applying Lemma 37.17.2 to the situation over $S_{i'}$, we conclude that $\mathcal{F}_{i'}$ is pure along $(X_{i'})_{s_{i'}}$. \square

Lemma 37.17.6. *Let $f : X \rightarrow S$ be a morphism of finite presentation. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite presentation flat over S . Then the set*

$$U = \{s \in S \mid \mathcal{F} \text{ is pure along } X_s\}$$

is open in S .

Proof. Let $s \in U$. Using Lemma 37.11.5 we can find an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and a commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ \downarrow & & \downarrow \\ S & \xleftarrow{\quad} & S' \end{array}$$

such that g is étale, $X_s \subset g(X')$, the schemes X', S' are affine, and such that $\Gamma(X', g^*\mathcal{F})$ is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module. Note that $g^*\mathcal{F}$ is universally pure over S' , see Lemma 37.16.4. Set $W' \subset X \times_S S'$ equal to the image of the étale morphism $X' \rightarrow X \times_S S'$. Note that W' is open and quasi-compact over S' . Set

$$E = \{t \in S' \mid \text{Ass}_{X_t}(\mathcal{F}_t) \subset W'\}.$$

By More on Morphisms, Lemma 36.20.5 E is a constructible subset of S' . By Lemma 37.17.2 we see that $\text{Spec}(\mathcal{O}_{S',s'}) \subset E$. By Morphisms, Lemma 28.23.4 we see that E contains an open neighbourhood V' of s' . Applying Lemma 37.17.2 once more we see that for any point s_1 in the image of V' in S the sheaf \mathcal{F} is pure along X_{s_1} . Since $S' \rightarrow S$ is étale the image of V' in S is open and we win. \square

37.18. How purity is used

Here are some examples of how purity can be used. The first lemma actually uses a slightly weaker form of purity.

Lemma 37.18.1. *Let $f : X \rightarrow S$ be a morphism of finite type. Let \mathcal{F} be a quasi-coherent sheaf of finite type on X . Assume S is local with closed point s . Assume \mathcal{F} is pure along X_s and that \mathcal{F} is flat over S . Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ of quasi-coherent \mathcal{O}_X -modules. Then the following are equivalent*

- (1) the map on stalks φ_x is injective for all $x \in \text{Ass}_{X_s}(\mathcal{F}_s)$, and
- (2) φ is injective.

Proof. Let $\mathcal{K} = \text{Ker}(\varphi)$. Our goal is to prove that $\mathcal{K} = 0$. In order to do this it suffices to prove that $\text{WeakAss}_X(\mathcal{K}) = \emptyset$, see Divisors, Lemma 30.5.5. We have $\text{WeakAss}_X(\mathcal{K}) \subset \text{WeakAss}_X(\mathcal{F})$, see Divisors, Lemma 30.5.4. As \mathcal{F} is flat we see from Lemma 37.12.4 that $\text{WeakAss}_X(\mathcal{F}) \subset \text{Ass}_{X/S}(\mathcal{F})$. By purity any point x' of $\text{Ass}_{X/S}(\mathcal{F})$ is a generalization of a point of X_s , and hence is the specialization of a point $x \in \text{Ass}_{X_s}(\mathcal{F}_s)$, by Lemma 37.17.1. Hence the injectivity of φ_x implies the injectivity of $\varphi_{x'}$, whence $\mathcal{K}_{x'} = 0$. \square

Proposition 37.18.2. *Let $f : X \rightarrow S$ be an affine, finitely presented morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite presentation, flat over S . Then the following are equivalent*

- (1) $f_*\mathcal{F}$ is locally projective on S , and
- (2) \mathcal{F} is pure relative to S .

In particular, given a ring map $A \rightarrow B$ of finite presentation and a finitely presented B -module N flat over A we have: N is projective as an A -module if and only if \tilde{N} on $\text{Spec}(B)$ is pure relative to $\text{Spec}(A)$.

Proof. The implication (1) \Rightarrow (2) is Lemma 37.16.4. Assume \mathcal{F} is pure relative to S . Note that by Lemma 37.17.3 this implies \mathcal{F} remains pure after any base change. By Descent, Lemma 34.6.7 it suffices to prove $f_*\mathcal{F}$ is fpqc locally projective on S . Pick $s \in S$. We will prove that the restriction of $f_*\mathcal{F}$ to an étale neighbourhood of s is locally projective. Namely, by Lemma 37.11.5, after replacing S by an affine elementary étale neighbourhood of s , we may assume there exists a diagram

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ & \searrow & \swarrow \\ & S & \end{array}$$

of schemes affine and of finite presentation over S , where g is étale, $X_s \subset g(X')$, and with $\Gamma(X', g^*\mathcal{F})$ a projective $\Gamma(S, \mathcal{O}_S)$ -module. Note that in this case $g^*\mathcal{F}$ is universally pure over S , see Lemma 37.16.4. Hence by Lemma 37.17.2 we see that the open $g(X')$ contains the points of $\text{Ass}_{X/S}(\mathcal{F})$ lying over $\text{Spec}(\mathcal{O}_{S,s})$. Set

$$E = \{t \in S \mid \text{Ass}_{X_t}(\mathcal{F}_t) \subset g(X')\}.$$

By More on Morphisms, Lemma 36.20.5 E is a constructible subset of S . We have seen that $\text{Spec}(\mathcal{O}_{S,s}) \subset E$. By Morphisms, Lemma 28.23.4 we see that E contains an open neighbourhood of s . Hence after replacing S by an affine neighbourhood of s we may assume that $\text{Ass}_{X/S}(\mathcal{F}) \subset g(X')$. By Lemma 37.7.4 this means that

$$\Gamma(X, \mathcal{F}) \longrightarrow \Gamma(X', g^*\mathcal{F})$$

is $\Gamma(S, \mathcal{O}_S)$ -universally injective. By Algebra, Lemma 10.86.7 we conclude that $\Gamma(X, \mathcal{F})$ is Mittag-Leffler as an $\Gamma(S, \mathcal{O}_S)$ -module. Since $\Gamma(X, \mathcal{F})$ is countably generated and flat as a $\Gamma(S, \mathcal{O}_S)$ -module, we conclude it is projective by Algebra, Lemma 10.90.1. \square

We can use the proposition to improve some of our earlier results. The following lemma is an improvement of Proposition 37.11.4.

Lemma 37.18.3. *Let $f : X \rightarrow S$ be a morphism which is locally of finite presentation. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module which is of finite presentation. Let $x \in X$ with $s = f(x) \in S$. If \mathcal{F} is flat at x over S there exists an affine elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an affine open $U' \subset X \times_S S'$ which contains $x' = (x, s')$ such that $\Gamma(U', \mathcal{F}|_{U'})$ is a projective $\Gamma(S', \mathcal{O}_{S'})$ -module.*

Proof. During the proof we may replace X by an open neighbourhood of x and we may replace S by an elementary étale neighbourhood of s . Hence, by openness of flatness (see More on Morphisms, Theorem 36.12.1) we may assume that \mathcal{F} is flat over S . We may assume S and X are affine. After shrinking X some more we may assume that any point of $\text{Ass}_{X_s}(\mathcal{F}_s)$ is a generalization of x . This property is preserved on replacing (S, s) by an elementary étale neighbourhood. Hence we may apply Lemma 37.11.5 to arrive at the situation where there exists a diagram

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ & \searrow & \swarrow \\ & S & \end{array}$$

of schemes affine and of finite presentation over S , where g is étale, $X_s \subset g(X')$, and with $\Gamma(X', g^*\mathcal{F})$ a projective $\Gamma(S, \mathcal{O}_S)$ -module. Note that in this case $g^*\mathcal{F}$ is universally pure over S , see Lemma 37.16.4.

Let $U \subset g(X')$ be an affine open neighbourhood of x . We claim that $\mathcal{F}|_U$ is pure along U_s . If we prove this, then the lemma follows because $\mathcal{F}|_U$ will be pure relative to S after shrinking S , see Lemma 37.17.6, whereupon the projectivity follows from Proposition 37.18.2. To prove the claim we have to show, after replacing (S, s) by an arbitrary elementary étale neighbourhood, that any point ξ of $\text{Ass}_{U/S}(\mathcal{F}|_U)$ lying over some $s' \in S$, $s' \rightsquigarrow s$ specializes to a point of U_s . Since $U \subset g(X')$ we can find a $\xi' \in X'$ with $g(\xi') = \xi$. Because $g^*\mathcal{F}$ is pure over S , using Lemma 37.17.1, we see there exists a specialization $\xi' \rightsquigarrow x'$ with $x' \in \text{Ass}_{X'_s}(g^*\mathcal{F}_s)$. Then $g(x') \in \text{Ass}_{X_s}(\mathcal{F}_s)$ (see for example Lemma 37.2.7 applied to the étale morphism $X'_s \rightarrow X_s$ of Noetherian schemes) and hence $g(x') \rightsquigarrow x$ by our choice of X above! Since $x \in U$ we conclude that $g(x') \in U$. Thus $\xi = g(\xi') \rightsquigarrow g(x') \in U_s$ as desired. \square

The following lemma is an improvement of Lemma 37.11.9.

Lemma 37.18.4. *Let $f : X \rightarrow S$ be a morphism which is locally of finite type. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module which is of finite type. Let $x \in X$ with $s = f(x) \in S$. If \mathcal{F} is flat at x over S there exists an affine elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ and an affine open $U' \subset X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ which contains $x' = (x, s')$ such that $\Gamma(U', \mathcal{F}|_{U'})$ is a free $\mathcal{O}_{S', s'}$ -module.*

Proof. The question is Zariski local on X and S . Hence we may assume that X and S are affine. Then we can find a closed immersion $i : X \rightarrow \mathbf{A}_S^n$ over S . It is clear that it suffices to prove the lemma for the sheaf $i_*\mathcal{F}$ on \mathbf{A}_S^n and the point $i(x)$. In this way we reduce to the case where $X \rightarrow S$ is of finite presentation. After replacing S by $\text{Spec}(\mathcal{O}_{S', s'})$ and X by an open of $X \times_S \text{Spec}(\mathcal{O}_{S', s'})$ we may assume that \mathcal{F} is of finite presentation, see Proposition 37.10.3. In this case we may appeal to Lemma 37.18.3 and Algebra, Theorem 10.82.4 to conclude. \square

Lemma 37.18.5. *Let $A \rightarrow B$ be a local ring map of local rings which is essentially of finite type. Let N be a finite B -module which is flat as an A -module. If A is henselian, then N is a filtered colimit*

$$N = \operatorname{colim}_i F_i$$

of free A -modules F_i such that all transition maps $u_i : F_i \rightarrow F_{i'}$ of the system induce injective maps $\bar{u}_i : F_i/\mathfrak{m}_A F_i \rightarrow F_{i'}/\mathfrak{m}_A F_{i'}$. Also, N is a Mittag-Leffler A -module.

Proof. We can find a morphism of finite type $X \rightarrow S = \operatorname{Spec}(A)$ and a point $x \in X$ lying over the closed point s of S and a finite type quasi-coherent \mathcal{O}_X -module \mathcal{F} such that $\mathcal{F}_x \cong N$ as an A -module. After shrinking X we may assume that each point of $\operatorname{Ass}_{X_s}(\mathcal{F}_s)$ specializes to x . By Lemma 37.18.4 we see that there exists a fundamental system of affine open neighbourhoods $U_i \subset X$ of x such that $\Gamma(U_i, \mathcal{F})$ is a free A -module F_i . Note that if $U_{i'} \subset U_i$, then

$$F_i/\mathfrak{m}_A F_i = \Gamma(U_{i,s}, \mathcal{F}_s) \longrightarrow \Gamma(U_{i',s}, \mathcal{F}_s) = F_{i'}/\mathfrak{m}_A F_{i'}$$

is injective because a section of the kernel would be supported at a closed subset of X_s not meeting x which is a contradiction to our choice of X above. Since the maps $F_i \rightarrow F_{i'}$ are A -universally injective (Lemma 37.7.5) it follows that N is Mittag-Leffler by Algebra, Lemma 10.86.8. \square

The following lemma should be skipped if reading through for the first time.

Lemma 37.18.6. *Let $A \rightarrow B$ be a local ring map of local rings which is essentially of finite type. Let N be a finite B -module which is flat as an A -module. If A is a valuation ring, then any element of N has a content ideal $I \subset A$ (More on Algebra, Definition 15.16.1).*

Proof. Let $A \subset A^h$ be the henselization. Let B' be the localization of $B \otimes_A A^h$ at the maximal ideal $\mathfrak{m}_B \otimes A^h + B \otimes \mathfrak{m}_{A^h}$. Then $B \rightarrow B'$ is flat, hence faithfully flat. Let $N' = N \otimes_B B'$. Let $x \in N$ and let $x' \in N'$ be the image. We claim that for an ideal $I \subset A$ we have $x \in IN \Leftrightarrow x' \in IN'$. Namely, $N/IN \rightarrow N'/IN'$ is the tensor product of $B \rightarrow B'$ with N/IN and $B \rightarrow B'$ is universally injective by Algebra, Lemma 10.79.11. By More on Algebra, Lemma 15.71.5 and Algebra, Lemma 10.48.17 the map $A \rightarrow A^h$ defines an inclusion preserving bijection $I \mapsto IA^h$ on sets of ideals. We conclude that x has a content ideal in A if and only if x' has a content ideal in A^h . The assertion for $x' \in N'$ follows from Lemma 37.18.5 and Algebra, Lemma 10.86.6. \square

37.19. Flattening functors

Let S be a scheme. Recall that a functor $F : (\operatorname{Sch}/S)^{opp} \rightarrow \operatorname{Sets}$ is called limit preserving if for every directed inverse system $\{T_i\}_{i \in I}$ of affine schemes with limit T we have $F(T) = \operatorname{colim}_i F(T_i)$.

Situation 37.19.1. Let $f : X \rightarrow S$ be a morphism of schemes. Let $u : \mathcal{F} \rightarrow \mathcal{G}$ be a homomorphism of quasi-coherent \mathcal{O}_X -modules. For any scheme T over S we will denote $u_T : \mathcal{F}_T \rightarrow \mathcal{G}_T$ the base change of u to T , in other words, u_T is the pullback of u via the projection morphism $X_T = X \times_S T \rightarrow X$. In this situation we can consider the functor

(37.19.1.1)

$$F_{iso} : (\operatorname{Sch}/S)^{opp} \longrightarrow \operatorname{Sets}, \quad T \longrightarrow \begin{cases} \{*\} & \text{if } u_T \text{ is an isomorphism,} \\ \emptyset & \text{else.} \end{cases}$$

There are variants F_{inj} , F_{surj} , F_{zero} where we ask that u_T is injective, surjective, or zero.

Lemma 37.19.2. *In Situation 37.19.1.*

- (1) *Each of the functors F_{iso} , F_{inj} , F_{surj} , F_{zero} satisfies the sheaf property for the fpqc topology.*
- (2) *If f is quasi-compact and \mathcal{G} is of finite type, then F_{surj} is limit preserving.*
- (3) *If f is quasi-compact and \mathcal{F} of finite type, then F_{zero} is limit preserving.*
- (4) *If f is quasi-compact, \mathcal{F} is of finite type, and \mathcal{G} is of finite presentation, then F_{iso} is limit preserving.*

Proof. Let $\{T_i \rightarrow T\}_{i \in I}$ be an fpqc covering of schemes over S . Set $X_i = X_{T_i} = X \times_S T_i$ and $u_i = u_{T_i}$. Note that $\{X_i \rightarrow X_T\}_{i \in I}$ is an fpqc covering of X_T , see Topologies, Lemma 33.8.7. In particular, for every $x \in X_T$ there exists an $i \in I$ and an $x_i \in X_i$ mapping to x . Since $\mathcal{O}_{X_T, x} \rightarrow \mathcal{O}_{X_i, x_i}$ is flat, hence faithfully flat (see Algebra, Lemma 10.38.16) we conclude that $(u_i)_{x_i}$ is injective, surjective, bijective, or zero if and only if $(u_T)_x$ is injective, surjective, bijective, or zero. Whence part (1) of the lemma.

Proof of (2). Assume f quasi-compact and \mathcal{G} of finite type. Let $T = \lim_{i \in I} T_i$ be a directed limit of affine S -schemes and assume that u_T is surjective. Set $X_i = X_{T_i} = X \times_S T_i$ and $u_i = u_{T_i} : \mathcal{F}_i = \mathcal{F}_{T_i} \rightarrow \mathcal{G}_i = \mathcal{G}_{T_i}$. To prove part (2) we have to show that u_i is surjective for some i . Pick $i_0 \in I$ and replace I by $\{i \mid i \geq i_0\}$. Since f is quasi-compact the scheme X_{i_0} is quasi-compact. Hence we may choose affine opens $W_1, \dots, W_m \subset X$ and an affine open covering $X_{i_0} = U_{1, i_0} \cup \dots \cup U_{m, i_0}$ such that U_{j, i_0} maps into W_j under the projection morphism $X_{i_0} \rightarrow X$. For any $i \in I$ let $U_{j, i}$ be the inverse image of U_{j, i_0} . Setting $U_j = \lim_i U_{j, i}$ we see that $X_T = U_1 \cup \dots \cup U_m$ is an affine open covering of X_T . Now it suffices to show, for a given $j \in \{1, \dots, m\}$ that $u_i|_{U_{j, i}}$ is surjective for some $i = i(j) \in I$. Using Properties, Lemma 27.16.1 this translates into the following algebra problem: Let A be a ring and let $u : M \rightarrow N$ be an A -module map. Suppose that $R = \text{colim}_{i \in I} R_i$ is a directed colimit of A -algebras. If N is a finite A -module and if $u \otimes 1 : M \otimes_A R \rightarrow N \otimes_A R$ is surjective, then for some i the map $u \otimes 1 : M \otimes_A R_i \rightarrow N \otimes_A R_i$ is surjective. This is Algebra, Lemma 10.123.3 part (2).

Proof of (3). Exactly the same arguments as given in the proof of (2) reduces this to the following algebra problem: Let A be a ring and let $u : M \rightarrow N$ be an A -module map. Suppose that $R = \text{colim}_{i \in I} R_i$ is a directed colimit of A -algebras. If M is a finite A -module and if $u \otimes 1 : M \otimes_A R \rightarrow N \otimes_A R$ is zero, then for some i the map $u \otimes 1 : M \otimes_A R_i \rightarrow N \otimes_A R_i$ is zero. This is Algebra, Lemma 10.123.3 part (1).

Proof of (4). Assume f quasi-compact and \mathcal{F}, \mathcal{G} of finite presentation. Arguing in exactly the same manner as in the previous paragraph (using in addition also Properties, Lemma 27.16.2) part (3) translates into the following algebra statement: Let A be a ring and let $u : M \rightarrow N$ be an A -module map. Suppose that $R = \text{colim}_{i \in I} R_i$ is a directed colimit of A -algebras. Assume M is a finite A -module, N is a finitely presented A -module, and $u \otimes 1 : M \otimes_A R \rightarrow N \otimes_A R$ is an isomorphism. Then for some i the map $u \otimes 1 : M \otimes_A R_i \rightarrow N \otimes_A R_i$ is an isomorphism. This is Algebra, Lemma 10.123.3 part (3). \square

Situation 37.19.3. Let (A, \mathfrak{m}_A) be a local ring. Denote \mathcal{C} the category whose objects are A -algebras A' which are local rings such that the algebra structure

$A \rightarrow A'$ is a local homomorphism of local rings. A morphism between objects A', A'' of \mathcal{C} is a local homomorphism $A' \rightarrow A''$ of A -algebras. Let $A \rightarrow B$ be a local ring map of local rings and let M be a B -module. If A' is an object of \mathcal{C} we set $B' = B \otimes_A A'$ and we set $M' = M \otimes_A A'$ as a B' -module. Given $A' \in \text{Ob}(\mathcal{C})$, consider the condition

$$(37.19.3.1) \quad \forall \mathfrak{q} \in V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B') \subset \text{Spec}(B') : M'_\mathfrak{q} \text{ is flat over } A'.$$

Note the similarity with More on Algebra, Equation (15.12.1.1). In particular, if $A' \rightarrow A''$ is a morphism of \mathcal{C} and (37.19.3.1) holds for A' , then it holds for A'' , see More on Algebra, Lemma 15.12.2. Hence we obtain a functor

$$(37.19.3.2) \quad F_{lf} : \mathcal{C} \longrightarrow \text{Sets}, \quad A' \longmapsto \begin{cases} \{*\} & \text{if (37.19.3.1) holds,} \\ \emptyset & \text{else.} \end{cases}$$

Lemma 37.19.4. *In Situation 37.19.3.*

- (1) *If $A' \rightarrow A''$ is a flat morphism in \mathcal{C} then $F_{fl}(A') = F_{lf}(A'')$.*
- (2) *If $A \rightarrow B$ is essentially of finite presentation and M is a B -module of finite presentation, then F_{fl} is limit preserving: If $\{A_i\}_{i \in I}$ is a directed system of objects of \mathcal{C} , then $F_{fl}(\text{colim}_i A_i) = \text{colim}_i F_{fl}(A_i)$.*

Proof. Part (1) is a special case of More on Algebra, Lemma 15.12.3. Part (2) is a special case of More on Algebra, Lemma 15.12.4. \square

Lemma 37.19.5. *In Situation 37.19.3 suppose that $B \rightarrow C$ is a local map of local A -algebras and that $M \cong N$ as B -modules. Denote $F'_{lf} : \mathcal{C} \rightarrow \text{Sets}$ the functor associated to the pair (C, N) . If $B \rightarrow C$ is finite, then $F_{lf} = F'_{lf}$.*

Proof. Let A' be an object of \mathcal{C} . Set $C' = C \otimes_A A'$ and $N' = N \otimes_A A'$ similarly to the definitions of B', M' in Situation 37.19.3. Note that $M' \cong N'$ as B' -modules. The assumption that $B \rightarrow C$ is finite has two consequences: (a) $\mathfrak{m}_C = \sqrt{\mathfrak{m}_B C}$ and (b) $B' \rightarrow C'$ is finite. Consequence (a) implies that

$$V(\mathfrak{m}_{A'}C' + \mathfrak{m}_C C') = (\text{Spec}(C') \rightarrow \text{Spec}(B'))^{-1} V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B').$$

Suppose $\mathfrak{q} \subset V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B')$. Then $M'_\mathfrak{q}$ is flat over A' if and only if the $C'_\mathfrak{q}$ -module $N'_\mathfrak{q}$ is flat over A' (because these are isomorphic as A' -modules) if and only if for every maximal ideal \mathfrak{r} of $C'_\mathfrak{q}$ the module $N'_\mathfrak{r}$ is flat over A' (see Algebra, Lemma 10.38.19). As $B'_\mathfrak{q} \rightarrow C'_\mathfrak{q}$ is finite by (b), the maximal ideals of $C'_\mathfrak{q}$ correspond exactly to the primes of C' lying over \mathfrak{q} (see Algebra, Lemma 10.35.20) and these primes are all contained in $V(\mathfrak{m}_{A'}C' + \mathfrak{m}_C C')$ by the displayed equation above. Thus the result of the lemma holds. \square

Lemma 37.19.6. *In Situation 37.19.3 suppose that $B \rightarrow C$ is a flat local homomorphism of local rings. Set $N = M \otimes_B C$. Denote $F'_{lf} : \mathcal{C} \rightarrow \text{Sets}$ the functor associated to the pair (C, N) . Then $F_{lf} = F'_{lf}$.*

Proof. Let A' be an object of \mathcal{C} . Set $C' = C \otimes_A A'$ and $N' = N \otimes_A A' = M' \otimes_{B'} C'$ similarly to the definitions of B', M' in Situation 37.19.3. Note that

$$V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B') = \text{Spec}(\kappa(\mathfrak{m}_B) \otimes_A \kappa(\mathfrak{m}_{A'}))$$

and similarly for $V(\mathfrak{m}_{A'}C' + \mathfrak{m}_C C')$. The ring map

$$\kappa(\mathfrak{m}_B) \otimes_A \kappa(\mathfrak{m}_{A'}) \longrightarrow \kappa(\mathfrak{m}_C) \otimes_A \kappa(\mathfrak{m}_{A'})$$

is faithfully flat, hence $V(\mathfrak{m}_{A'}C' + \mathfrak{m}_C C') \rightarrow V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B')$ is surjective. Finally, if $\mathfrak{r} \in V(\mathfrak{m}_{A'}C' + \mathfrak{m}_C C')$ maps to $\mathfrak{q} \in V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B')$, then $M'_{\mathfrak{q}}$ is flat over A' if and only if $N'_{\mathfrak{r}}$ is flat over A' because $B' \rightarrow C'$ is flat, see Algebra, Lemma 10.38.8. The lemma follows formally from these remarks. \square

Situation 37.19.7. Let $f : X \rightarrow S$ be a smooth morphism with geometrically irreducible fibres. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. For any scheme T over S we will denote \mathcal{F}_T the base change of \mathcal{F} to T , in other words, \mathcal{F}_T is the pullback of \mathcal{F} via the projection morphism $X_T = X \times_S T \rightarrow X$. Note that $X_T \rightarrow T$ is smooth with geometrically irreducible fibres, see Morphisms, Lemma 28.35.5 and More on Morphisms, Lemma 36.22.2. Let $p \geq 0$ be an integer. Given a point $t \in T$ consider the condition

$$(37.19.7.1) \quad \mathcal{F}_T \text{ is free of rank } p \text{ in a neighbourhood of } \xi_t$$

where ξ_t is the generic point of the fibre X_t . This condition for all $t \in T$ is stable under base change, and hence we obtain a functor

$$(37.19.7.2) \quad H_p : (Sch/S)^{opp} \longrightarrow Sets, \quad T \longrightarrow \begin{cases} \{*\} & \text{if } \mathcal{F}_T \text{ satisfies (37.19.7.1) } \forall t \in T, \\ \emptyset & \text{else.} \end{cases}$$

Lemma 37.19.8. *In Situation 37.19.7.*

- (1) *The functor H_p satisfies the sheaf property for the fpqc topology.*
- (2) *If \mathcal{F} is of finite presentation, then functor H_p is limit preserving.*

Proof. Let $\{T_i \rightarrow T\}_{i \in I}$ be an fpqc¹ covering of schemes over S . Set $X_i = X_{T_i} = X \times_S T_i$ and denote \mathcal{F}_i the pullback of \mathcal{F} to X_i . Assume that \mathcal{F}_i satisfies (37.19.7.1) for all i . Pick $t \in T$ and let $\xi_t \in X_T$ denote the generic point of X_t . We have to show that \mathcal{F} is free in a neighbourhood of ξ_t . For some $i \in I$ we can find a $t_i \in T_i$ mapping to t . Let $\xi_i \in X_i$ denote the generic point of X_{t_i} , so that ξ_i maps to ξ_t . The fact that \mathcal{F}_i is free of rank p in a neighbourhood of ξ_i implies that $(\mathcal{F}_i)_{x_i} \cong \mathcal{O}_{X_i, x_i}^{\oplus p}$ which implies that $\mathcal{F}_{T, \xi_t} \cong \mathcal{O}_{X_T, \xi_t}^{\oplus p}$ as $\mathcal{O}_{X_T, \xi_t} \rightarrow \mathcal{O}_{X_i, x_i}$ is flat, see for example Algebra, Lemma 10.75.5. Thus there exists an affine neighbourhood U of ξ_t in X_T and a surjection $\mathcal{O}_U^{\oplus p} \rightarrow \mathcal{F}_U = \mathcal{F}_T|_U$, see Modules, Lemma 17.9.4. After shrinking T we may assume that $U \rightarrow T$ is surjective. Hence $U \rightarrow T$ is a smooth morphism of affines with geometrically irreducible fibres. Moreover, for every $t' \in T$ we see that the induced map

$$\alpha : \mathcal{O}_{U, \xi_{t'}}^{\oplus p} \longrightarrow \mathcal{F}_{U, \xi_{t'}}$$

is an isomorphism (since by the same argument as before the module on the right is free of rank p). It follows from Lemma 37.10.1 that

$$\Gamma(U, \mathcal{O}_U^{\oplus p}) \otimes_{\Gamma(T, \mathcal{O}_T)} \mathcal{O}_{T, t'} \longrightarrow \Gamma(U, \mathcal{F}_U) \otimes_{\Gamma(T, \mathcal{O}_T)} \mathcal{O}_{T, t'}$$

is injective for every $t' \in T$. Hence we see the surjection α is an isomorphism. This finishes the proof of (1).

Assume that \mathcal{F} is of finite presentation. Let $T = \lim_{i \in I} T_i$ be a directed limit of affine S -schemes and assume that \mathcal{F}_T satisfies (37.19.7.1). Set $X_i = X_{T_i} = X \times_S T_i$ and denote \mathcal{F}_i the pullback of \mathcal{F} to X_i . Let $U \subset X_T$ denote the open subscheme

¹It is quite easy to show that H_p is a sheaf for the fpqc topology using that flat morphisms of finite presentation are open. This is all we really need later on. But it is kind of fun to prove directly that it also satisfies the sheaf condition for the fpqc topology.

of points where \mathcal{F}_T is flat over T , see More on Morphisms, Theorem 36.12.1. By assumption every generic point of every fibre is a point of U , i.e., $U \rightarrow T$ is a smooth surjective morphism with geometrically irreducible fibres. We may shrink U a bit and assume that U is quasi-compact. Using Limits, Lemma 31.3.8 we can find an $i \in I$ and a quasi-compact open $U_i \subset X_i$ whose inverse image in X_T is U . After increasing i we may assume that $\mathcal{F}_i|_{U_i}$ is flat over T_i , see Limits, Lemma 31.9.3. In particular, $\mathcal{F}_i|_{U_i}$ is finite locally free hence defines a locally constant rank function $\rho : U_i \rightarrow \{0, 1, 2, \dots\}$. Let $(U_i)_p \subset U_i$ denote the open and closed subset where ρ has value p . Let $V_i \subset T_i$ be the image of $(U_i)_p$; note that V_i is open and quasi-compact. By assumption the image of $T \rightarrow T_i$ is contained in V_i . Hence there exists an $i' \geq i$ such that $T_{i'} \rightarrow T_i$ factors through V_i by Limits, Lemma 31.3.8. Then $\mathcal{F}_{i'}$ satisfies (37.19.7.1) as desired. Some details omitted. \square

Situation 37.19.9. Let $f : X \rightarrow S$ be a morphism of schemes which is of finite type. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. For any scheme T over S we will denote \mathcal{F}_T the base change of \mathcal{F} to T , in other words, \mathcal{F}_T is the pullback of \mathcal{F} via the projection morphism $X_T = X \times_S T \rightarrow X$. Note that $X_T \rightarrow T$ is of finite type and that \mathcal{F}_T is an \mathcal{O}_{X_T} -module of finite type, see Morphisms, Lemma 28.16.4 and Modules, Lemma 17.9.2. Let $n \geq 0$. We say that \mathcal{F}_T is flat over T in dimensions $\geq n$ if for every $t \in T$ the closed subset $Z \subset X_t$ of points where \mathcal{F}_T is not flat over T (see Lemma 37.10.4) satisfies $\dim(Z) < n$ for all $t \in T$. Note that if this is the case, and if $T' \rightarrow T$ is a morphism, then $\mathcal{F}_{T'}$ is also flat in dimensions $\geq n$ over T' , see Morphisms, Lemmas 28.26.6 and 28.29.3. Hence we obtain a functor (37.19.9.1)

$$F_n : (\text{Sch}/S)^{opp} \longrightarrow \text{Sets}, \quad T \longrightarrow \begin{cases} \{*\} & \text{if } \mathcal{F}_T \text{ is flat over } T \text{ in } \dim \geq n, \\ \emptyset & \text{else.} \end{cases}$$

Lemma 37.19.10. *In Situation 37.19.9.*

- (1) *The functor F_n satisfies the sheaf property for the fpqc topology.*
- (2) *If f is quasi-compact and locally of finite presentation and \mathcal{F} is of finite presentation, then the functor F_n is limit preserving.*

Proof. Let $\{T_i \rightarrow T\}_{i \in I}$ be an fpqc covering of schemes over S . Set $X_i = X_{T_i} = X \times_S T_i$ and denote \mathcal{F}_i the pullback of \mathcal{F} to X_i . Assume that \mathcal{F}_i is flat over T_i in dimensions $\geq n$ for all i . Let $t \in T$. Choose an index i and a point $t_i \in T_i$ mapping to t . Consider the cartesian diagram

$$\begin{array}{ccc} X_{\text{Spec}(\mathcal{O}_{T,t})} & \longleftarrow & X_{\text{Spec}(\mathcal{O}_{T_i,t_i})} \\ \downarrow & & \downarrow \\ \text{Spec}(\mathcal{O}_{T,t}) & \longleftarrow & \text{Spec}(\mathcal{O}_{T_i,t_i}) \end{array}$$

As the lower horizontal morphism is flat we see from More on Morphisms, Lemma 36.12.2 that the set $Z_i \subset X_{t_i}$ where \mathcal{F}_i is not flat over T_i and the set $Z \subset X_t$ where \mathcal{F}_T is not flat over T are related by the rule $Z_i = Z_{\kappa(t_i)}$. Hence we see that \mathcal{F}_T is flat over T in dimensions $\geq n$ by Morphisms, Lemma 28.29.3.

Assume that f is quasi-compact and locally of finite presentation and that \mathcal{F} is of finite presentation. In this paragraph we first reduce the proof of (2) to the case where f is of finite presentation. Let $T = \lim_{i \in I} T_i$ be a directed limit of affine S -schemes and assume that \mathcal{F}_T is flat in dimensions $\geq n$. Set $X_i = X_{T_i} = X \times_S T_i$ and

denote \mathcal{F}_i the pullback of \mathcal{F} to X_i . We have to show that \mathcal{F}_i is flat in dimensions $\geq n$ for some i . Pick $i_0 \in I$ and replace I by $\{i \mid i \geq i_0\}$. Since T_{i_0} is affine (hence quasi-compact) there exist finitely many affine opens $W_j \subset S$, $j = 1, \dots, m$ and an affine open overing $T_{i_0} = \bigcup_{j=1, \dots, m} V_{j, i_0}$ such that $T_{i_0} \rightarrow S$ maps V_{j, i_0} into W_j . For $i \geq i_0$ denote $V_{j, i}$ the inverse image of V_{j, i_0} in T_i . If we can show, for each j , that there exists an i such that $\mathcal{F}_{V_{j, i}}$ is flat in dimensions $\geq n$, then we win. In this way we reduce to the case that S is affine. In this case X is quasi-compact and we can choose a finite affine open covering $X = W_1 \cup \dots \cup W_m$. In this case the result for $(X \rightarrow S, \mathcal{F})$ is equivalent to the result for $(\coprod W_j, \coprod \mathcal{F}|_{W_j})$. Hence we may assume that f is of finite presentation.

Assume f is of finite presentation and \mathcal{F} is of finite presentation. Let $U \subset X_T$ denote the open subscheme of points where \mathcal{F}_T is flat over T , see More on Morphisms, Theorem 36.12.1. By assumption the dimension of every fibre of $Z = X_T \setminus U$ over T has dimension $\leq n$. By Limits, Lemma 31.14.3 we can find a closed subscheme $Z \subset Z' \subset X_T$ such that $\dim(Z'_t) < n$ for all $t \in T$ and such that $Z' \rightarrow X_T$ is of finite presentation. By Limits, Lemmas 31.9.1 and 31.7.4 there exists an $i \in I$ and a closed subscheme $Z'_i \subset X_i$ of finite presentation whose base change to T is Z' . By Limits, Lemma 31.14.1 we may assume all fibres of $Z'_i \rightarrow T_i$ have dimension $< n$. By Limits, Lemma 31.9.3 we may assume that $\mathcal{F}_i|_{X_i \setminus Z'_i}$ is flat over T_i . This implies that \mathcal{F}_i is flat in dimensions $\geq n$; here we use that $Z' \rightarrow X_T$ is of finite presentation, and hence the complement $X_T \setminus Z'$ is quasi-compact! Thus part (2) is proved and the proof of the lemma is complete. \square

Situation 37.19.11. Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. For any scheme T over S we will denote \mathcal{F}_T the base change of \mathcal{F} to T , in other words, \mathcal{F}_T is the pullback of \mathcal{F} via the projection morphism $X_T = X \times_S T \rightarrow X$. Since the base change of a flat module is flat we obtain a functor

$$(37.19.11.1) \quad F_{flat} : (Sch/S)^{opp} \longrightarrow Sets, \quad T \longrightarrow \begin{cases} \{*\} & \text{if } \mathcal{F}_T \text{ is flat over } T, \\ \emptyset & \text{else.} \end{cases}$$

Lemma 37.19.12. *In Situation 37.19.11.*

- (1) *The functor F_{flat} satisfies the sheaf property for the fpqc topology.*
- (2) *If f is quasi-compact and locally of finite presentation and \mathcal{F} is of finite presentation, then the functor F_{flat} is limit preserving.*

Proof. Part (1) follows from the following statement: If $T' \rightarrow T$ is a surjective flat morphism of schemes over S , then $\mathcal{F}_{T'}$ is flat over T' if and only if \mathcal{F}_T is flat over T , see More on Morphisms, Lemma 36.12.2. Part (2) follows from Limits, Lemma 31.9.3 after reducing to the case where X and S are affine (compare with the proof of Lemma 37.19.10). \square

37.20. Flattening stratifications

Just the definitions and an important baby case.

Definition 37.20.1. Let $X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. We say that the *universal flattening of \mathcal{F} exists* if the functor F_{flat} defined in Situation 37.19.11 is representable by a scheme S' over S . We say that the *universal flattening of X exists* if the universal flattening of \mathcal{O}_X exists.

Note that if the universal flattening S'^2 of \mathcal{F} exists, then the morphism $S' \rightarrow S$ is a monomorphism of schemes such that $\mathcal{F}_{S'}$ is flat over S' and such that a morphism $T \rightarrow S$ factors through S' if and only if \mathcal{F}_T is flat over T .

We define (compare with Topology, Remark 5.27.4) a (locally finite, scheme theoretic) *stratification* of a scheme S to be given by closed subschemes $Z_i \subset S$ indexed by a partially ordered set I such that $S = \bigcup Z_i$ (set theoretically), such that every point of S has a neighbourhood meeting only a finite number of Z_i , and such that

$$Z_i \cap Z_j = \bigcup_{k \leq i, j} Z_k.$$

Setting $S_i = Z_i \setminus \bigcup_{j < i} Z_j$ the actual stratification is the decomposition $S = \coprod S_i$ into locally closed subschemes. We often only indicate the strata S_i and leave the construction of the closed subschemes Z_i to the reader. Given a stratification we obtain a monomorphism

$$S' = \coprod_{i \in I} S_i \longrightarrow S.$$

We will call this the *monomorphism associated to the stratification*. With this terminology we can define what it means to have a flattening stratification.

Definition 37.20.2. Let $X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module. We say that \mathcal{F} has a *flattening stratification* if the functor F_{flat} defined in Situation 37.19.11 is representable by a monomorphism $S' \rightarrow S$ associated to a stratification of S by locally closed subschemes. We say that X has a *flattening stratification* if \mathcal{O}_X has a flattening stratification.

When a flattening stratification exists, it is often important to understand the index set labeling the strata and its partial ordering. This often has to do with ranks of modules, as in the baby case below.

Lemma 37.20.3. *Let S be a scheme. Let \mathcal{F} be a finite type, quasi-coherent \mathcal{O}_S -module. The closed subschemes*

$$S = Z_{-1} \supset Z_0 \supset Z_1 \supset Z_2 \dots$$

defined by the fitting ideals of \mathcal{F} have the following properties

- (1) *The intersection $\bigcap Z_r$ is empty.*
- (2) *The functor $(Sch/S)^{opp} \rightarrow Sets$ defined by the rule*

$$T \longmapsto \begin{cases} \{*\} & \text{if } \mathcal{F}_T \text{ is locally generated by } \leq r \text{ sections} \\ \emptyset & \text{otherwise} \end{cases}$$

is representable by the open subscheme $S \setminus Z_r$.

- (3) *The functor $F_r : (Sch/S)^{opp} \rightarrow Sets$ defined by the rule*

$$T \longmapsto \begin{cases} \{*\} & \text{if } \mathcal{F}_T \text{ locally free rank } r \\ \emptyset & \text{otherwise} \end{cases}$$

is representable by the locally closed subscheme $Z_{r-1} \setminus Z_r$ of S .

If \mathcal{F} is of finite presentation, then $Z_r \rightarrow S$, $S \setminus Z_r \rightarrow S$, and $Z_{r-1} \setminus Z_r \rightarrow S$ are of finite presentation.

²The scheme S' is sometimes called the *universal flatificator*. In [GR71] it is called the *platificateur universel*. Existence of the universal flattening should not be confused with the type of results discussed in More on Algebra, Section 15.18.

Proof. We refer to More on Algebra, Section 15.5 for the construction of the *fitting ideals* in the algebraic setting. Here we will construct the sequence

$$0 = \mathcal{I}_{-1} \subset \mathcal{I}_0 \subset \mathcal{I}_1 \subset \dots \subset \mathcal{O}_S$$

of fitting ideals of \mathcal{F} as an \mathcal{O}_S -module. Namely, if $U \subset X$ is open, and

$$\bigoplus_{i \in I} \mathcal{O}_U \rightarrow \mathcal{O}_U^{\oplus n} \rightarrow \mathcal{F}|_U \rightarrow 0$$

is a presentation of \mathcal{F} over U , then $\mathcal{I}_r|_U$ is generated by the $(n-r) \times (n-r)$ -minors of the matrix defining the first arrow of the presentation. In particular, \mathcal{I}_r is locally generated by sections, whence quasi-coherent. If $U = \text{Spec}(A)$ and $\mathcal{F}|_U = \widetilde{M}$, then $\mathcal{I}_r|_U$ is the ideal sheaf associated to the fitting ideal $\text{Fit}_r(M)$ as in More on Algebra, Definition 15.5.3. Let $Z_r \subset S$ be the closed subscheme corresponding to \mathcal{I}_r .

For any morphism $g : T \rightarrow S$ we see from More on Algebra, Lemma 15.5.6 that \mathcal{F}_T is locally generated by $\leq r$ sections if and only if $\mathcal{I}_r \cdot \mathcal{O}_T = \mathcal{O}_T$. This proves (2).

For any morphism $g : T \rightarrow S$ we see from More on Algebra, Lemma 15.5.7 that \mathcal{F}_T is free of rank r if and only if $\mathcal{I}_r \cdot \mathcal{O}_T = \mathcal{O}_T$ and $\mathcal{I}_{r-1} \cdot \mathcal{O}_T = 0$. This proves (3).

The final statement of the lemma follows from the fact that if \mathcal{F} is of finite presentation, then each of the morphisms $Z_r \rightarrow S$ is of finite presentation as \mathcal{I}_r is locally generated by finitely many minors. This implies that $Z_{r-1} \setminus Z_r$ is a retrocompact open in Z_r and hence the morphism $Z_{r-1} \setminus Z_r \rightarrow Z_r$ is of finite presentation as well. □

Lemma 37.20.3 notwithstanding the following lemma does not hold if \mathcal{F} is a finite type quasi-coherent module. Namely, the stratification still exists but it isn't true that it represents the functor F_{flat} in general.

Lemma 37.20.4. *Let S be a scheme. Let \mathcal{F} be a quasi-coherent \mathcal{O}_S -module of finite presentation. There exists a flattening stratification $S' = \coprod_{r \geq 0} S_r$ for \mathcal{F} (relative to $\text{id}_S : S \rightarrow S$) such that $\mathcal{F}|_{S_r}$ is locally free of rank r . Moreover, each $S_r \rightarrow S$ is of finite presentation.*

Proof. Suppose that $g : T \rightarrow S$ is a morphism of schemes such that the pullback $\mathcal{F}_T = g^*\mathcal{F}$ is flat. Then \mathcal{F}_T is a flat \mathcal{O}_T -module of finite presentation. Hence \mathcal{F}_T is finite locally free, see Properties, Lemma 27.18.2. Thus $T = \coprod_{r \geq 0} T_r$, where $\mathcal{F}_T|_{T_r}$ is locally free of rank r . This implies that

$$F_{flat} = \coprod_{r \geq 0} F_r$$

in the category of Zariski sheaves on Sch/S where F_r is as in Lemma 37.20.3. It follows that F_{flat} is represented by $\coprod_{r \geq 0} (Z_{r-1} \setminus Z_r)$ where Z_r is as in Lemma 37.20.3. □

We end this section showing that if we do not insist on a canonical stratification, then we can use generic flatness to construct some stratification such that our sheaf is flat over the strata.

Lemma 37.20.5 (Generic flatness stratification). *Let $f : X \rightarrow S$ be a morphism of finite presentation between quasi-compact and quasi-separated schemes. Let \mathcal{F} be an \mathcal{O}_X -module of finite presentation. Then there exists a $t \geq 0$ and closed subschemes*

$$S \supset S_0 \supset S_1 \supset \dots \supset S_t = \emptyset$$

such that $S_i \rightarrow S$ is defined by a finite type ideal sheaf, $S_0 \subset S$ is a thickening, and \mathcal{F} pulled back to $X \times_S (S_i \setminus S_{i+1})$ is flat over $S_i \setminus S_{i+1}$.

Proof. We can find a cartesian diagram

$$\begin{array}{ccc} X & \longrightarrow & X_0 \\ \downarrow & & \downarrow \\ S & \longrightarrow & S_0 \end{array}$$

and a finitely presented \mathcal{O}_{X_0} -module \mathcal{F}_0 which pulls back to \mathcal{F} such that X_0 and S_0 are of finite type over \mathbf{Z} . See Limits, Proposition 31.4.4 and Lemmas 31.9.1 and 31.9.2. Thus we may assume X and S are of finite type over \mathbf{Z} and \mathcal{F} is a coherent \mathcal{O}_X -module.

Assume X and S are of finite type over \mathbf{Z} and \mathcal{F} is a coherent \mathcal{O}_X -module. In this case every quasi-coherent ideal is of finite type, hence we do not have to check the condition that S_i is cut out by a finite type ideal. Set $S_0 = S_{red}$ equal to the reduction of S . By generic flatness as stated in Morphisms, Proposition 28.28.2 there is a dense open $U_0 \subset S_0$ such that \mathcal{F} pulled back to $X \times_S U_0$ is flat over U_0 . Let $S_1 \subset S_0$ be the reduced closed subscheme whose underlying closed subset is $S \setminus U_0$. We continue in this way, provided $S_1 \neq \emptyset$, to find $S_0 \supset S_1 \supset \dots$. Because S is Noetherian any descending chain of closed subsets stabilizes hence we see that $S_t = \emptyset$ for some $t \geq 0$. \square

37.21. Flattening stratification over an Artinian ring

A flattening stratification exists when the base scheme is the spectrum of an Artinian ring.

Lemma 37.21.1. *Let S be the spectrum of an Artinian ring. For any scheme X over S , and any quasi-coherent \mathcal{O}_X -module there exists a universal flattening. In fact the universal flattening is given by a closed immersion $S' \rightarrow S$, and hence is a flattening stratification for \mathcal{F} as well.*

Proof. Choose an affine open covering $X = \bigcup U_i$. Then F_{flat} is the product of the functors associated to each of the pairs $(U_i, \mathcal{F}|_{U_i})$. Hence it suffices to prove the result for each $(U_i, \mathcal{F}|_{U_i})$. In the affine case the lemma follows immediately from More on Algebra, Lemma 15.10.2. \square

37.22. Flattening a map

Theorem 37.22.3 is the key to further flattening statements.

Lemma 37.22.1. *Let S be a scheme. Let $g : X' \rightarrow X$ be a flat morphism of schemes over S with X locally of finite type over S . Let \mathcal{F} be a finite type \mathcal{O}_X -module which is flat over S . If $\text{Ass}_{X/S}(\mathcal{F}) \subset g(X')$ then the canonical map*

$$\mathcal{F} \longrightarrow g_* g^* \mathcal{F}$$

is injective, and remains injective after any base change.

Proof. The final assertion means that $\mathcal{F}_T \rightarrow (g_T)_* g_T^* \mathcal{F}_T$ is injective for any morphism $T \rightarrow S$. The assumption $\text{Ass}_{X/S}(\mathcal{F}) \subset g(X')$ is preserved by base change, see Divisors, Lemma 30.7.2 and Remark 30.7.3. The same holds for the assumption of flatness and finite type. Hence it suffices to prove the injectivity of the displayed

arrow. Let $\mathcal{K} = \text{Ker}(\mathcal{F} \rightarrow g_*g^*\mathcal{F})$. Our goal is to prove that $\mathcal{K} = 0$. In order to do this it suffices to prove that $\text{WeakAss}_X(\mathcal{K}) = \emptyset$, see Divisors, Lemma 30.5.5. We have $\text{WeakAss}_X(\mathcal{K}) \subset \text{WeakAss}_X(\mathcal{F})$, see Divisors, Lemma 30.5.4. As \mathcal{F} is flat we see from Lemma 37.12.4 that $\text{WeakAss}_X(\mathcal{F}) \subset \text{Ass}_{X/S}(\mathcal{F})$. By assumption any point x of $\text{Ass}_{X/S}(\mathcal{F})$ is the image of some $x' \in X'$. Since g is flat the local ring map $\mathcal{O}_{X,x} \rightarrow \mathcal{O}_{X',x'}$ is faithfully flat, hence the map

$$\mathcal{F}_x \longrightarrow g^*\mathcal{F}_{x'} = \mathcal{F}_x \otimes_{\mathcal{O}_{X,x}} \mathcal{O}_{X',x'}$$

is injective (see Algebra, Lemma 10.79.11). This implies that $\mathcal{K}_x = 0$ as desired. \square

Lemma 37.22.2. *Let A be a ring. Let $u : M \rightarrow N$ be a surjective map of A -modules. If M is projective as an A -module, then there exists an ideal $I \subset A$ such that for any ring map $\varphi : A \rightarrow B$ the following are equivalent*

- (1) $u \otimes 1 : M \otimes_A B \rightarrow N \otimes_A B$ is an isomorphism, and
- (2) $\varphi(I) = 0$.

Proof. As M is projective we can find a projective A -module C such that $F = M \oplus C$ is a free R -module. By replacing u by $u \oplus 1 : F = M \oplus C \rightarrow N \oplus C$ we see that we may assume M is free. In this case let I be the ideal of A generated by coefficients of all the elements of $\text{Ker}(u)$ with respect to some (fixed) basis of M . The reason this works is that, since u is surjective and $\otimes_A B$ is right exact, $\text{Ker}(u \otimes 1)$ is the image of $\text{Ker}(u) \otimes_A B$ in $M \otimes_A B$. \square

Theorem 37.22.3. *In Situation 37.19.1 assume*

- (1) f is of finite presentation,
- (2) \mathcal{F} is of finite presentation, flat over S , and pure relative to S , and
- (3) u is surjective.

Then F_{iso} is representable by a closed immersion $Z \rightarrow S$. Moreover $Z \rightarrow S$ is of finite presentation if \mathcal{G} is of finite presentation.

Proof. We will use without further mention that \mathcal{F} is universally pure over S , see Lemma 37.17.3. By Lemma 37.19.2 and Descent, Lemmas 34.33.2 and 34.35.1 the question is local for the étale topology on S . Hence it suffices to prove, given $s \in S$, that there exists an étale neighbourhood of (S, s) so that the theorem holds.

Using Lemma 37.11.5 and after replacing S by an elementary étale neighbourhood of s we may assume there exists a commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ & \searrow & \swarrow \\ & S & \end{array}$$

of schemes of finite presentation over S , where g is étale, $X_s \subset g(X')$, the schemes X' and S are affine, $\Gamma(X', g^*\mathcal{F})$ a projective $\Gamma(S, \mathcal{O}_S)$ -module. Note that $g^*\mathcal{F}$ is universally pure over S , see Lemma 37.16.4. Hence by Lemma 37.17.2 we see that the open $g(X')$ contains the points of $\text{Ass}_{X/S}(\mathcal{F})$ lying over $\text{Spec}(\mathcal{O}_{S,s})$. Set

$$E = \{t \in S \mid \text{Ass}_{X_t}(\mathcal{F}_t) \subset g(X')\}.$$

By More on Morphisms, Lemma 36.20.5 E is a constructible subset of S . We have seen that $\text{Spec}(\mathcal{O}_{S,s}) \subset E$. By Morphisms, Lemma 28.23.4 we see that E

contains an open neighbourhood of s . Hence after replacing S by a smaller affine neighbourhood of s we may assume that $\text{Ass}_{X/S}(\mathcal{F}) \subset g(X')$.

Since we have assumed that u is surjective we have $F_{iso} = F_{inj}$. From Lemma 37.22.1 it follows that $u : \mathcal{F} \rightarrow \mathcal{G}$ is injective if and only if $g^*u : g^*\mathcal{F} \rightarrow g^*\mathcal{G}$ is injective, and the same remains true after any base change. Hence we have reduced to the case where, in addition to the assumptions in the theorem, $X \rightarrow S$ is a morphism of affine schemes and $\Gamma(X, \mathcal{F})$ is a projective $\Gamma(S, \mathcal{O}_S)$ -module. This case follows immediately from Lemma 37.22.2.

To see that Z is of finite presentation if \mathcal{G} is of finite presentation, combine Lemma 37.19.2 part (4) with Limits, Remark 31.5.2. \square

Lemma 37.22.4. *Let $f : X \rightarrow S$ be a morphism of schemes which is of finite presentation, flat, and pure. Let Y be a closed subscheme of X . Let $F = f_*Y$ be the Weil restriction functor of Y along f , defined by*

$$F : (\text{Sch}/S)^{opp} \rightarrow \text{Sets}, \quad T \mapsto \begin{cases} \{*\} & \text{if } Y_T \rightarrow X_T \text{ is an isomorphism,} \\ \emptyset & \text{else.} \end{cases}$$

Then F is representable by a closed immersion $Z \rightarrow S$. Moreover $Z \rightarrow S$ is of finite presentation if $Y \rightarrow S$ is.

Proof. Let \mathcal{I} be the ideal sheaf defining Y in X and let $u : \mathcal{O}_X \rightarrow \mathcal{O}_X/\mathcal{I}$ be the surjection. Then for an S -scheme T , the closed immersion $Y_T \rightarrow X_T$ is an isomorphism if and only if u_T is an isomorphism. Hence the result follows from Theorem 37.22.3. \square

37.23. Flattening in the local case

In this section we start applying the earlier material to obtain a shadow of the flattening stratification.

Theorem 37.23.1. *In Situation 37.19.3 assume A is henselian, B is essentially of finite type over A , and M is a finite B -module. Then there exists an ideal $I \subset A$ such that A/I corepresents the functor F_{lf} on the category \mathcal{C} . In other words given a local homomorphism of local rings $\varphi : A \rightarrow A'$ with $B' = B \otimes_A A'$ and $M' = M \otimes_A A'$ the following are equivalent:*

- (1) $\forall \mathfrak{q} \in V(\mathfrak{m}_{A'}B' + \mathfrak{m}_B B') \subset \text{Spec}(B') : M'_\mathfrak{q}$ is flat over A' , and
- (2) $\varphi(I) = 0$.

If B is essentially of finite presentation over A and M of finite presentation over B , then I is a finitely generated ideal.

Proof. Choose a finite type ring map $A \rightarrow C$ and a finite C -module N and a prime \mathfrak{q} of C such that $B = C_\mathfrak{q}$ and $M = N_\mathfrak{q}$. In the following, when we say “the theorem holds for $(N/C/A, \mathfrak{q})$ ” we mean that it holds for $(A \rightarrow B, M)$ where $B = C_\mathfrak{q}$ and $M = N_\mathfrak{q}$. By Lemma 37.19.6 the functor F_{lf} is unchanged if we replace B by a local ring flat over B . Hence, since A is henselian, we may apply Lemma 37.6.6 and assume that there exists a complete dévissage of $N/C/A$ at \mathfrak{q} .

Let $(A_i, B_i, M_i, \alpha_i, \mathfrak{q}_i)_{i=1, \dots, n}$ be such a complete dévissage of $N/C/A$ at \mathfrak{q} . Let $\mathfrak{q}'_i \subset A_i$ be the unique prime lying over $\mathfrak{q}_i \subset B_i$ as in Definition 37.6.4. Since $C \rightarrow A_1$ is surjective and $N \cong M_1$ as C -modules, we see by Lemma 37.19.5 it suffices to prove the theorem holds for $(M_1/A_1/A, \mathfrak{q}'_1)$. Since $B_1 \rightarrow A_1$ is finite and

\mathfrak{q}_1 is the only prime of B_1 over \mathfrak{q}'_1 we see that $(A_1)_{\mathfrak{q}'_1} \rightarrow (B_1)_{\mathfrak{q}_1}$ is finite (see Algebra, Lemma 10.40.11 or More on Morphisms, Lemma 36.33.4). Hence by Lemma 37.19.5 it suffices to prove the theorem holds for $(M_1/B_1/A, \mathfrak{q}_1)$.

At this point we may assume, by induction on the length n of the dévissage, that the theorem holds for $(M_2/B_2/A, \mathfrak{q}_2)$. (If $n = 1$, then $M_2 = 0$ which is flat over A .) Reversing the last couple of steps of the previous paragraph, using that $M_2 \cong \text{Coker}(\alpha_2)$ as B_1 -modules, we see that the theorem holds for $(\text{Coker}(\alpha_1)/B_1/A, \mathfrak{q}_1)$.

Let A' be an object of \mathcal{C} . At this point we use Lemma 37.10.1 to see that if $(M_1 \otimes_A A')_{\mathfrak{q}'}$ is flat over A' for a prime \mathfrak{q}' of $B_1 \otimes_A A'$ lying over $\mathfrak{m}_{A'}$, then $(\text{Coker}(\alpha_1) \otimes_A A')_{\mathfrak{q}'}$ is flat over A' . Hence we conclude that F_{lf} is a subfunctor of the functor F'_{lf} associated to the module $\text{Coker}(\alpha_1)_{\mathfrak{q}_1}$ over $(B_1)_{\mathfrak{q}_1}$. By the previous paragraph we know F'_{lf} is corepresented by A/J for some ideal $J \subset A$. Hence we may replace A by A/J and assume that $\text{Coker}(\alpha_1)_{\mathfrak{q}_1}$ is flat over A .

Since $\text{Coker}(\alpha_1)$ is a B_1 -module for which there exist a complete dévissage of $N_1/B_1/A$ at \mathfrak{q}_1 and since $\text{Coker}(\alpha_1)_{\mathfrak{q}_1}$ is flat over A by Lemma 37.10.2 we see that $\text{Coker}(\alpha_1)$ is free as an A -module, in particular flat as an A -module. Hence Lemma 37.10.1 implies $F_{lf}(A')$ is nonempty if and only if $\alpha \otimes 1_{A'}$ is injective. Let $N_1 = \text{Im}(\alpha_1) \subset M_1$ so that we have exact sequences

$$0 \rightarrow N_1 \rightarrow M_1 \rightarrow \text{Coker}(\alpha_1) \rightarrow 0 \quad \text{and} \quad B_1^{\oplus r_1} \rightarrow N_1 \rightarrow 0$$

The flatness of $\text{Coker}(\alpha_1)$ implies the first sequence is universally exact (see Algebra, Lemma 10.79.5). Hence $\alpha \otimes 1_{A'}$ is injective if and only if $B_1^{\oplus r_1} \otimes_A A' \rightarrow N_1 \otimes_A A'$ is an isomorphism. Finally, Theorem 37.22.3 applies to show this functor is corepresentable by A/I for some ideal I and we conclude F_{lf} is corepresentable by A/I also.

To prove the final statement, suppose that $A \rightarrow B$ is essentially of finite presentation and M of finite presentation over B . Let $I \subset A$ be the ideal such that F_{lf} is corepresented by A/I . Write $I = \bigcup I_\lambda$ where I_λ ranges over the finitely generated ideals contained in I . Then, since $F_{lf}(A/I) = \{*\}$ we see that $F_{lf}(A/I_\lambda) = \{*\}$ for some λ , see Lemma 37.19.4 part (2). Clearly this implies that $I = I_\lambda$. \square

Remark 37.23.2. Here is a scheme theoretic reformulation of Theorem 37.23.1. Let $(X, x) \rightarrow (S, s)$ be a morphism of pointed schemes which is locally of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Assume S henselian local with closed point s . There exists a closed subscheme $Z \subset S$ with the following property: for any morphism of pointed schemes $(T, t) \rightarrow (S, s)$ the following are equivalent

- (1) \mathcal{F}_T is flat over T at all points of the fibre X_t which map to $x \in X_s$, and
- (2) $\text{Spec}(\mathcal{O}_{T,t}) \rightarrow S$ factors through Z .

Moreover, if $X \rightarrow S$ is of finite presentation at x and \mathcal{F}_x of finite presentation over $\mathcal{O}_{X,x}$, then $Z \rightarrow S$ is of finite presentation.

At this point we can obtain some very general results completely for free from the result above. Note that perhaps the most interesting case is when $E = X_s$!

Lemma 37.23.3. *Let S be the spectrum of a henselian local ring with closed point s . Let $X \rightarrow S$ be a morphism of schemes which is locally of finite type. Let \mathcal{F} be a finite type quasi-coherent \mathcal{O}_X -module. Let $E \subset X_s$ be a subset. There exists a closed subscheme $Z \subset S$ with the following property: for any morphism of pointed schemes $(T, t) \rightarrow (S, s)$ the following are equivalent*

- (1) \mathcal{F}_T is flat over T at all points of the fibre X_t which map to a point of $E \subset X_s$, and
- (2) $\text{Spec}(\mathcal{O}_{T,t}) \rightarrow S$ factors through Z .

Moreover, if $X \rightarrow S$ is locally of finite presentation, \mathcal{F} is of finite presentation, and $E \subset X_s$ is closed and quasi-compact, then $Z \rightarrow S$ is of finite presentation.

Proof. For $x \in X_s$ denote $Z_x \subset S$ the closed subscheme we found in Remark 37.23.2. Then it is clear that $Z = \bigcap_{x \in E} Z_x$ works!

To prove the final statement assume X locally of finite presentation, \mathcal{F} of finite presentation and Z closed and quasi-compact. First, choose finitely many affine opens $W_j \subset X$ such that $E \subset \bigcup W_j$. It clearly suffices to prove the result for each morphism $W_j \rightarrow S$ with sheaf $\mathcal{F}|_{W_j}$ and closed subset $E \cap W_j$. Hence we may assume X is affine. In this case, More on Algebra, Lemma 15.12.4 shows that the functor defined by (1) is “limit preserving”. Hence we can show that $Z \rightarrow S$ is of finite presentation exactly as in the last part of the proof of Theorem 37.23.1. \square

Remark 37.23.4. Tracing the proof of Lemma 37.23.3 to its origins we find a long and winding road. But if we assume that

- (1) f is of finite type,
- (2) \mathcal{F} is a finite type \mathcal{O}_X -module,
- (3) $E = X_s$, and
- (4) S is the spectrum of a Noetherian complete local ring.

then there is a proof relying completely on more elementary algebra as follows: first we reduce to the case where X is affine by taking a finite affine open cover. In this case Z exists by More on Algebra, Lemma 15.13.3. The key step in this proof is constructing the closed subscheme Z step by step inside the truncations $\text{Spec}(\mathcal{O}_{S,s}/\mathfrak{m}_s^n)$. This relies on the fact that flattening stratifications always exist when the base is Artinian, and the fact that $\mathcal{O}_{S,s} = \lim \mathcal{O}_{S,s}/\mathfrak{m}_s^n$.

37.24. Variants of a lemma

In this section we discuss variants of Algebra, Lemmas 10.124.4 and 10.95.1. The most general version is Proposition 37.24.13; this was stated as [GR71, Lemma 4.2.2] but the proof in loc.cit. only gives the weaker result as stated in Lemma 37.24.5. The intricate proof of Proposition 37.24.13 is due to Ofer Gabber. As we currently have no application for the proposition we encourage the reader to skip to the next section after reading the proof of Lemma 37.24.5; this lemma will be used in the next section to prove Theorem 37.25.1.

Situation 37.24.1. Let $\varphi : A \rightarrow B$ be a local ring homomorphism of local rings which is essentially of finite type. Let M be a flat A -module, N a finite B -module and $u : N \rightarrow M$ an A -module map such that $\bar{u} : N/\mathfrak{m}_A N \rightarrow M/\mathfrak{m}_A M$ is injective.

In this situation it is our goal to show that u is A -universally injective, N is of finite presentation over B , and N is flat as an A -module. If this is true, we will say *the lemma holds* in the given situation.

Lemma 37.24.2. *If in Situation 37.24.1 the ring A is Noetherian then the lemma holds.*

Proof. Applying Algebra, Lemma 10.95.1 we see that u is injective and that $N/u(M)$ is flat over A . Then u is A -universally injective (Algebra, Lemma 10.38.11) and N is A -flat (Algebra, Lemma 10.38.12). Since B is Noetherian in this case we see that N is of finite presentation. \square

Lemma 37.24.3. *Let A_0 be a local ring. If the lemma holds for every Situation 37.24.1 with $A = A_0$, with B a localization of a polynomial algebra over A , and N of finite presentation over B , then the lemma holds for every Situation 37.24.1 with $A = A_0$.*

Proof. Let $A \rightarrow B$, $u : N \rightarrow M$ be as in Situation 37.24.1. Write $B = C/I$ where C is the localization of a polynomial algebra over A at a prime. If we can show that N is finitely presented as a C -module, then a fortiori this shows that N is finitely presented as a B -module (see Algebra, Lemma 10.6.4). Hence we may assume that B is the localization of a polynomial algebra. Next, write $N = B^{\oplus n}/K$ for some submodule $K \subset B^{\oplus n}$. Since $B/\mathfrak{m}_A B$ is Noetherian (as it is essentially of finite type over a field), there exist finitely many elements $k_1, \dots, k_s \in K$ such that for $K' = \sum Bk_i$ and $N' = B^{\oplus n}/K'$ the canonical surjection $N' \rightarrow N$ induces an isomorphism $N'/\mathfrak{m}_A N' \cong N/\mathfrak{m}_A N$. Now, if the lemma holds for the composition $u' : N' \rightarrow M$, then u' is injective, hence $N' = N$ and $u' = u$. Thus the lemma holds for the original situation. \square

Lemma 37.24.4. *If in Situation 37.24.1 the ring A is henselian then the lemma holds.*

Proof. It suffices to prove this when B is essentially of finite presentation over A and N is of finite presentation over B , see Lemma 37.24.3. Let us temporarily make the additional assumption that N is flat over A . Then N is a filtered colimit $N = \text{colim}_i F_i$ of free A -modules F_i such that the transition maps $u_{ii'} : F_i \rightarrow F_{i'}$ are injective modulo \mathfrak{m}_A , see Lemma 37.18.5. Each of the compositions $u_i : F_i \rightarrow M$ is A -universally injective by Lemma 37.7.5 wherefore $u = \text{colim } u_i$ is A -universally injective as desired.

Assume A is a henselian local ring, B is essentially of finite presentation over A , N of finite presentation over B . By Theorem 37.23.1 there exists a finitely generated ideal $I \subset A$ such that N/IN is flat over A/I and such that N/I^2N is not flat over A/I^2 unless $I = 0$. The result of the previous paragraph shows that the lemma holds for $u \bmod I : N/IN \rightarrow M/IM$ over A/I . Consider the commutative diagram

$$\begin{array}{ccccccc}
 0 & \longrightarrow & M \otimes_A I/I^2 & \longrightarrow & M/I^2M & \longrightarrow & M/IM \longrightarrow 0 \\
 & & \uparrow u & & \uparrow u & & \uparrow u \\
 & & N \otimes_A I/I^2 & \longrightarrow & N/I^2N & \longrightarrow & N/IN \longrightarrow 0
 \end{array}$$

whose rows are exact by right exactness of \otimes and the fact that M is flat over A . Note that the left vertical arrow is the map $N/IN \otimes_{A/I} I/I^2 \rightarrow M/IM \otimes_{A/I} I/I^2$, hence is injective. A diagram chase shows that the lower left arrow is injective, i.e., $\text{Tor}_{A/I^2}^1(I/I^2, M/I^2) = 0$ see Algebra, Remark 10.72.8. Hence N/I^2N is flat over A/I^2 by Algebra, Lemma 10.95.8 a contradiction unless $I = 0$. \square

The following lemma discusses the special case of Situation 37.24.1 where M has a B -module structure and u is B -linear. This is the case most often used in practice and it is significantly easier to prove than the general case.

Lemma 37.24.5. *Let $A \rightarrow B$ be a local ring homomorphism of local rings which is essentially of finite type. Let $u : N \rightarrow M$ be a B -module map. If N is a finite B -module, M is flat over A , and $\bar{u} : N/\mathfrak{m}_A N \rightarrow M/\mathfrak{m}_A M$ is injective, then u is A -universally injective, N is of finite presentation over B , and N is flat over A .*

Proof. Let $A \rightarrow A^h$ be the henselization of A . Let B' be the localization of $B \otimes_A A^h$ at the maximal ideal $\mathfrak{m}_B \otimes A^h + B \otimes \mathfrak{m}_{A^h}$. Since $B \rightarrow B'$ is flat (hence faithfully flat, see Algebra, Lemma 10.38.16), we may replace $A \rightarrow B$ with $A^h \rightarrow B'$, the module M by $M \otimes_B B'$, the module N by $N \otimes_B B'$, and u by $u \otimes \text{id}_{B'}$, see Algebra, Lemmas 10.80.2 and 10.38.8. Thus we may assume that A is a henselian local ring. In this case our lemma follows from the more general Lemma 37.24.4. \square

Lemma 37.24.6. *If in Situation 37.24.1 the ring A is a valuation ring then the lemma holds.*

Proof. Recall that an A -module is flat if and only if it is torsion free, see More on Algebra, Lemma 15.15.4. Let $T \subset N$ be the A -torsion. Then $u(T) = 0$ and N/T is A -flat. Hence N/T is finitely presented over B , see More on Algebra, Lemma 15.17.6. Thus T is a finite B -module, see Algebra, Lemma 10.5.3. Since N/T is A -flat we see that $T/\mathfrak{m}_A T \subset N/\mathfrak{m}_A N$, see Algebra, Lemma 10.38.11. As \bar{u} is injective but $u(T) = 0$, we conclude that $T/\mathfrak{m}_A T = 0$. Hence $T = 0$ by Nakayama's lemma, see Algebra, Lemma 10.19.1. At this point we have proved two out of the three assertions (N is A -flat and of finite presentation over B) and what is left is to show that u is universally injective.

By Algebra, Theorem 10.79.3 it suffices to show that $N \otimes_A Q \rightarrow M \otimes_A Q$ is injective for every finitely presented A -module Q . By More on Algebra, Lemma 15.72.3 we may assume $Q = A/(a)$ with $a \in \mathfrak{m}_A$ nonzero. Thus it suffices to show that $N/aN \rightarrow M/aM$ is injective. Let $x \in N$ with $u(x) \in aM$. By Lemma 37.18.6 we know that x has a content ideal $I \subset A$. Since I is finitely generated (More on Algebra, Lemma 15.16.2) and A is a valuation ring, we have $I = (b)$ for some b (by Algebra, Lemma 10.48.15). By More on Algebra, Lemma 15.16.3 the element $u(x)$ has content ideal I as well. Since $u(x) \in aM$ we see that $(b) \subset (a)$ by More on Algebra, Definition 15.16.1. Since $x \in bN$ we conclude $x \in aN$ as desired. \square

Consider the following situation

$$(37.24.6.1) \quad \begin{array}{l} A \rightarrow B \text{ of finite presentation, } S \subset B \text{ a multiplicative subset, and} \\ N \text{ a finitely presented } S^{-1}B\text{-module} \end{array}$$

In this situation a *pure spreadout* is an affine open $U \subset \text{Spec}(B)$ with $\text{Spec}(S^{-1}B) \subset U$ and a finitely presented $\mathcal{O}(U)$ -module N' extending N such that N' is A -projective and $N' \rightarrow N = S^{-1}N'$ is A -universally injective.

In (37.24.6.1) if $A \rightarrow A_1$ is a ring map, then we can base change: take $B_1 = B \otimes_A A_1$, let $S_1 \subset B_1$ be the image of S , and let $N_1 = N \otimes_A A_1$. This works because $S_1^{-1}B_1 = S^{-1}B \otimes_A A_1$. We will use this without further mention in the following.

Lemma 37.24.7. *In (37.24.6.1) if there exists a pure spreadout, then*

- (1) *elements of N have content ideals in A , and*

- (2) if $u : N \rightarrow M$ is a morphism to a flat A -module M such that $N/\mathfrak{m}N \rightarrow M/\mathfrak{m}M$ is injective for all maximal ideals \mathfrak{m} of A , then u is A -universally injective.

Proof. Choose U, N' as in the definition of a pure spreadout. Any element $x' \in N'$ has a content ideal in A because N' is A -projective (this can easily be seen directly, but it also follows from More on Algebra, Lemma 15.16.4 and Algebra, Example 10.88.1). Since $N' \rightarrow N$ is A -universally injective, we see that the image $x \in N$ of any $x' \in N'$ has a content ideal in A (it is the same as the content ideal of x'). For a general $x \in N$ we choose $s \in S$ such that sx is in the image of $N' \rightarrow N$ and we use that x and sx have the same content ideal.

Let $u : N \rightarrow M$ be as in (2). To show that u is A -universally injective, we may replace A by a localization at a maximal ideal (small detail omitted). Assume A is local with maximal ideal \mathfrak{m} . Pick $s \in S$ and consider the composition

$$N' \rightarrow N \xrightarrow{1/s} N \xrightarrow{u} M$$

Each of these maps is injective modulo \mathfrak{m} , hence the composition is A -universally injective by Lemma 37.7.5. Since $N = \operatorname{colim}_{s \in S} (1/s)N'$ we conclude that u is A -universally injective as a colimit of universally injective maps. \square

Lemma 37.24.8. *In (37.24.6.1) for every $\mathfrak{p} \in \operatorname{Spec}(A)$ there is a finitely generated ideal $I \subset \mathfrak{p}A_{\mathfrak{p}}$ such that over $A_{\mathfrak{p}}/I$ we have a pure spreadout.*

Proof. We may replace A by $A_{\mathfrak{p}}$. Thus we may assume A is local and \mathfrak{p} is the maximal ideal \mathfrak{m} of A . We may write $N = S^{-1}N'$ for some finitely presented B -module N' by clearing denominators in a presentation of N over $S^{-1}B$. Since $B/\mathfrak{m}B$ is Noetherian, the kernel K of $N'/\mathfrak{m}N' \rightarrow N/\mathfrak{m}N$ is finitely generated. Thus we can pick $s \in S$ such that K is annihilated by s . After replacing B by B_s which is allowed as it just means passing to an affine open subscheme of $\operatorname{Spec}(B)$, we find that the elements of S are injective on $N'/\mathfrak{m}N'$. At this point we choose a local subring $A_0 \subset A$ essentially of finite type over \mathbf{Z} , a finite type ring map $A_0 \rightarrow B_0$ such that $B = A \otimes_{A_0} B_0$, and a finite B_0 -module N'_0 such that $N' = B \otimes_{B_0} N'_0 = A \otimes_{A_0} N'_0$. We claim that $I = \mathfrak{m}_{A_0}A$ works. Namely, we have

$$N'/IN' = N'_0/\mathfrak{m}_{A_0}N'_0 \otimes_{\kappa_{A_0}} A/I$$

which is free over A/I . Multiplication by the elements of S is injective after dividing out by the maximal ideal, hence $N'/IN' \rightarrow N/IN$ is universally injective for example by Lemma 37.7.6. \square

Lemma 37.24.9. *In (37.24.6.1) assume N is A -flat, M is a flat A -module, and $u : N \rightarrow M$ is an A -module map such that $u \otimes \operatorname{id}_{\kappa(\mathfrak{p})}$ is injective for all $\mathfrak{p} \in \operatorname{Spec}(A)$. Then u is A -universally injective.*

Proof. By Algebra, Lemma 10.79.14 it suffices to check that $N/IN \rightarrow M/IM$ is injective for every ideal $I \subset A$. After replacing A by A/I we see that it suffices to prove that u is injective.

Proof that u is injective. Let $x \in N$ be a nonzero element of the kernel of u . Then there exists a weakly associated prime \mathfrak{p} of the module Ax , see Algebra, Lemma 10.65.4. Replacing A by $A_{\mathfrak{p}}$ we may assume A is local and we find a nonzero element $y \in Ax$ whose annihilator has radical equal to \mathfrak{m}_A , see Algebra, Lemma 10.65.2. Thus $\operatorname{Supp}(y) \subset \operatorname{Spec}(S^{-1}B)$ is nonempty and contained in the closed

fibre of $\text{Spec}(S^{-1}B) \rightarrow \text{Spec}(A)$. Let $I \subset \mathfrak{m}_A$ be a finitely generated ideal so that we have a pure spreadout over A/I , see Lemma 37.24.8. Then $I^n y = 0$ for some n . Now $y \in \text{Ann}_M(I^n) = \text{Ann}_A(I^n) \otimes_R N$ by flatness. Thus, to get the desired contradiction, it suffices to show that

$$\text{Ann}_A(I^n) \otimes_R N \longrightarrow \text{Ann}_A(I^n) \otimes_R M$$

is injective. Since N and M are flat and since $\text{Ann}_A(I^n)$ is annihilated by I^n , it suffices to show that $Q \otimes_A N \rightarrow Q \otimes_A M$ is injective for every A -module Q annihilated by I . This holds by our choice of I and Lemma 37.24.7 part (2). \square

Lemma 37.24.10. *Let A be a local domain. Let S be a set of finitely generated ideals of A . Assume that S is closed under products and such that $\bigcap_{I \in S} V(I)$ is the complement of the generic point of $\text{Spec}(A)$. Then $\bigcap_{I \in S} I = (0)$.*

Proof. Let $f \in A$ be nonzero. Then $V(f) \subset \bigcup_{I \in S} V(I)$. Since the constructible topology on $V(f)$ is quasi-compact (Topology, Lemma 5.22.2 and Algebra, Lemma 10.25.2) we find that $V(f) \subset V(I_1) \cup \dots \cup V(I_n)$ for some $I_j \in S$. Because $I_1 \dots I_n \in S$ we see that $V(f) \subset V(I)$ for some I . As I is finitely generated this implies that $I^m \subset (f)$ for some m and since S is closed under products we see that $I \subset (f^2)$ for some $I \in S$. Then it is not possible to have $f \in I$. \square

Lemma 37.24.11. *Let A be a local ring. Let $I, J \subset A$ be ideals. If J is finitely generated and $I \subset J^n$ for all $n \geq 1$, then $V(I)$ contains the closed points of $\text{Spec}(A) \setminus V(J)$.*

Proof. Let $\mathfrak{p} \subset A$ be a closed point of $\text{Spec}(A) \setminus V(J)$. We want to show that $I \subset \mathfrak{p}$. If not, then some $f \in I$ maps to a nonzero element of A/\mathfrak{p} . Note that $V(J) \cap \text{Spec}(A/\mathfrak{p})$ is the set of non-generic points. Hence by Lemma 37.24.10 applied to the collection of ideals $J^n A/\mathfrak{p}$ we conclude that the image of f is zero in A/\mathfrak{p} . \square

Lemma 37.24.12. *Let A be a local ring. Let $I \subset A$ be an ideal. Let $U \subset \text{Spec}(A)$ be quasi-compact open. Let M be an A -module. Assume that*

- (1) M/IM is flat over A/I ,
- (2) M is flat over U ,

Then $M/I_2 M$ is flat over A/I_2 where $I_2 = \text{Ker}(I \rightarrow \Gamma(U, I/I^2))$.

Proof. It suffices to show that $M \otimes_A I/I_2 \rightarrow IM/I_2 M$ is injective, see Algebra, Lemma 10.95.9. This is true over U by assumption (2). Thus it suffices to show that $M \otimes_A I/I_2$ injects into its sections over U . We have $M \otimes_A I/I_2 = M/IM \otimes_A I/I_2$ and M/IM is a filtered colimit of finite free A/I -modules (Algebra, Theorem 10.78.4). Hence it suffices to show that I/I_2 injects into its sections over U , which follows from the construction of I_2 . \square

Proposition 37.24.13. *Let $A \rightarrow B$ be a local ring homomorphism of local rings which is essentially of finite type. Let M be a flat A -module, N a finite B -module and $u : N \rightarrow M$ an A -module map such that $\bar{u} : N/\mathfrak{m}_A N \rightarrow M/\mathfrak{m}_A M$ is injective. Then u is A -universally injective, N is of finite presentation over B , and N is flat over A .*

Proof. We may assume that B is the localization of a finitely presented A -algebra B_0 and that N is the localization of a finitely presented B_0 -module M_0 , see Lemma

37.24.3. By Lemma 37.20.5 there exists a “generic flatness stratification” for \widetilde{M}_0 on $\text{Spec}(B_0)$ over $\text{Spec}(A)$. Translating back to N we find a sequence of closed subschemes

$$S = \text{Spec}(A) \supset S_0 \supset S_1 \supset \dots \supset S_t = \emptyset$$

with $S_i \subset S$ cut out by a finitely generated ideal of A such that the pullback of \widetilde{N} to $\text{Spec}(B) \times_S (S_i \setminus S_{i+1})$ is flat over $S_i \setminus S_{i+1}$. We will prove the proposition by induction on t (the base case $t = 1$ will be proved in parallel with the other steps). Let $\text{Spec}(A/J_i)$ be the scheme theoretic closure of $S_i \setminus S_{i+1}$.

Claim 1. $N/J_i N$ is flat over A/J_i . This is immediate for $i = t - 1$ and follows from the induction hypothesis for $i > 0$. Thus we may assume $t > 1$, $S_{t-1} \neq \emptyset$, and $J_0 = 0$ and we have to prove that N is flat. Let $J \subset A$ be the ideal defining S_1 . By induction on t again, we also have flatness modulo powers of J . Let A^h be the henselization of A and let B' be the localization of $B \otimes_A A^h$ at the maximal ideal $\mathfrak{m}_B \otimes A^h + B \otimes \mathfrak{m}_{A^h}$. Then $B \rightarrow B'$ is faithfully flat. Set $N' = N \otimes_B B'$. Note that N' is A^h -flat if and only if N is A -flat. By Theorem 37.23.1 there is a smallest ideal $I \subset A^h$ such that N'/IN' is flat over A^h/I , and I is finitely generated. By the above $I \subset J^n A^h$ for all $n \geq 1$. Let $S_i^h \subset \text{Spec}(A^h)$ be the inverse image of $S_i \subset \text{Spec}(A)$. By Lemma 37.24.11 we see that $V(I)$ contains the closed points of $U = \text{Spec}(A^h) - S_1^h$. By construction N' is A^h -flat over U . By Lemma 37.24.12 we see that $N'/I_2 N'$ is flat over A/I_2 , where $I_2 = \text{Ker}(I \rightarrow \Gamma(U, I/I^2))$. Hence $I = I_2$ by minimality of I . This implies that $I = I^2$ locally on U , i.e., we have $I\mathcal{O}_{U,u} = (0)$ or $I\mathcal{O}_{U,u} = (1)$ for all $u \in U$. Since $V(I)$ contains the closed points of U we see that $I = 0$ on U . Since $U \subset \text{Spec}(A^h)$ is scheme theoretically dense (because replaced A by A/J_0 in the beginning of this paragraph), we see that $I = 0$. Thus N' is A^h -flat and hence Claim 1 holds.

We return to the situation as laid out before Claim 1. With A^h the henselization of A , with B' the localization of $B \otimes_A A^h$ at the maximal ideal $\mathfrak{m}_B \otimes A^h + B \otimes \mathfrak{m}_{A^h}$, and with $N' = N \otimes_B B'$ we now see that the flattening ideal $I \subset A^h$ of Theorem 37.23.1 is nilpotent. If $\text{nil}(A^h)$ denotes the ideal of nilpotent elements, then $\text{nil}(A^h) = \text{nil}(A)A^h$ (More on Algebra, Lemma 15.34.5). Hence there exists a finitely generated nilpotent ideal $I_0 \subset A$ such that $N/I_0 N$ is flat over A/I_0 .

Claim 2. For every prime ideal $\mathfrak{p} \subset A$ the map $\kappa(\mathfrak{p}) \otimes_A N \rightarrow \kappa(\mathfrak{p}) \otimes_A M$ is injective. We say \mathfrak{p} is bad if this is false. Suppose that C is a nonempty chain of bad primes and set $\mathfrak{p}^* = \bigcup_{\mathfrak{p} \in C} \mathfrak{p}$. By Lemma 37.24.8 there is a finitely generated ideal $\mathfrak{a} \subset \mathfrak{p}^* A_{\mathfrak{p}^*}$ such that there is a pure spreadout over $V(\mathfrak{a})$. If \mathfrak{p}^* were good, then it would follow from Lemma 37.24.7 that the points of $V(\mathfrak{a})$ are good. However, since \mathfrak{a} is finitely generated and since $\mathfrak{p}^* A_{\mathfrak{p}^*} = \bigcup_{\mathfrak{p} \in C} A_{\mathfrak{p}^*}$ we see that $V(\mathfrak{a})$ contains a $\mathfrak{p} \in C$, contradiction. Hence \mathfrak{p}^* is bad. By Zorn's lemma, if there exists a bad prime, there exists a maximal one, say \mathfrak{p} . In other words, we may assume every $\mathfrak{p}' \supset \mathfrak{p}$, $\mathfrak{p}' \neq \mathfrak{p}$ is good. In this case we see that for every $f \in A$, $f \notin \mathfrak{p}$ the map $u \otimes \text{id}_{A/(\mathfrak{p}+f)}$ is universally injective, see Lemma 37.24.9. Thus it suffices to show that $N/\mathfrak{p}N$ is separated for the topology defined by the submodules $f(N/\mathfrak{p}N)$. Since $B \rightarrow B'$ is faithfully flat, it is enough to prove the same for the module $N'/\mathfrak{p}N'$. By Lemma 37.18.5 and More on Algebra, Lemma 15.16.4 elements of $N'/\mathfrak{p}N'$ have content ideals in $A^h/\mathfrak{p}A^h$. Thus it suffices to show that $\bigcap_{f \in A, f \notin \mathfrak{p}} f(A^h/\mathfrak{p}A^h) = 0$. Then it suffices to show the same for $A^h/\mathfrak{q}A^h$ for every prime $\mathfrak{q} \subset A^h$ minimal over $\mathfrak{p}A^h$. Because $A \rightarrow A^h$ is the henselization, every \mathfrak{q} contracts to \mathfrak{p} and every $\mathfrak{q}' \supset \mathfrak{q}$,

$\mathfrak{q}' \neq \mathfrak{q}$ contracts to a prime \mathfrak{p}' which strictly contains \mathfrak{p} . Thus we get the vanishing of the intersections from Lemma 37.24.10.

At this point we can put everything together. Namely, using Claim 1 and Claim 2 we see that $N/I_0N \rightarrow M/I_0M$ is A/I_0 -universally injective by Lemma 37.24.9. Then the diagrams

$$\begin{array}{ccc} N \otimes_A (I_0^n/I_0^{n+1}) & \longrightarrow & M \otimes_A (I_0^n/I_0^{n+1}) \\ \downarrow & & \parallel \\ I_0^n N/I_0^{n+1} N & \longrightarrow & I_0^n M/I_0^{n+1} M \end{array}$$

show that the left vertical arrows are injective. Hence by Algebra, Lemma 10.95.9 we see that N is flat. In a similar way the universal injectivity of u can be reduced (even without proving flatness of N first) to the one modulo I_0 . This finishes the proof. \square

37.25. Flat finite type modules, Part III

The following result is one of the main results of this chapter.

Theorem 37.25.1. *Let $f : X \rightarrow S$ be locally of finite type. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module of finite type. Let $x \in X$ with image $s \in S$. The following are equivalent*

- (1) \mathcal{F} is flat at x over S , and
- (2) for every $x' \in \text{Ass}_{X_s}(\mathcal{F}_s)$ which specializes to x we have that \mathcal{F} is flat at x' over S .

Proof. It is clear that (1) implies (2) as $\mathcal{F}_{x'}$ is a localization of \mathcal{F}_x for every point which specializes to x . Set $A = \mathcal{O}_{S,s}$, $B = \mathcal{O}_{X,x}$ and $N = \mathcal{F}_x$. Let $\Sigma \subset B$ be the multiplicative subset of B of elements which act as nonzerodivisors on $N/\mathfrak{m}_A N$. Assumption (2) implies that $\Sigma^{-1}N$ is A -flat by the description of $\text{Spec}(\Sigma^{-1}N)$ in Lemma 37.7.1. On the other hand, the map $N \rightarrow \Sigma^{-1}N$ is injective modulo \mathfrak{m}_A by construction. Hence applying Lemma 37.24.5 we win. \square

Now we apply this directly to obtain the following useful results.

Lemma 37.25.2. *Let S be a local scheme with closed point s . Let $f : X \rightarrow S$ be locally of finite type. Let \mathcal{F} be a finite type \mathcal{O}_X -module. Assume that*

- (1) every point of $\text{Ass}_{X/S}(\mathcal{F})$ specializes to a point of the closed fibre X_s ³,
- (2) \mathcal{F} is flat over S at every point of X_s .

Then \mathcal{F} is flat over S .

Proof. This is immediate from the fact that it suffices to check for flatness at points of the relative assassin of \mathcal{F} over S by Theorem 37.25.1. \square

³For example this holds if f is finite type and \mathcal{F} is pure along X_s , or if f is proper.

37.26. Universal flattening

If $f : X \rightarrow S$ is a proper, finitely presented morphism of schemes then one can find a universal flattening of f . In this section we discuss this and some of its variants.

Lemma 37.26.1. *In Situation 37.19.7. For each $p \geq 0$ the functor H_p (37.19.7.2) is representable by a locally closed immersion $S_p \rightarrow S$. If \mathcal{F} is of finite presentation, then $S_p \rightarrow S$ is of finite presentation.*

Proof. For each S we will prove the statement for all $p \geq 0$ concurrently. The functor H_p is a sheaf for the fppf topology by Lemma 37.19.8. Hence combining Descent, Lemma 34.35.1, More on Morphisms, Lemma 36.37.1, and Descent, Lemma 34.20.1 we see that the question is local for the étale topology on S . In particular, the question is Zariski local on S .

For $s \in S$ denote ξ_s the unique generic point of the fibre X_s . Note that for every $s \in S$ the restriction \mathcal{F}_s of \mathcal{F} is locally free of some rank $p(s) \geq 0$ in some neighbourhood of ξ_s . (As X_s is irreducible and smooth this follows from generic flatness for \mathcal{F}_s over X_s , see Algebra, Lemma 10.114.1 although this is overkill.) For future reference we note that

$$p(s) = \dim_{\kappa(\xi_s)}(\mathcal{F}_{\xi_s} \otimes_{\mathcal{O}_{X, \xi_s}} \kappa(\xi_s)).$$

In particular $H_{p(s)}(s)$ is nonempty and $H_q(s)$ is empty if $q \neq p(s)$.

Let $U \subset X$ be an open subscheme. As $f : X \rightarrow S$ is smooth, it is open. It is immediate from (37.19.7.2) that the functor H_p for the pair $(f|_U : U \rightarrow f(U), \mathcal{F}|_U)$ and the functor H_p for the pair $(f|_{f^{-1}(f(U))}, \mathcal{F}|_{f^{-1}(f(U))})$ are the same. Hence to prove the existence of S_p over $f(U)$ we may always replace X by U .

Pick $s \in S$. There exists an affine open neighbourhood U of ξ_s such that $\mathcal{F}|_U$ can be generated by at most $p(s)$ elements. By the arguments above we see that in order to prove the statement for $H_{p(s)}$ in an neighbourhood of s we may assume that \mathcal{F} is generated by $p(s)$ elements, i.e., that there exists a surjection

$$u : \mathcal{O}_X^{\oplus p(s)} \longrightarrow \mathcal{F}$$

In this case it is clear that $H_{p(s)}$ is equal to F_{iso} (37.19.1.1) for the map u (this follows immediately from Lemma 37.18.1 but also from Lemma 37.11.1 after shrinking a bit more so that both S and X are affine.) Thus we may apply Theorem 37.22.3 to see that $H_{p(s)}$ is representable by a closed immersion in a neighbourhood of s .

The result follows formally from the above. Namely, the arguments above show that locally on S the function $s \mapsto p(s)$ is bounded. Hence we may use induction on $p = \max_{s \in S} p(s)$. The functor H_p is representable by a closed immersion $S_p \rightarrow S$ by the above. Replace S by $S \setminus S_p$ which drops the maximum by at least one and we win by induction hypothesis.

To see that $S_p \rightarrow S$ is of finite presentation if \mathcal{F} is of finite presentation combine Lemma 37.19.8 part (2) with Limits, Remark 31.5.2. \square

Lemma 37.26.2. *In Situation 37.19.9. Let $h : X' \rightarrow X$ be an étale morphism. Set $\mathcal{F}' = h^* \mathcal{F}$ and $f' = f \circ h$. Let F'_n be (37.19.9.1) associated to $(f' : X' \rightarrow S, \mathcal{F}')$. Then F_n is a subfunctor of F'_n and if $h(X') \supset \text{Ass}_{X/S}(\mathcal{F})$, then $F_n = F'_n$.*

Proof. Let $T \rightarrow S$ be any morphism. Then $h_T : X'_T \rightarrow X_T$ is étale as a base change of the étale morphism g . For $t \in T$ denote $Z \subset X_t$ the set of points where \mathcal{F}_T is not flat over T , and similarly denote $Z' \subset X'_t$ the set of points where \mathcal{F}'_T is not flat over T . As $\mathcal{F}'_T = h_T^* \mathcal{F}_T$ we see that $Z' = h_T^{-1}(Z)$, see Morphisms, Lemma 28.26.11. Hence $Z' \rightarrow Z$ is an étale morphism, so $\dim(Z') \leq \dim(Z)$ (for example by Descent, Lemma 34.17.2 or just because an étale morphism is smooth of relative dimension 0). This implies that $F_n \subset F'_n$.

Finally, suppose that $h(X') \supset \text{Ass}_{X/S}(\mathcal{F})$ and that $T \rightarrow S$ is a morphism such that $F'_n(T)$ is nonempty, i.e., such that \mathcal{F}'_T is flat in dimensions $\geq n$ over T . Pick a point $t \in T$ and let $Z \subset X_t$ and $Z' \subset X'_t$ be as above. To get a contradiction assume that $\dim(Z) \geq n$. Pick a generic point $\xi \in Z$ corresponding to a component of dimension $\geq n$. Let $x \in \text{Ass}_{X_t}(\mathcal{F}_t)$ be a generalization of ξ . Then x maps to a point of $\text{Ass}_{X/S}(\mathcal{F})$ by Divisors, Lemma 30.7.2 and Remark 30.7.3. Thus we see that x is in the image of h_T , say $x = h_T(x')$ for some $x' \in X'_T$. But $x' \notin Z'$ as $x \rightsquigarrow \xi$ and $\dim(Z') < n$. Hence \mathcal{F}'_T is flat over T at x' which implies that \mathcal{F}_T is flat at x over T (by Morphisms, Lemma 28.26.11). Since this holds for every such x we conclude that \mathcal{F}_T is flat over T at ξ by Theorem 37.25.1 which is the desired contradiction. \square

Lemma 37.26.3. *Assume that $X \rightarrow S$ is a smooth morphism of affine schemes with geometrically irreducible fibres of dimension d and that \mathcal{F} is a quasi-coherent \mathcal{O}_X -module of finite presentation. Then $F_d = \coprod_{p=0, \dots, c} H_p$ for some $c \geq 0$ with F_d as in (37.19.9.1) and H_p as in (37.19.7.2).*

Proof. As X is affine and \mathcal{F} is quasi-coherent of finite presentation we know that \mathcal{F} can be generated by $c \geq 0$ elements. Then $\dim_{\kappa(x)}(\mathcal{F}_x \otimes \kappa(x))$ in any point $x \in X$ never exceeds c . In particular $H_p = \emptyset$ for $p > c$. Moreover, note that there certainly is an inclusion $\coprod H_p \rightarrow F_d$. Having said this the content of the lemma is that, if a base change \mathcal{F}_T is flat in dimensions $\geq d$ over T and if $t \in T$, then \mathcal{F}_T is free of some rank r in an open neighbourhood $U \subset X_T$ of the unique generic point ξ of X_t . Namely, then H_r contains the image of U which is an open neighbourhood of t . The existence of U follows from More on Morphisms, Lemma 36.13.7. \square

Lemma 37.26.4. *In Situation 37.19.9. Let $s \in S$ let $d \geq 0$. Assume*

- (1) *there exists a complete dévissage of $\mathcal{F}/X/S$ over some point $s \in S$,*
- (2) *X is of finite presentation over S ,*
- (3) *\mathcal{F} is an \mathcal{O}_X -module of finite presentation, and*
- (4) *\mathcal{F} is flat in dimensions $\geq d + 1$ over S .*

Then after possibly replacing S by an open neighbourhood of s the functor F_d (37.19.9.1) is representable by a monomorphism $Z_d \rightarrow S$ of finite presentation.

Proof. A preliminary remark is that X, S are affine schemes and that it suffices to prove F_d is representable by a closed subscheme on the category of affine schemes over S . Hence throughout the proof of the lemma we work in the category of affine schemes over S .

Let $(Z_k, Y_k, i_k, \pi_k, \mathcal{G}_k, \alpha_k)_{k=1, \dots, n}$ be a complete dévissage of $\mathcal{F}/X/S$ over s , see Definition 37.5.1. We will use induction on the length n of the dévissage. Recall that $Y_k \rightarrow S$ is smooth with geometrically irreducible fibres, see Definition 37.4.1. Let d_k be the relative dimension of Y_k over S . Recall that $i_{k,*} \mathcal{G}_k = \text{Coker}(\alpha_k)$

and that i_k is a closed immersion. By the definitions referenced above we have $d_1 = \dim(\text{Supp}(\mathcal{F}_s))$ and

$$d_k = \dim(\text{Supp}(\text{Coker}(\alpha_{k-1})_s)) = \dim(\text{Supp}(\mathcal{G}_{k,s}))$$

for $k = 2, \dots, n$. It follows that $d_1 > d_2 > \dots > d_n \geq 0$ because α_k is an isomorphism in the generic point of $(Y_k)_s$.

Note that i_1 is a closed immersion and $\mathcal{F} = i_{1,*}\mathcal{G}_1$. Hence for any morphism of schemes $T \rightarrow S$ with T affine, we have $\mathcal{F}_T = i_{1,T,*}\mathcal{G}_{1,T}$ and $i_{1,T}$ is still a closed immersion of schemes over T . Thus \mathcal{F}_T is flat in dimensions $\geq d$ over T if and only if $\mathcal{G}_{1,T}$ is flat in dimensions $\geq d$ over T . Because $\pi_1 : Z_1 \rightarrow Y_1$ is finite we see in the same manner that $\mathcal{G}_{1,T}$ is flat in dimensions $\geq d$ over T if and only if $\pi_{1,T,*}\mathcal{G}_{1,T}$ is flat in dimensions $\geq d$ over T . The same arguments work for “flat in dimensions $\geq d + 1$ ” and we conclude in particular that $\pi_{1,*}\mathcal{G}_1$ is flat over S in dimensions $\geq d + 1$ by our assumption on \mathcal{F} .

Suppose that $d_1 > d$. It follows from the discussion above that in particular $\pi_{1,*}\mathcal{G}_1$ is flat over S at the generic point of $(Y_1)_s$. By Lemma 37.11.1 we may replace S by an affine neighbourhood of s and assume that α_1 is S -universally injective. Because α_1 is S -universally injective, for any morphism $T \rightarrow S$ with T affine, we have a short exact sequence

$$0 \rightarrow \mathcal{O}_{Y_1,T}^{\oplus r_1} \rightarrow \pi_{1,T,*}\mathcal{G}_{1,T} \rightarrow \text{Coker}(\alpha_1)_T \rightarrow 0$$

and still the first arrow is T -universally injective. Hence the set of points of $(Y_1)_T$ where $\pi_{1,T,*}\mathcal{G}_{1,T}$ is flat over T is the same as the set of points of $(Y_1)_T$ where $\text{Coker}(\alpha_1)_T$ is flat over S . In this way the question reduces to the sheaf $\text{Coker}(\alpha_1)$ which has a complete dévissage of length $n - 1$ and we win by induction.

If $d_1 < d$ then F_d is represented by S and we win.

The last case is the case $d_1 = d$. This case follows from a combination of Lemma 37.26.3 and Lemma 37.26.1. \square

Theorem 37.26.5. *In Situation 37.19.9. Assume moreover that f is of finite presentation, that \mathcal{F} is an \mathcal{O}_X -module of finite presentation, and that \mathcal{F} is pure relative to S . Then F_n is representable by a monomorphism $Z_n \rightarrow S$ of finite presentation.*

Proof. The functor F_n is a sheaf for the fppf topology by Lemma 37.19.10. Hence combining Descent, Lemma 34.35.1, More on Morphisms, Lemma 36.37.1, and Descent, Lemmas 34.19.29 and 34.19.11 we see that the question is local for the étale topology on S .

In particular the situation is local for the Zariski topology on S and we may assume that S is affine. In this case the dimension of the fibres of f is bounded above, hence we see that F_n is representable for n large enough. Thus we may use descending induction on n . Suppose that we know F_{n+1} is representable by a monomorphism $Z_{n+1} \rightarrow S$ of finite presentation. Consider the base change $X_{n+1} = Z_{n+1} \times_S X$ and the pullback \mathcal{F}_{n+1} of \mathcal{F} to X_{n+1} . The morphism $Z_{n+1} \rightarrow S$ is quasi-finite as it is a monomorphism of finite presentation, hence Lemma 37.15.4 implies that \mathcal{F}_{n+1} is pure relative to Z_{n+1} . Since F_n is a subfunctor of F_{n+1} we conclude that in order to prove the result for F_n it suffices to prove the result for the corresponding functor for the situation $\mathcal{F}_{n+1}/X_{n+1}/Z_{n+1}$. In this way we reduce to proving the

result for F_n in case $S_{n+1} = S$, i.e., we may assume that \mathcal{F} is flat in dimensions $\geq n+1$ over S .

Fix n and assume \mathcal{F} is flat in dimensions $\geq n+1$ over S . To finish the proof we have to show that F_n is representable by a monomorphism $Z_n \rightarrow S$ of finite presentation. Since the question is local in the étale topology on S it suffices to show that for every $s \in S$ there exists an elementary étale neighbourhood $(S', s') \rightarrow (S, s)$ such that the result holds after base change to S' . Thus by Lemma 37.5.8 we may assume there exist étale morphisms $h_j : Y_j \rightarrow X$, $j = 1, \dots, m$ such that for each i there exists a complete dévissage of $\mathcal{F}_j/Y_j/S$ over s , where \mathcal{F}_j is the pullback of \mathcal{F} to Y_j and such that $X_s \subset \bigcup h_j(Y_j)$. Note that by Lemma 37.26.2 the sheaves \mathcal{F}_j are still flat over in dimensions $\geq n+1$ over S . Set $W = \bigcup h_j(Y_j)$, which is a quasi-compact open of X . As \mathcal{F} is pure along X_s we see that

$$E = \{t \in S \mid \text{Ass}_{X_t}(\mathcal{F}_t) \subset W\}.$$

contains all generalizations of s . By More on Morphisms, Lemma 36.20.5 E is a constructible subset of S . We have seen that $\text{Spec}(\mathcal{O}_{S,s}) \subset E$. By Morphisms, Lemma 28.23.4 we see that E contains an open neighbourhood of s . Hence after shrinking S we may assume that $E = S$. It follows from Lemma 37.26.2 that it suffices to prove the lemma for the functor F_n associated to $X = \coprod Y_j$ and $\mathcal{F} = \coprod \mathcal{F}_j$. If $F_{j,n}$ denotes the functor for $Y_j \rightarrow S$ and the sheaf \mathcal{F}_j we see that $F_n = \prod F_{j,n}$. Hence it suffices to prove each $F_{j,n}$ is representable by some monomorphism $Z_{j,n} \rightarrow S$ of finite presentation, since then

$$Z_n = Z_{1,n} \times_S \dots \times_S Z_{m,n}$$

Thus we have reduced the theorem to the special case handled in Lemma 37.26.4. \square

We make explicit what the theorem means in terms of universal flattenings in the following lemma.

Lemma 37.26.6. *Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module.*

- (1) *If f is of finite presentation, \mathcal{F} is an \mathcal{O}_X -module of finite presentation, and \mathcal{F} is pure relative to S , then there exists a universal flattening $S' \rightarrow S$ of \mathcal{F} . Moreover $S' \rightarrow S$ is a monomorphism of finite presentation.*
- (2) *If f is of finite presentation and X is pure relative to S , then there exists a universal flattening $S' \rightarrow S$ of X . Moreover $S' \rightarrow S$ is a monomorphism of finite presentation.*
- (3) *If f is proper and of finite presentation and \mathcal{F} is an \mathcal{O}_X -module of finite presentation, then there exists a universal flattening $S' \rightarrow S$ of \mathcal{F} . Moreover $S' \rightarrow S$ is a monomorphism of finite presentation.*
- (4) *If f is proper and of finite presentation then there exists a universal flattening $S' \rightarrow S$ of X .*

Proof. These statements follow immediately from Theorem 37.26.5 applied to $F_0 = F_{flat}$ and the fact that if f is proper then \mathcal{F} is automatically pure over the base, see Lemma 37.16.1. \square

37.27. Blowing up and flatness

In this section we begin our discussion of results of the form: “After a blowup the strict transform becomes flat”. We will use the following (more or less standard) notation in this section. If $X \rightarrow S$ is a morphism of schemes, \mathcal{F} is a quasi-coherent module on X , and $T \rightarrow S$ is a morphism of schemes, then we denote \mathcal{F}_T the pullback of \mathcal{F} to the base change $X_T = X \times_S T$.

Remark 37.27.1. Let S be a quasi-compact and quasi-separated scheme. Let $f : X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent module on X . Let $U \subset S$ be a quasi-compact open subscheme. Given a U -admissible blowup $S' \rightarrow S$ we denote X' the strict transform of X and \mathcal{F}' the strict transform of \mathcal{F} which we think of as a quasi-coherent module on X' (via Divisors, Lemma 30.19.2). Let P be a property of $\mathcal{F}/X/S$ which is stable under strict transform (as above) for U -admissible blowups. The general problem in this section is: Show (under auxiliary conditions on $\mathcal{F}/X/S$) there exists a U -admissible blowup $S' \rightarrow S$ such that the strict transform $\mathcal{F}'/X'/S'$ has P .

The general strategy will be to use that a composition of U -admissible blowups is a U -admissible blowup, see Divisors, Lemma 30.20.2. In fact, we will make use of the more precise Divisors, Lemma 30.18.12 and combine it with Divisors, Lemma 30.19.6. The result is that it suffices to find a sequence of U -admissible blowups

$$S = S_0 \leftarrow S_1 \leftarrow \dots \leftarrow S_n$$

such that, setting $\mathcal{F}_0 = \mathcal{F}$ and $X_0 = X$ and setting \mathcal{F}_i/X_i equal to the strict transform of $\mathcal{F}_{i-1}/X_{i-1}$, we arrive at $\mathcal{F}_n/X_n/S_n$ with property P .

In particular, choose a finite type quasi-coherent sheaf of ideals $\mathcal{I} \subset \mathcal{O}_S$ such that $V(\mathcal{I}) = S \setminus U$, see Properties, Lemma 27.22.1. Let $S' \rightarrow S$ be the blowup in \mathcal{I} and let $E \subset S'$ be the exceptional divisor (Divisors, Lemma 30.18.4). Then we see that we've reduced the problem to the case where there exists an effective Cartier divisor $D \subset S$ whose support is $X \setminus U$. In particular we may assume U is scheme theoretically dense in S (Divisors, Lemma 30.9.4).

Suppose that P is local on S : If $S = \bigcup S_i$ is a finite open covering by quasi-compact opens and P holds for $\mathcal{F}_{S_i}/X_{S_i}/S_i$ then P holds for $\mathcal{F}/X/S$. In this case the general problem above is local on S as well, i.e., if given $s \in S$ we can find a quasi-compact open neighbourhood W of s such that the problem for $\mathcal{F}_W/X_W/W$ is solvable, then the problem is solvable for $\mathcal{F}/X/S$. This follows from Divisors, Lemmas 30.20.3 and 30.20.4.

Lemma 37.27.2. *Let R be a local ring. Let M be a finite R -module. Let $k \geq 0$. Assume that $\text{Fit}_k(M) = (f)$ for some $f \in R$. Let M' be the quotient of M by $\{x \in M \mid fx = 0\}$. Then M' can be generated by k elements.*

Proof. Choose generators $x_1, \dots, x_n \in M$ corresponding to the surjection $R^{\oplus n} \rightarrow M$. Since R is local if a set of elements $E \subset (f)$ generates (f) , then some $e \in E$ generates (f) , see Algebra, Lemma 10.19.1. Hence we may pick z_1, \dots, z_{n-k} in the kernel of $R^{\oplus n} \rightarrow M$ such that some $(n-k) \times (n-k)$ minor of the $n \times (n-k)$ matrix $A = (z_{ij})$ is (f) . After renumbering the x_i we may assume the first minor $\det(z_{ij})_{1 \leq i, j \leq n-k}$ generates (f) , i.e., $\det(z_{ij})_{1 \leq i, j \leq n-k} = uf$ for some unit $u \in R$. Every other minor is a multiple of f . By Algebra, Lemma 10.14.5 there exists a

$n - k \times n - k$ matrix B such that

$$AB = f \begin{pmatrix} u1_{n-k \times n-k} \\ C \end{pmatrix}$$

for some matrix C with coefficients in R . This implies that for every $i \leq n - k$ the element $y_i = ux_i + \sum_j c_{ji}x_j$ is annihilated by f . Since $M/\sum Ry_i$ is generated by the images of x_{n-k+1}, \dots, x_n we win. \square

Lemma 37.27.3. *Let R be a ring and let $f \in R$. Let $r, d \geq 0$ be integers. Let $R \rightarrow S$ be a ring map and let M be an S -module. Assume*

- (1) $R \rightarrow S$ is of finite presentation and flat,
- (2) every fibre ring $S \otimes_R \kappa(\mathfrak{p})$ is geometrically integral over R ,
- (3) M is a finite S -module,
- (4) M_f is a finitely presented S_f -module,
- (5) for all $\mathfrak{p} \in R$, $f \notin \mathfrak{p}$ with $\mathfrak{q} = \mathfrak{p}S$ the module $M_{\mathfrak{q}}$ is free of rank r over $S_{\mathfrak{q}}$.

Then there exists a finitely generated ideal $I \subset R$ with $V(f) = V(I)$ such that for all $a \in I$ with $R' = R[\frac{I}{a}]$ the quotient

$$M' = (M \otimes_R R')/a\text{-power torsion}$$

over $S' = S \otimes_R R'$ satisfies the following: for every prime $\mathfrak{p}' \subset R'$ there exists a $g \in S'$, $g \notin \mathfrak{p}'S'$ such that M'_g is a free S'_g -module of rank r .

Proof. Choose a surjection $S^{\oplus n} \rightarrow M$, which is possible by (1). Choose a finite submodule $K \subset \text{Ker}(S^{\oplus n} \rightarrow M)$ such that $S^{\oplus n}/K \rightarrow M$ becomes an isomorphism after inverting f . This is possible by (2). Set $M_1 = S^{\oplus n}/K$ and suppose we can prove the lemma for M_1 . Say $I \subset R$ is the corresponding ideal. Then for $a \in I$ the map

$$M'_1 = (M_1 \otimes_R R')/a\text{-power torsion} \longrightarrow M' = (M \otimes_R R')/a\text{-power torsion}$$

is surjective. It is also an isomorphism after inverting a in R' as $R'_a = R_f$, see Algebra, Lemma 10.56.3. But a is a nonzerodivisor on M'_1 , whence the displayed map is an isomorphism. Thus it suffices to prove the lemma in case M is a finitely presented S -module.

Assume M is a finitely presented S -module satisfying (3). Then $J = \text{Fit}_r(M) \subset S$ is a finitely generated ideal. By Lemma 37.9.3 we can write S as a direct summand of a free R -module: $\bigoplus_{\alpha \in A} R = S \oplus C$. For any element $h \in S$ writing $h = \sum a_{\alpha}$ in the decomposition above, we say that the a_{α} are the coefficients of h . Let $I' \subset R$ be the ideal generated by the coefficients of the elements of J . Multiplication by an element of S defines an R -linear map $S \rightarrow S$, hence I' is generated by the coefficients of the generators of J , i.e., I' is a finitely generated ideal. We claim that $I = fI'$ works.

We first check that $V(f) = V(I)$. The inclusion $V(f) \subset V(I)$ is clear. Conversely, if $f \notin \mathfrak{p}$, then $\mathfrak{q} = \mathfrak{p}S$ is not an element of $V(J)$ by property (3) and the fact that formation of fitting ideals commute with base change (More on Algebra, Lemma 15.5.4). Hence there is an element of J which does not map to zero in $S \otimes_R \kappa(\mathfrak{p})$. Thus there exists an element of I' which is not contained in \mathfrak{p} , so $\mathfrak{p} \notin V(fI') = V(I)$.

Let $a \in I$ and let $\mathfrak{p}' \subset R' = R[\frac{I}{a}]$ be a prime ideal. Set $S' = S \otimes_S R'$ and $\mathfrak{q}' = \mathfrak{p}'S'$. Every element g of $JS' = \text{Fit}_r(M \otimes_S S')$ can be written as $g = \sum_{\alpha} c_{\alpha}$ for some $c_{\alpha} \in IS'$. Since $IR' = aR'$ we can write $c_{\alpha} = ac'_{\alpha}$ for some $c'_{\alpha} \in R'$ and

$g = (\sum c'_\alpha) a = g' a$ in S' . Moreover, we can find some $g_0 \in JS'$ such that $a = c_\alpha$ for some α . For this element $g_0 = g'_0 a$ where g'_0 is a unit in $S'_{\mathfrak{q}'}$. Thus we see that $JS'_{\mathfrak{q}'}$ is the principal ideal generated by the nonzerodivisor a . It follows from Lemma 37.27.2 that $M'_{\mathfrak{q}'}$ can be generated by r elements. Since M' is finite, there exist $m_1, \dots, m_r \in M'$ and $g \in S', g \notin \mathfrak{q}'$ such that the corresponding map $(S')^{\oplus r} \rightarrow M'$ becomes surjective after inverting g .

Finally, consider the finitely generated ideal $J' = \text{Fit}_{k-1}(M')$. Note that $J'S'_g$ is generated by the coefficients of relations between m_1, \dots, m_r (compatibility of fitting ideal with base change). Thus it suffices to show that $J' = 0$, see More on Algebra, Lemma 15.5.7. Since $R'_a = R_f$ (see above) and $M'_a = M_f$ we see from (3) that J'_a maps to zero in $S_{\mathfrak{q}''}$ for any prime $\mathfrak{q}'' \subset S'$ of the form $\mathfrak{q}'' = \mathfrak{p}'' S'$ where $\mathfrak{p}'' \subset R'_a$. Since $S'_a \subset \prod_{\mathfrak{q}'' \text{ as above}} S'_{\mathfrak{q}''}$ (as $(S'_a)_{\mathfrak{p}''} \subset S'_{\mathfrak{q}''}$ by Lemma 37.7.4) we see that $J'R'_a = 0$. Since a is a nonzerodivisor in R' we conclude that $J' = 0$ and we win. \square

Lemma 37.27.4. *Let S be a quasi-compact and quasi-separated scheme. Let $X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent module on X . Let $U \subset S$ be a quasi-compact open. Assume*

- (1) $X \rightarrow S$ is affine, of finite presentation, flat, geometrically integral fibres,
- (2) \mathcal{F} is a module of finite type,
- (3) \mathcal{F}_U is of finite presentation,
- (4) \mathcal{F} is flat over S at all generic points of fibres lying over points of U .

Then there exists a U -admissible blowup $S' \rightarrow S$ and an open subscheme $V \subset X_{S'}$ such that (a) the strict transform \mathcal{F}' of \mathcal{F} restricts to a finitely locally free \mathcal{O}_V -module and (b) $V \rightarrow S'$ is surjective.

Proof. Given $\mathcal{F}/X/S$ and $U \subset S$ with hypotheses as in the lemma, denote P the property “ \mathcal{F} is flat over S at all generic points of fibres”. It is clear that P is preserved under strict transform, see Divisors, Lemma 30.19.3 and Morphisms, Lemma 28.26.6. It is also clear that P is local on S . Hence any and all observations of Remark 37.27.1 apply to the problem posed by the lemma.

Consider the function $r : U \rightarrow \mathbf{Z}_{\geq 0}$ which assigns to $u \in U$ the integer

$$r(u) = \dim_{\kappa(\xi_u)}(\mathcal{F}_{\xi_u} \otimes \kappa(\xi_u))$$

where ξ_u is the generic point of the fibre X_u . By More on Morphisms, Lemma 36.13.7 and the fact that the image of an open in X_S in S is open, we see that $r(u)$ is locally constant. Accordingly $U = U_0 \amalg U_1 \amalg \dots \amalg U_c$ is a finite disjoint union of open and closed subschemes where r is constant with value i on U_i . By Divisors, Lemma 30.20.5 we can find a U -admissible blowup to decompose S into the disjoint union of two schemes, the first containing U_0 and the second $U_1 \cup \dots \cup U_c$. Repeating this $c-1$ more times we may assume that S is a disjoint union $S = S_0 \amalg S_1 \amalg \dots \amalg S_c$ with $U_i \subset S_i$. Thus we may assume the function r defined above is constant, say with value r .

By Remark 37.27.1 we see that we may assume that we have an effective Cartier divisor $D \subset S$ whose support is $S \setminus U$. Another application of Remark 37.27.1 combined with Divisors, Lemma 30.9.2 tells us we may assume that $S = \text{Spec}(R)$ and $D = \text{Spec}(R/(f))$ for some nonzerodivisor $f \in R$. This case is handled by Lemma 37.27.3. \square

Lemma 37.27.5. *Let $A \rightarrow C$ be a finite locally free ring map of rank d . Let $h \in C$ be an element such that C_h is étale over A . Let $J \subset C$ be an ideal. Set $I = \text{Fit}_0(C/J)$ where we think of C/J as a finite A -module. Then $IC_h = JJ'$ for some ideal $J' \subset C_h$. If J is finitely generated so are I and J' .*

Proof. We will use basic properties of fitting ideals, see More on Algebra, Lemma 15.5.4. Then IC is the fitting ideal of $C/J \otimes_A C$. Note that $C \rightarrow C \otimes_A C$, $c \mapsto 1 \otimes c$ has a section (the multiplication map). By assumption $C \rightarrow C \otimes_A C$ is étale at every prime in the image of $\text{Spec}(C_h)$ under this section. Hence the multiplication map $C \otimes_A C_h \rightarrow C_h$ is étale in particular flat, see Algebra, Lemma 10.138.9. Hence there exists a C_h -algebra such that $C \otimes_A C_h \cong C_h \oplus C'$ as C_h -algebras, see Algebra, Lemma 10.138.10. Thus $(C/J) \otimes_A C_h \cong (C_h/J_h) \oplus C'/I'$ as C_h -modules for some ideal $I' \subset C'$. Hence $IC_h = JJ'$ with $J' = \text{Fit}_0(C'/I')$ where we view C'/I' as a C_h -module. \square

Lemma 37.27.6. *Let $A \rightarrow B$ be an étale ring map. Let $a \in A$ be a nonzerodivisor. Let $J \subset B$ be a finite type ideal with $V(J) \subset V(aB)$. For every $\mathfrak{q} \subset B$ there exists a finite type ideal $I \subset A$ with $V(I) \subset V(a)$ and $g \in B$, $g \notin \mathfrak{q}$ such that $IB_g = JJ'$ for some finite type ideal $J' \subset B_g$.*

Proof. We may replace B by a principal localization at an element $g \in B$, $g \notin \mathfrak{q}$. Thus we may assume that B is standard étale, see Algebra, Proposition 10.138.17. Thus we may assume B is a localization of $C = A[x]/(f)$ for some monic $f \in A[x]$ of some degree d . Say $B = C_h$ for some $h \in C$. Choose elements $h_1, \dots, h_n \in C$ which generate J over B . The condition $V(J) \subset V(aB)$ signifies that $a^m = \sum b_i h_i$ in B for some large m . Set $h_{n+1} = a^m$. As in Lemma 37.27.5 we take $I = \text{Fit}_0(C/(h_1, \dots, h_{r+1}))$. Since the module $C/(h_1, \dots, h_{r+1})$ is annihilated by a^m we see that $a^{dm} \in I$ which implies that $V(I) \subset V(a)$. \square

Lemma 37.27.7. *Let S be a quasi-compact and quasi-separated scheme. Let $X \rightarrow S$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent module on X . Let $U \subset S$ be a quasi-compact open. Assume there exist finitely many commutative diagrams*

$$\begin{array}{ccc} X_i & \xrightarrow{\quad} & X \\ \downarrow & \searrow^{j_i} & \downarrow \\ S_i^* & \longrightarrow & S_i \xrightarrow{e_i} S \end{array}$$

where

- (1) $e_i : S_i \rightarrow S$ are quasi-compact étale morphisms and $S = \bigcup e_i(S_i)$,
- (2) $j_i : X_i \rightarrow X$ are étale morphisms and $X = \bigcup j_i(X_i)$,
- (3) $S_i^* \rightarrow S_i$ is an $e_i^{-1}(U)$ -admissible blowup such that the strict transform \mathcal{F}_i^* of $j_i^* \mathcal{F}$ is flat over S_i^* .

Then there exists a U -admissible blowup $S' \rightarrow S$ such that the strict transform of \mathcal{F} is flat over S' .

Proof. We claim that the hypotheses of the lemma are preserved under U -admissible blowups. Namely, suppose $b : S' \rightarrow S$ is a U -admissible blowup in the quasi-coherent sheaf of ideals \mathcal{I} . Moreover, let $S'_i \rightarrow S_i$ be the blowup in the quasi-coherent sheaf of ideals \mathcal{J}_i . Then the collection of morphisms $e'_i : S'_i = S_i \times_S S' \rightarrow S'$ and $j'_i : X'_i = X_i \times_S S' \rightarrow X \times_S S'$ satisfy conditions (1), (2), (3) for the strict transform \mathcal{F}' of \mathcal{F} relative to the blowup $S' \rightarrow S$. First, observe that S'_i is the

blowup of S_i in the pullback of \mathcal{I} , see Divisors, Lemma 30.18.3. Second, consider the blowup $S_i'^* \rightarrow S_i'$ of S_i' in the pullback of the ideal \mathcal{J}_i . By Divisors, Lemma 30.18.10 we get a commutative diagram

$$\begin{array}{ccc} S_i'^* & \longrightarrow & S_i' \\ \downarrow & \searrow & \downarrow \\ S_i^* & \longrightarrow & S_i \end{array}$$

and all the morphisms in the diagram above are blowups. Hence by Divisors, Lemmas 30.19.3 and 30.19.6 we see

$$\begin{aligned} & \text{the strict transform of } (j_i')^* \mathcal{F}' \text{ under } S_i'^* \rightarrow S_i' \\ &= \text{the strict transform of } j_i^* \mathcal{F} \text{ under } S_i'^* \rightarrow S_i \\ &= \text{the strict transform of } \mathcal{F}'_i \text{ under } S_i'^* \rightarrow S_i' \\ &= \text{the pullback of } \mathcal{F}_i^* \text{ via } X_i \times_{S_i} S_i'^* \rightarrow X_i \end{aligned}$$

which is therefore flat over $S_i'^*$ (Morphisms, Lemma 28.26.6). Having said this, we see that all observations of Remark 37.27.1 apply to the problem of finding a U -admissible blowup such that the strict transform of \mathcal{F} becomes flat over the base under assumptions as in the lemma. In particular, we may assume that $S \setminus U$ is the support of an effective Cartier divisor $D \subset S$. Another application of Remark 37.27.1 combined with Divisors, Lemma 30.9.2 shows we may assume that $S = \text{Spec}(A)$ and $D = \text{Spec}(A/(a))$ for some nonzerodivisor $a \in A$.

Pick an i and $s \in S_i$. Lemma 37.27.6 implies we can find an open neighbourhood $s \in W_i \subset S_i$ and a finite type quasi-coherent ideal $\mathcal{I} \subset \mathcal{O}_S$ such that $\mathcal{I} \cdot \mathcal{O}_{W_i} = \mathcal{J}_i \mathcal{J}_i'$ for some finite type quasi-coherent ideal $\mathcal{J}_i' \subset \mathcal{O}_{W_i}$ and such that $V(\mathcal{I}) \subset V(a) = S \setminus U$. Since S_i is quasi-compact we can replace S_i by a finite collection W_1, \dots, W_n of these opens and assume that for each i there exists a quasi-coherent sheaf of ideals $\mathcal{I}_i \subset \mathcal{O}_S$ such that $\mathcal{I}_i \cdot \mathcal{O}_{S_i} = \mathcal{J}_i \mathcal{J}_i'$ for some finite type quasi-coherent ideal $\mathcal{J}_i' \subset \mathcal{O}_{S_i}$. As in the discussion of the first paragraph of the proof, consider the blowup S' of S in the product $\mathcal{I}_1 \dots \mathcal{I}_n$ (this blowup is U -admissible by construction). The base change of $S' \rightarrow S$ to S_i is the blowup in

$$\mathcal{J}_i \cdot \mathcal{J}_i' \mathcal{I}_1 \dots \hat{\mathcal{I}}_i \dots \mathcal{I}_n$$

which factors through the given blowup $S_i^* \rightarrow S_i$ (Divisors, Lemma 30.18.10). In the notation of the diagram above this means that $S_i'^* = S_i'$. Hence after replacing S by S' we arrive in the situation that $j_i^* \mathcal{F}$ is flat over S_i . Hence $j_i^* \mathcal{F}$ is flat over S , see Lemma 37.2.3. By Morphisms, Lemma 28.26.11 we see that \mathcal{F} is flat over S . \square

Theorem 37.27.8. *Let S be a quasi-compact and quasi-separated scheme. Let X be a scheme over S . Let \mathcal{F} be a quasi-coherent module on X . Let $U \subset S$ be a quasi-compact open. Assume*

- (1) X is quasi-compact,
- (2) X is locally of finite presentation over S ,
- (3) \mathcal{F} is a module of finite type,
- (4) \mathcal{F}_U is of finite presentation, and
- (5) \mathcal{F}_U is flat over U .

Then there exists a U -admissible blowup $S' \rightarrow S$ such that the strict transform \mathcal{F}' of \mathcal{F} is an $\mathcal{O}_{X \times_S S'}$ -module of finite presentation and flat over S' .

Proof. We first prove that we can find a U -admissible blowup such that the strict transform is flat. The question is étale local on the source and the target, see Lemma 37.27.7 for a precise statement. In particular, we may assume that $S = \text{Spec}(R)$ and $X = \text{Spec}(A)$ are affine. For $s \in S$ write $\mathcal{F}_s = \mathcal{F}|_{X_s}$ (pullback of \mathcal{F} to the fibre). As $X \rightarrow S$ is of finite type $d = \max_{s \in S} \dim(\text{Supp}(\mathcal{F}_s))$ is an integer. We will do induction on d .

Let $x \in X$ be a point of X lying over $s \in S$ with $\dim_x(\text{Supp}(\mathcal{F}_s)) = d$. Apply Lemma 37.3.2 to get $g : X' \rightarrow X$, $e : S' \rightarrow S$, $i : Z' \rightarrow X'$, and $\pi : Z' \rightarrow Y'$. Observe that $Y' \rightarrow S'$ is a smooth morphism of affines with geometrically irreducible fibres of dimension d . Because the problem is étale local it suffices to prove the theorem for $g^*\mathcal{F}/X'/S'$. Because $i : Z' \rightarrow X'$ is a closed immersion of finite presentation (and since strict transform commutes with affine pushforward, see Divisors, Lemma 30.19.4) it suffices to prove the flattening result for \mathcal{G} . Since π is finite (hence also affine) it suffices to prove the flattening result for $\pi_*\mathcal{G}/Y'/S'$. Thus we may assume that $X \rightarrow S$ is a smooth morphism of affines with geometrically irreducible fibres of dimension d .

Next, we apply a blow up as in Lemma 37.27.4. Doing so we reach the situation where there exists an open $V \subset X$ surjecting onto S such that $\mathcal{F}|_V$ is finite locally free. Let $\xi \in X$ be the generic point of X_s . Let $r = \dim_{\kappa(\xi)} \mathcal{F}_\xi \otimes \kappa(\xi)$. Choose a map $\alpha : \mathcal{O}_X^{\oplus r} \rightarrow \mathcal{F}$ which induces an isomorphism $\kappa(\xi)^{\oplus r} \rightarrow \mathcal{F}_\xi \otimes \kappa(\xi)$. Because \mathcal{F} is locally free over V we find an open neighbourhood W of ξ where α is an isomorphism. Shrink S to an affine open neighbourhood of s such that $W \rightarrow S$ is surjective. Say \mathcal{F} is the quasi-coherent module associated to the A -module N . Since \mathcal{F} is flat over S at all generic points of fibres (in fact at all points of W), we see that

$$\alpha_{\mathfrak{p}} : A_{\mathfrak{p}}^{\oplus r} \rightarrow N_{\mathfrak{p}}$$

is universally injective for all primes \mathfrak{p} of R , see Lemma 37.10.1. Hence α is universally injective, see Algebra, Lemma 10.79.12. Set $\mathcal{H} = \text{Coker}(\alpha)$. By Divisors, Lemma 30.19.7 we see that, given a U -admissible blowup $S' \rightarrow S$ the strict transforms of \mathcal{F}' and \mathcal{H}' fit into an exact sequence

$$0 \rightarrow \mathcal{O}_{X \times_S S'}^{\oplus r} \rightarrow \mathcal{F}' \rightarrow \mathcal{H}' \rightarrow 0$$

Hence Lemma 37.10.1 also shows that \mathcal{F}' is flat at a point x' if and only if \mathcal{H}' is flat at that point. In particular \mathcal{H}_U is flat over U and \mathcal{H}_U is a module of finite presentation. We may apply the induction hypothesis to \mathcal{H} to see that there exists a U -admissible blowup such that the strict transform \mathcal{H}' is flat as desired.

To finish the proof of the theorem we still have to show that \mathcal{F}' is a module of finite presentation (after possibly another U -admissible blowup). This follows from Lemma 37.10.11 as we can assume $U \subset S$ is scheme theoretically dense (see third paragraph of Remark 37.27.1). This finishes the proof of the theorem. \square

37.28. Applications

In this section we apply some of the results above.

Lemma 37.28.1. *Let S be a quasi-compact and quasi-separated scheme. Let X be a scheme over S . Let $U \subset S$ be a quasi-compact open. Assume*

- (1) $X \rightarrow S$ is of finite type and quasi-separated, and
- (2) $X_U \rightarrow U$ is flat and locally of finite presentation.

Then there exists a U -admissible blowup $S' \rightarrow S$ such that the strict transform of X is flat and of finite presentation over S' .

Proof. Since $X \rightarrow S$ is quasi-compact and quasi-separated by assumption, the strict transform of X with respect to a blowing up $S' \rightarrow S$ is also quasi-compact and quasi-separated. Hence to prove the lemma it suffices to find a U -admissible blowup such that the strict transform is flat and locally of finite presentation. Let $X = W_1 \cup \dots \cup W_n$ be a finite affine open covering. If we can find a U -admissible blowup $S_i \rightarrow S$ such that the strict transform of W_i is flat and locally of finite presentation, then there exists a U -admissible blowing up $S' \rightarrow S$ dominating all $S_i \rightarrow S$ which does the job (see Divisors, Lemma 30.20.4; see also Remark 37.27.1). Hence we may assume X is affine.

Assume X is affine. By Morphisms, Lemma 28.40.2 we can choose an immersion $j : X \rightarrow \mathbf{A}_S^n$ over S . Let $V \subset \mathbf{A}_S^n$ be a quasi-compact open subscheme such that j induces a closed immersion $i : X \rightarrow V$ over S . Apply Theorem 37.27.8 to $V \rightarrow S$ and the quasi-coherent module $i_*\mathcal{O}_X$ to obtain a U -admissible blowup $S' \rightarrow S$ such that the strict transform of $i_*\mathcal{O}_X$ is flat over S' and of finite presentation over $\mathcal{O}_{V \times_S S'}$. Let X' be the strict transform of X with respect to $S' \rightarrow S$. Let $i' : X' \rightarrow V \times_S S'$ be the induced morphism. Since taking strict transform commutes with pushforward along affine morphisms (Divisors, Lemma 30.19.4), we see that $i'_*\mathcal{O}_{X'}$ is flat over S and of finite presentation as a $\mathcal{O}_{V \times_S S'}$ -module. This implies the lemma. \square

Lemma 37.28.2. *Let $\varphi : X \rightarrow S$ be a separated morphism of finite type with S quasi-compact and quasi-separated. Let $U \subset S$ be a quasi-compact open such that $\varphi^{-1}U \rightarrow U$ is an isomorphism. Then there exists a U -admissible blowup $S' \rightarrow S$ such that the strict transform X' of X is isomorphic to an open subscheme of S' .*

Proof. The discussion in Remark 37.27.1 applies. Thus we may do a first U -admissible blowup and assume the complement $S \setminus U$ is the support of an effective Cartier divisor D . In particular U is scheme theoretically dense in S . Next, we do another U -admissible blowup to get to the situation where $X \rightarrow S$ is flat and of finite presentation, see Lemma 37.28.1. In this case the result follows from More on Morphisms, Lemma 36.31.4. \square

The following lemma says that a proper modification can be dominated by a blowup.

Lemma 37.28.3. *Let $\varphi : X \rightarrow S$ be a proper morphism with S quasi-compact and quasi-separated. Let $U \subset S$ be a quasi-compact open such that $\varphi^{-1}U \rightarrow U$ is an isomorphism. Then there exists a U -admissible blowup $S' \rightarrow S$ which dominates X , i.e., such that there exists a factorization $S' \rightarrow X \rightarrow S$ of the blowup morphism.*

Proof. The discussion in Remark 37.27.1 applies. Thus we may do a first U -admissible blowup and assume the complement $S \setminus U$ is the support of an effective Cartier divisor D . In particular U is scheme theoretically dense in S . Choose another U -admissible blowup $S' \rightarrow S$ such that the strict transform X' of X is an

open subscheme of S' , see Lemma 37.28.2. Since $X' \rightarrow S'$ is proper, and $U \subset S'$ is dense, we see that $X' = S'$. Some details omitted. \square

Groupoid Schemes

38.1. Introduction

This chapter is devoted to generalities concerning groupoid schemes. See for example the beautiful paper [KM97] by Keel and Mori.

38.2. Notation

Let S be a scheme. If U, T are schemes over S we denote $U(T)$ for the set of T -valued points of U over S . In a formula: $U(T) = \text{Mor}_S(T, U)$. We try to reserve the letter T to denote a “test scheme” over S , as in the discussion that follows. Suppose we are given schemes X, Y over S and a morphism of schemes $f : X \rightarrow Y$ over S . For any scheme T over S we get an induced map of sets

$$f : X(T) \longrightarrow Y(T)$$

which as indicated we denote by f also. In fact this construction is functorial in the scheme T/S . Yoneda’s Lemma, see Categories, Lemma 4.3.5, says that f determines and is determined by this transformation of functors $f : h_X \rightarrow h_Y$. More generally, we use the same notation for maps between fibre products. For example, if X, Y, Z are schemes over S , and if $m : X \times_S Y \rightarrow Z \times_S Z$ is a morphism of schemes over S , then we think of m as corresponding to a collection of maps between T -valued points

$$X(T) \times Y(T) \longrightarrow Z(T) \times Z(T).$$

And so on and so forth.

We continue our convention to label projection maps starting with index 0, so we have $\text{pr}_0 : X \times_S Y \rightarrow X$ and $\text{pr}_1 : X \times_S Y \rightarrow Y$.

38.3. Equivalence relations

Recall that a *relation* R on a set A is just a subset of $R \subset A \times A$. We usually write aRb to indicate $(a, b) \in R$. We say the relation is *transitive* if $aRb, bRc \Rightarrow aRc$. We say the relation is *reflexive* if aRa for all $a \in A$. We say the relation is *symmetric* if $aRb \Rightarrow bRa$. A relation is called an *equivalence relation* if it is transitive, reflexive and symmetric.

In the setting of schemes we are going to relax the notion of a relation a little bit and just require $R \rightarrow A \times A$ to be a map. Here is the definition.

Definition 38.3.1. Let S be a scheme. Let U be a scheme over S .

- (1) A *pre-relation* on U over S is any morphism $j : R \rightarrow U \times_S U$. In this case we set $t = \text{pr}_0 \circ j$ and $s = \text{pr}_1 \circ j$, so that $j = (t, s)$.
- (2) A *relation* on U over S is a monomorphism $j : R \rightarrow U \times_S U$.

- (3) A *pre-equivalence relation* is a pre-relation $j : R \rightarrow U \times_S U$ such that the image of $j : R(T) \rightarrow U(T) \times U(T)$ is an equivalence relation for all T/S .
- (4) We say a morphism $R \rightarrow U \times_S U$ is an *equivalence relation on U over S* if and only if for every T/S the T -valued points of R define an equivalence relation on the set of T -valued points of U .

In other words, an equivalence relation is a pre-equivalence relation such that j is a relation.

Lemma 38.3.2. *Let S be a scheme. Let U be a scheme over S . Let $j : R \rightarrow U \times_S U$ be a pre-relation. Let $g : U' \rightarrow U$ be a morphism of schemes. Finally, set*

$$R' = (U' \times_S U') \times_{U \times_S U} R \xrightarrow{j'} U' \times_S U'$$

Then j' is a pre-relation on U' over S . If j is a relation, then j' is a relation. If j is a pre-equivalence relation, then j' is a pre-equivalence relation. If j is an equivalence relation, then j' is an equivalence relation.

Proof. Omitted. □

Definition 38.3.3. Let S be a scheme. Let U be a scheme over S . Let $j : R \rightarrow U \times_S U$ be a pre-relation. Let $g : U' \rightarrow U$ be a morphism of schemes. The pre-relation $j' : R' \rightarrow U' \times_S U'$ is called the *restriction*, or *pullback* of the pre-relation j to U' . In this situation we sometimes write $R' = R|_{U'}$.

Lemma 38.3.4. *Let $j : R \rightarrow U \times_S U$ be a pre-relation. Consider the relation on points of the scheme U defined by the rule*

$$x \sim y \Leftrightarrow \exists r \in R : t(r) = x, s(r) = y.$$

If j is a pre-equivalence relation then this is an equivalence relation.

Proof. Suppose that $x \sim y$ and $y \sim z$. Pick $r \in R$ with $t(r) = x$, $s(r) = y$ and pick $r' \in R$ with $t(r') = y$, $s(r') = z$. Pick a field K fitting into the following commutative diagram

$$\begin{array}{ccc} \kappa(r) & \longrightarrow & K \\ \uparrow & & \uparrow \\ \kappa(y) & \longrightarrow & \kappa(r') \end{array}$$

Denote $x_K, y_K, z_K : \text{Spec}(K) \rightarrow U$ the morphisms

$$\begin{array}{l} \text{Spec}(K) \rightarrow \text{Spec}(\kappa(r)) \rightarrow \text{Spec}(\kappa(x)) \rightarrow U \\ \text{Spec}(K) \rightarrow \text{Spec}(\kappa(r)) \rightarrow \text{Spec}(\kappa(y)) \rightarrow U \\ \text{Spec}(K) \rightarrow \text{Spec}(\kappa(r')) \rightarrow \text{Spec}(\kappa(z)) \rightarrow U \end{array}$$

By construction $(x_K, y_K) \in j(R(K))$ and $(y_K, z_K) \in j(R(K))$. Since j is a pre-equivalence relation we see that also $(x_K, z_K) \in j(R(K))$. This clearly implies that $x \sim z$.

The proof that \sim is reflexive and symmetric is omitted. □

38.4. Group schemes

Let us recall that a *group* is a pair (G, m) where G is a set, and $m : G \times G \rightarrow G$ is a map of sets with the following properties:

- (1) (associativity) $m(g, m(g', g'')) = m(m(g, g'), g'')$ for all $g, g', g'' \in G$,
- (2) (identity) there exists a unique element $e \in G$ (called the *identity*, *unit*, or 1 of G) such that $m(g, e) = m(e, g) = g$ for all $g \in G$, and
- (3) (inverse) for all $g \in G$ there exists a $i(g) \in G$ such that $m(g, i(g)) = m(i(g), g) = e$, where e is the identity.

Thus we obtain a map $e : \{*\} \rightarrow G$ and a map $i : G \rightarrow G$ so that the quadruple (G, m, e, i) satisfies the axioms listed above.

A *homomorphism of groups* $\psi : (G, m) \rightarrow (G', m')$ is a map of sets $\psi : G \rightarrow G'$ such that $m'(\psi(g), \psi(g')) = \psi(m(g, g'))$. This automatically insures that $\psi(e) = e'$ and $i'(\psi(g)) = \psi(i(g))$. (Obvious notation.) We will use this below.

Definition 38.4.1. Let S be a scheme.

- (1) A *group scheme over S* is a pair (G, m) , where G is a scheme over S and $m : G \times_S G \rightarrow G$ is a morphism of schemes over S with the following property: For every scheme T over S the pair $(G(T), m)$ is a group.
- (2) A *morphism $\psi : (G, m) \rightarrow (G', m')$ of group schemes over S* is a morphism $\psi : G \rightarrow G'$ of schemes over S such that for every T/S the induced map $\psi : G(T) \rightarrow G'(T)$ is a homomorphism of groups.

Let (G, m) be a group scheme over the scheme S . By the discussion above (and the discussion in Section 38.2) we obtain morphisms of schemes over S : (identity) $e : S \rightarrow G$ and (inverse) $i : G \rightarrow G$ such that for every T the quadruple $(G(T), m, e, i)$ satisfies the axioms of a group listed above.

Let $(G, m), (G', m')$ be group schemes over S . Let $f : G \rightarrow G'$ be a morphism of schemes over S . It follows from the definition that f is a morphism of group schemes over S if and only if the following diagram is commutative:

$$\begin{array}{ccc} G \times_S G & \xrightarrow{f \times f} & G' \times_S G' \\ m \downarrow & & \downarrow m \\ G & \xrightarrow{f} & G' \end{array}$$

Lemma 38.4.2. Let (G, m) be a group scheme over S . Let $S' \rightarrow S$ be a morphism of schemes. The pullback $(G_{S'}, m_{S'})$ is a group scheme over S' .

Proof. Omitted. □

Definition 38.4.3. Let S be a scheme. Let (G, m) be a group scheme over S .

- (1) A *closed subgroup scheme* of G is a closed subscheme $H \subset G$ such that $m|_{H \times_S H}$ factors through H and induces a group scheme structure on H over S .
- (2) An *open subgroup scheme* of G is an open subscheme $G' \subset G$ such that $m|_{G' \times_S G'}$ factors through G' and induces a group scheme structure on G' over S .

Alternatively, we could say that H is a closed subgroup scheme of G if it is a group scheme over S endowed with a morphism of group schemes $i : H \rightarrow G$ over S which identifies H with a closed subscheme of G .

Definition 38.4.4. Let S be a scheme. Let (G, m) be a group scheme over S .

- (1) We say G is a *smooth group scheme* if the structure morphism $G \rightarrow S$ is smooth.
- (2) We say G is a *flat group scheme* if the structure morphism $G \rightarrow S$ is flat.
- (3) We say G is a *separated group scheme* if the structure morphism $G \rightarrow S$ is separated.

Add more as needed.

38.5. Examples of group schemes

Example 38.5.1 (Multiplicative group scheme). Consider the functor which associates to any scheme T the group $\Gamma(T, \mathcal{O}_T^*)$ of units in the global sections of the structure sheaf. This is representable by the scheme

$$\mathbf{G}_m = \text{Spec}(\mathbf{Z}[x, x^{-1}])$$

The morphism giving the group structure is the morphism

$$\begin{array}{ccc} \mathbf{G}_m \times \mathbf{G}_m & \rightarrow & \mathbf{G}_m \\ \text{Spec}(\mathbf{Z}[x, x^{-1}] \otimes_{\mathbf{Z}} \mathbf{Z}[x, x^{-1}]) & \rightarrow & \text{Spec}(\mathbf{Z}[x, x^{-1}]) \\ \mathbf{Z}[x, x^{-1}] \otimes_{\mathbf{Z}} \mathbf{Z}[x, x^{-1}] & \leftarrow & \mathbf{Z}[x, x^{-1}] \\ x \otimes x & \leftarrow & x \end{array}$$

Hence we see that \mathbf{G}_m is a group scheme over \mathbf{Z} . For any scheme S the base change $\mathbf{G}_{m,S}$ is a group scheme over S whose functor of points is

$$T/S \mapsto \mathbf{G}_{m,S}(T) = \mathbf{G}_m(T) = \Gamma(T, \mathcal{O}_T^*)$$

as before.

Example 38.5.2 (Roots of unity). Let $n \in \mathbf{N}$. Consider the functor which associates to any scheme T the subgroup of $\Gamma(T, \mathcal{O}_T^*)$ consisting of n th roots of unity. This is representable by the scheme

$$\mu_n = \text{Spec}(\mathbf{Z}[x]/(x^n - 1)).$$

The morphism giving the group structure is the morphism

$$\begin{array}{ccc} \mu_n \times \mu_n & \rightarrow & \mu_n \\ \text{Spec}(\mathbf{Z}[x]/(x^n - 1) \otimes_{\mathbf{Z}} \mathbf{Z}[x]/(x^n - 1)) & \rightarrow & \text{Spec}(\mathbf{Z}[x]/(x^n - 1)) \\ \mathbf{Z}[x]/(x^n - 1) \otimes_{\mathbf{Z}} \mathbf{Z}[x]/(x^n - 1) & \leftarrow & \mathbf{Z}[x]/(x^n - 1) \\ x \otimes x & \leftarrow & x \end{array}$$

Hence we see that μ_n is a group scheme over \mathbf{Z} . For any scheme S the base change $\mu_{n,S}$ is a group scheme over S whose functor of points is

$$T/S \mapsto \mu_{n,S}(T) = \mu_n(T) = \{f \in \Gamma(T, \mathcal{O}_T^*) \mid f^n = 1\}$$

as before.

Example 38.5.3 (Additive group scheme). Consider the functor which associates to any scheme T the group $\Gamma(T, \mathcal{O}_T)$ of global sections of the structure sheaf. This is representable by the scheme

$$\mathbf{G}_a = \text{Spec}(\mathbf{Z}[x])$$

The morphism giving the group structure is the morphism

$$\begin{aligned} \mathbf{G}_a \times \mathbf{G}_a &\rightarrow \mathbf{G}_a \\ \mathrm{Spec}(\mathbf{Z}[x] \otimes_{\mathbf{Z}} \mathbf{Z}[x]) &\rightarrow \mathrm{Spec}(\mathbf{Z}[x]) \\ \mathbf{Z}[x] \otimes_{\mathbf{Z}} \mathbf{Z}[x] &\leftarrow \mathbf{Z}[x] \\ x \otimes 1 + 1 \otimes x &\leftarrow x \end{aligned}$$

Hence we see that \mathbf{G}_a is a group scheme over \mathbf{Z} . For any scheme S the base change $\mathbf{G}_{a,S}$ is a group scheme over S whose functor of points is

$$T/S \mapsto \mathbf{G}_{a,S}(T) = \mathbf{G}_a(T) = \Gamma(T, \mathcal{O}_T)$$

as before.

Example 38.5.4 (General linear group scheme). Let $n \geq 1$. Consider the functor which associates to any scheme T the group

$$\mathrm{GL}_n(\Gamma(T, \mathcal{O}_T))$$

of invertible $n \times n$ matrices over the global sections of the structure sheaf. This is representable by the scheme

$$\mathrm{GL}_n = \mathrm{Spec}(\mathbf{Z}[\{x_{ij}\}_{1 \leq i, j \leq n}][1/d])$$

where $d = \det((x_{ij}))$ with (x_{ij}) the $n \times n$ matrix with entry x_{ij} in the (i, j) -spot. The morphism giving the group structure is the morphism

$$\begin{aligned} \mathrm{GL}_n \times \mathrm{GL}_n &\rightarrow \mathrm{GL}_n \\ \mathrm{Spec}(\mathbf{Z}[x_{ij}, 1/d] \otimes_{\mathbf{Z}} \mathbf{Z}[x_{ij}, 1/d]) &\rightarrow \mathrm{Spec}(\mathbf{Z}[x_{ij}, 1/d]) \\ \mathbf{Z}[x_{ij}, 1/d] \otimes_{\mathbf{Z}} \mathbf{Z}[x_{ij}, 1/d] &\leftarrow \mathbf{Z}[x_{ij}, 1/d] \\ \sum x_{ik} \otimes x_{kj} &\leftarrow x_{ij} \end{aligned}$$

Hence we see that GL_n is a group scheme over \mathbf{Z} . For any scheme S the base change $\mathrm{GL}_{n,S}$ is a group scheme over S whose functor of points is

$$T/S \mapsto \mathrm{GL}_{n,S}(T) = \mathrm{GL}_n(T) = \mathrm{GL}_n(\Gamma(T, \mathcal{O}_T))$$

as before.

Example 38.5.5. The determinant defines a morphisms of group schemes

$$\det : \mathrm{GL}_n \longrightarrow \mathbf{G}_m$$

over \mathbf{Z} . By base change it gives a morphism of group schemes $\mathrm{GL}_{n,S} \rightarrow \mathbf{G}_{m,S}$ over any base scheme S .

Example 38.5.6 (Constant group). Let G be an abstract group. Consider the functor which associates to any scheme T the group of locally constant maps $T \rightarrow G$ (where T has the Zariski topology and G the discrete topology). This is representable by the scheme

$$G_{\mathrm{Spec}(\mathbf{Z})} = \coprod_{g \in G} \mathrm{Spec}(\mathbf{Z}).$$

The morphism giving the group structure is the morphism

$$G_{\mathrm{Spec}(\mathbf{Z})} \times_{\mathrm{Spec}(\mathbf{Z})} G_{\mathrm{Spec}(\mathbf{Z})} \longrightarrow G_{\mathrm{Spec}(\mathbf{Z})}$$

which maps the component corresponding to the pair (g, g') to the component corresponding to gg' . For any scheme S the base change G_S is a group scheme over S whose functor of points is

$$T/S \mapsto G_S(T) = \{f : T \rightarrow G \text{ locally constant}\}$$

as before.

38.6. Properties of group schemes

In this section we collect some simple properties of group schemes which hold over any base.

Lemma 38.6.1. *Let S be a scheme. Let G be a group scheme over S . Then $G \rightarrow S$ is separated (resp. quasi-separated) if and only if the identity morphism $e : S \rightarrow G$ is a closed immersion (resp. quasi-compact).*

Proof. We recall that by Schemes, Lemma 25.21.12 we have that e is an immersion which is a closed immersion (resp. quasi-compact) if $G \rightarrow S$ is separated (resp. quasi-separated). For the converse, consider the diagram

$$\begin{array}{ccc} G & \xrightarrow{\Delta_{G/S}} & G \times_S G \\ \downarrow & & \downarrow (g, g') \mapsto m(i(g), g') \\ S & \xrightarrow{e} & G \end{array}$$

It is an exercise in the functorial point of view in algebraic geometry to show that this diagram is cartesian. In other words, we see that $\Delta_{G/S}$ is a base change of e . Hence if e is a closed immersion (resp. quasi-compact) so is $\Delta_{G/S}$, see Schemes, Lemma 25.18.2 (resp. Schemes, Lemma 25.19.3). \square

Lemma 38.6.2. *Let S be a scheme. Let G be a group scheme over S . Let T be a scheme over S and let $\psi : T \rightarrow G$ be a morphism over S . If T is flat over S , then the morphism*

$$T \times_S G \rightarrow G, \quad (t, g) \mapsto m(\psi(t), g)$$

is flat. In particular, if G is flat over S , then $m : G \times_S G \rightarrow G$ is flat.

Proof. Consider the diagram

$$\begin{array}{ccccc} T \times_S G & \xrightarrow{(t, g) \mapsto (t, m(\psi(t), g))} & T \times_S G & \xrightarrow{\text{pr}} & G \\ & & \downarrow & & \downarrow \\ & & T & \xrightarrow{} & S \end{array}$$

The left top horizontal arrow is an isomorphism and the square is cartesian. Hence the lemma follows from Morphisms, Lemma 28.26.7. \square

Lemma 38.6.3. *Let (G, m, e, i) be a group scheme over the scheme S . Denote $f : G \rightarrow S$ the structure morphism. Assume f is flat. Then there exist canonical isomorphisms*

$$\Omega_{G/S} \cong f^* \mathcal{C}_{S/G} \cong f^* e^* \Omega_{G/S}$$

where $\mathcal{C}_{S/G}$ denotes the conormal sheaf of the immersion e . In particular, if S is the spectrum of a field, then $\Omega_{G/S}$ is a free \mathcal{O}_G -module.

Proof. In Morphisms, Lemma 28.34.5 we identified $\Omega_{G/S}$ with the conormal sheaf of the diagonal morphism $\Delta_{G/S}$. In the proof of Lemma 38.6.1 we showed that $\Delta_{G/S}$ is a base change of the immersion e by the morphism $(g, g') \mapsto m(i(g), g')$. This morphism is isomorphic to the morphism $(g, g') \mapsto m(g, g')$ hence is flat by Lemma 38.6.2. Hence we get the first isomorphism by Morphisms, Lemma 28.33.4. By Morphisms, Lemma 28.34.16 we have $\mathcal{C}_{S/G} \cong e^*\Omega_{G/S}$.

If S is the spectrum of a field, then $G \rightarrow S$ is flat, and any \mathcal{O}_S -module on S is free. \square

38.7. Properties of group schemes over a field

In this section we collect some simple properties of group schemes over a field.

Lemma 38.7.1. *If (G, m) is a group scheme over a field k , then the multiplication map $m : G \times_k G \rightarrow G$ is open.*

Proof. The multiplication map is isomorphic to the projection map $\text{pr}_0 : G \times_k G \rightarrow G$ because the diagram

$$\begin{array}{ccc} G \times_k G & \xrightarrow{(g, g') \mapsto (m(g, g'), g')} & G \times_k G \\ \downarrow m & & \downarrow (g, g') \mapsto g \\ G & \xrightarrow{\text{id}} & G \end{array}$$

is commutative with isomorphisms as horizontal arrows. The projection is open by Morphisms, Lemma 28.24.4. \square

Lemma 38.7.2. *Let G be a group scheme over a field. Then G is a separated scheme.*

Proof. Say $S = \text{Spec}(k)$ with k a field, and let G be a group scheme over S . By Lemma 38.6.1 we have to show that $e : S \rightarrow G$ is a closed immersion. By Morphisms, Lemma 28.21.2 the image of $e : S \rightarrow G$ is a closed point of G . It is clear that $\mathcal{O}_G \rightarrow e_*\mathcal{O}_S$ is surjective, since $e_*\mathcal{O}_S$ is a skyscraper sheaf supported at the neutral element of G with value k . We conclude that e is a closed immersion by Schemes, Lemma 25.24.2. \square

Lemma 38.7.3. *Let G be a group scheme over a field k . Then*

- (1) *every local ring $\mathcal{O}_{G, g}$ of G has a unique minimal prime ideal,*
- (2) *there is exactly one irreducible component Z of G passing through e , and*
- (3) *Z is geometrically irreducible over k .*

Proof. For any point $g \in G$ there exists a field extension $k \subset K$ and a K -valued point $g' \in G(K)$ mapping to g . If we think of g' as a K -rational point of the group scheme G_K , then we see that $\mathcal{O}_{G, g} \rightarrow \mathcal{O}_{G_K, g'}$ is a faithfully flat local ring map (as $G_K \rightarrow G$ is flat, and a local flat ring map is faithfully flat, see Algebra, Lemma 10.38.16). The result for $\mathcal{O}_{G_K, g'}$ implies the result for $\mathcal{O}_{G, g}$, see Algebra, Lemma 10.29.5. Hence in order to prove (1) it suffices to prove it for k -rational points g of G . In this case translation by g defines an automorphism $G \rightarrow G$ which maps e to g . Hence $\mathcal{O}_{G, g} \cong \mathcal{O}_{G, e}$. In this way we see that (2) implies (1), since irreducible components passing through e correspond one to one with minimal prime ideals of $\mathcal{O}_{G, e}$.

In order to prove (2) and (3) it suffices to prove (2) when k is algebraically closed. In this case, let Z_1, Z_2 be two irreducible components of G passing through e . Since k is algebraically closed the closed subscheme $Z_1 \times_k Z_2 \subset G \times_k G$ is irreducible too, see Varieties, Lemma 32.6.4. Hence $m(Z_1 \times_k Z_2)$ is contained in an irreducible component of G . On the other hand it contains Z_1 and Z_2 since $m|_{e \times G} = \text{id}_G$ and $m|_{G \times e} = \text{id}_G$. We conclude $Z_1 = Z_2$ as desired. \square

Remark 38.7.4. Warning: The result of Lemma 38.7.3 does not mean that every irreducible component of G/k is geometrically irreducible. For example the group scheme $\mu_{3, \mathbf{Q}} = \text{Spec}(\mathbf{Q}[x]/(x^3 - 1))$ over \mathbf{Q} has two irreducible components corresponding to the factorization $x^3 - 1 = (x - 1)(x^2 + x + 1)$. The first factor corresponds to the irreducible component passing through the identity, and the second irreducible component is not geometrically irreducible over $\text{Spec}(\mathbf{Q})$.

Lemma 38.7.5. *Let G be a group scheme which is locally of finite type over a field k . Then G is equidimensional and $\dim(G) = \dim_g(G)$ for all $g \in G$. For any closed point $g \in G$ we have $\dim(G) = \dim(\mathcal{O}_{G, g})$.*

Proof. Let us first prove that $\dim_g(G) = \dim_{g'}(G)$ for any pair of points $g, g' \in G$. By Morphisms, Lemma 28.29.3 we may extend the ground field at will. Hence we may assume that both g and g' are defined over k . Hence there exists an automorphism of G mapping g to g' , whence the equality. By Morphisms, Lemma 28.29.1 we have $\dim_g(G) = \dim(\mathcal{O}_{G, g}) + \text{trdeg}_k(\kappa(g))$. On the other hand, the dimension of G (or any open subset of G) is the supremum of the dimensions of the local rings of G , see Properties, Lemma 27.11.4. Clearly this is maximal for closed points g in which case $\text{trdeg}_k(\kappa(g)) = 0$ (by the Hilbert Nullstellensatz, see Morphisms, Section 28.17). Hence the lemma follows. \square

The following result is sometimes referred to as Cartier's theorem.

Lemma 38.7.6. *Let G be a group scheme which is locally of finite type over a field k of characteristic zero. Then the structure morphism $G \rightarrow \text{Spec}(k)$ is smooth, i.e., G is a smooth group scheme.*

Proof. By Lemma 38.6.3 the module of differentials of G over k is free. Hence smoothness follows from Varieties, Lemma 32.15.1. \square

Remark 38.7.7. Any group scheme over a field of characteristic 0 is reduced, see [Per75, I, Theorem 1.1 and I, Corollary 3.9, and II, Theorem 2.4] and also [Per76, Proposition 4.2.8]. This was a question raised in [Oor66, page 80]. We have seen in Lemma 38.7.6 that this holds when the group scheme is locally of finite type.

Lemma 38.7.8. *Let G be a group scheme which is locally of finite type over a perfect field k of characteristic $p > 0$ (see Lemma 38.7.6 for the characteristic zero case). If G is reduced then the structure morphism $G \rightarrow \text{Spec}(k)$ is smooth, i.e., G is a smooth group scheme.*

Proof. By Lemma 38.6.3 the sheaf $\Omega_{G/k}$ is free. Hence the lemma follows from Varieties, Lemma 32.15.2. \square

Remark 38.7.9. Let k be a field of characteristic $p > 0$. Let $\alpha \in k$ be an element which is not a p th power. The closed subgroup scheme

$$G = V(x^p + \alpha y^p) \subset \mathbf{G}_{a, k}^2$$

is reduced and irreducible but not smooth (not even normal).

Lemma 38.7.10. *Let G be a group scheme over a perfect field k . Then the reduction G_{red} of G is a closed subgroup scheme of G .*

Proof. Omitted. Hint: Use that $G_{red} \times_k G_{red}$ is reduced by Varieties, Lemmas 32.4.3 and 32.4.7. \square

The next lemma will be generalized slightly in More on Groupoids, Lemma 39.10.2. Namely, if $G' \rightarrow G$ is a morphism of group schemes over a field whose image is open, then its image is closed.

Lemma 38.7.11. *Let G be group scheme over a field k . Let $G' \subset G$ be an open subgroup scheme. Then G' is open and closed in G .*

Proof. Suppose that $k \subset K$ is a field extension such that $G'_K \subset G_K$ is closed. Then it follows from Morphisms, Lemma 28.26.10 that G' is closed (as $G_K \rightarrow G$ is flat, quasi-compact and surjective). Hence it suffices to prove the lemma after replacing k by some extension. Choose K to be an algebraically closed field extension of very large cardinality. Then by Varieties, Lemma 32.12.2, we see that G_K is a Jacobson scheme all of whose closed points have residue field equal to K . In other words we may assume G is a Jacobson scheme all of whose closed points have residue field k .

Let $Z = G \setminus G'$. We have to show that Z is open. Because G is Jacobson and Z is closed the closed points of Z are dense in Z . Moreover any closed point $z \in Z$ is a k -rational point and hence we translation by z defines an automorphism $L_z : G \rightarrow G$, $g \mapsto m(z, g)$ with $e \mapsto z$. As G' is a subgroup scheme we conclude that $L_z(G') \subset Z$. Altogether we see that

$$Z = \bigcup_{z \in Z(k)} L_z(G')$$

is a union of open subsets, and hence open as desired. \square

Lemma 38.7.12. *Let $i : G' \rightarrow G$ be an immersion of group schemes over a field k . Then i is a closed immersion, i.e., $i(G')$ is a closed subgroup scheme of G .*

Proof. To show that i is a closed immersion it suffices to show that $i(G')$ is a closed subset of G . Let $k \subset k'$ be a perfect extension of k . If $i(G'_{k'}) \subset G_{k'}$ is closed, then $i(G') \subset G$ is closed by Morphisms, Lemma 28.26.10 (as $G_{k'} \rightarrow G$ is flat, quasi-compact and surjective). Hence we may and do assume k is perfect. We will use without further mention that products of reduced schemes over k are reduced. We may replace G' and G by their reductions, see Lemma 38.7.10. Let $\overline{G'} \subset G$ be the closure of $i(G')$ viewed as a reduced closed subscheme. By Varieties, Lemma 32.14.1 we conclude that $\overline{G'} \times_k \overline{G'}$ is the closure of the image of $G' \times_k G' \rightarrow G \times_k G$. Hence

$$m(\overline{G'} \times_k \overline{G'}) \subset \overline{G'}$$

as m is continuous. It follows that $\overline{G'} \subset G$ is a (reduced) closed subgroup scheme. By Lemma 38.7.11 we see that $i(G') \subset \overline{G'}$ is also closed which implies that $i(G') = \overline{G'}$ as desired. \square

Lemma 38.7.13. *Let G be a group scheme over a field. There exists an open and closed subscheme $G' \subset G$ which is a countable union of affines.*

Proof. Let $e \in U(k)$ be a quasi-compact open neighbourhood of the identity element. By replacing U by $U \cap i(U)$ we may assume that U is invariant under the inverse map. As G is separated this is still a quasi-compact set. Set

$$G' = \bigcup_{n \geq 1} m_n(U \times_k \dots \times_k U)$$

where $m_n : G \times_k \dots \times_k G \rightarrow G$ is the n -slot multiplication map $(g_1, \dots, g_n) \mapsto m(m(\dots(m(g_1, g_2), g_3), \dots), g_n)$. Each of these maps are open (see Lemma 38.7.1) hence G' is an open subgroup scheme. By Lemma 38.7.11 it is also a closed subgroup scheme. \square

Remark 38.7.14. If G is a group scheme over a field, is there always a quasi-compact open and closed subgroup scheme? Or is there a counter example?

38.8. Actions of group schemes

Let (G, m) be a group and let V be a set. Recall that a (left) action of G on V is given by a map $a : G \times V \rightarrow V$ such that

- (1) (associativity) $a(m(g, g'), v) = a(g, a(g', v))$ for all $g, g' \in G$ and $v \in V$, and
- (2) (identity) $a(e, v) = v$ for all $v \in V$.

We also say that V is a G -set (this usually means we drop the a from the notation – which is abuse of notation). A map of G -sets $\psi : V \rightarrow V'$ is any set map such that $\psi(a(g, v)) = a(g, \psi(v))$ for all $v \in V$.

Definition 38.8.1. Let S be a scheme. Let (G, m) be a group scheme over S .

- (1) An action of G on the scheme X/S is a morphism $a : G \times_S X \rightarrow X$ over S such that for every T/S the map $a : G(T) \times X(T) \rightarrow X(T)$ defines the structure of a $G(T)$ -set on $X(T)$.
- (2) Suppose that X, Y are schemes over S each endowed with an action of G . An equivariant or more precisely a G -equivariant morphism $\psi : X \rightarrow Y$ is a morphism of schemes over S such that for every T/S the map $\psi : X(T) \rightarrow Y(T)$ is a morphism of $G(T)$ -sets.

In situation (1) this means that the diagrams

$$(38.8.1.1) \quad \begin{array}{ccc} G \times_S G \times_S X & \xrightarrow{1_G \times a} & G \times_S X \\ m \times 1_X \downarrow & & \downarrow a \\ G \times_S X & \xrightarrow{a} & X \end{array} \quad \begin{array}{ccc} G \times_S X & \xrightarrow{a} & X \\ \epsilon \times 1_X \uparrow & \nearrow 1_X & \\ X & & \end{array}$$

are commutative. In situation (2) this just means that the diagram

$$\begin{array}{ccc} G \times_S X & \xrightarrow{\text{id} \times f} & G \times_S Y \\ a \downarrow & & \downarrow a \\ X & \xrightarrow{f} & Y \end{array}$$

commutes.

Definition 38.8.2. Let $S, G \rightarrow S$, and $X \rightarrow S$ as in Definition 38.8.1. Let $a : G \times_S X \rightarrow X$ be an action of G on X/S . We say the action is free if for every scheme T over S the action $a : G(T) \times X(T) \rightarrow X(T)$ is a free action of the group $G(T)$ on the set $X(T)$.

Lemma 38.8.3. *Situation as in Definition 38.8.2, The action a is free if and only if*

$$G \times_S X \rightarrow X \times_S X, \quad (g, x) \mapsto (a(g, x), x)$$

is a monomorphism.

Proof. Immediate from the definitions. \square

38.9. Principal homogeneous spaces

In Cohomology on Sites, Definition 21.5.1 we have defined a torsor for a sheaf of groups on a site. Suppose $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$ is a topology and (G, m) is a group scheme over S . Since τ is stronger than the canonical topology (see Descent, Lemma 34.9.3) we see that \underline{G} (see Sites, Definition 7.13.3) is a sheaf of groups on $(\text{Sch}/S)_\tau$. Hence we already know what it means to have a torsor for \underline{G} on $(\text{Sch}/S)_\tau$. A special situation arises if this sheaf is representable. In the following definitions we define directly what it means for the representing scheme to be a G -torsor.

Definition 38.9.1. Let S be a scheme. Let (G, m) be a group scheme over S . Let X be a scheme over S , and let $a : G \times_S X \rightarrow X \times_S X$ be an action of G on X .

- (1) We say X is a *pseudo G -torsor* or that X is *formally principally homogeneous under G* if the induced morphism of schemes $G \times_S X \rightarrow X \times_S X$, $(g, x) \mapsto (a(g, x), x)$ is an isomorphism of schemes over S .
- (2) A pseudo G -torsor X is called *trivial* if there exists an G -equivariant isomorphism $G \rightarrow X$ over S where G acts on G by left multiplication.

It is clear that if $S' \rightarrow S$ is a morphism of schemes then the pullback $X_{S'}$ of a pseudo G -torsor over S is a pseudo $G_{S'}$ -torsor over S' .

Lemma 38.9.2. *In the situation of Definition 38.9.1.*

- (1) *The scheme X is a pseudo G -torsor if and only if for every scheme T over S the set $X(T)$ is either empty or the action of the group $G(T)$ on $X(T)$ is simply transitive.*
- (2) *A pseudo G -torsor X is trivial if and only if the morphism $X \rightarrow S$ has a section.*

Proof. Omitted. \square

Definition 38.9.3. Let S be a scheme. Let (G, m) be a group scheme over S . Let X be a pseudo G -torsor over S .

- (1) We say X is a *principal homogeneous space* or a *G -torsor* if there exists a fpqc covering¹ $\{S_i \rightarrow S\}_{i \in I}$ such that each $X_{S_i} \rightarrow S_i$ has a section (i.e., is a trivial pseudo G_{S_i} -torsor).
- (2) Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$. We say X is a *G -torsor in the τ topology*, or a *τ G -torsor*, or simply a *τ torsor* if there exists a τ covering $\{S_i \rightarrow S\}_{i \in I}$ such that each $X_{S_i} \rightarrow S_i$ has a section.
- (3) If X is a G -torsor, then we say that it is *quasi-isotrivial* if it is a torsor for the étale topology.

¹This means that the default type of torsor is a pseudo torsor which is trivial on an fpqc covering. This is the definition in [ABD⁺66, Exposé IV, 6.5]. It is a little bit inconvenient for us as we most often work in the fppf topology.

- (4) If X is a G -torsor, then we say that it is *locally trivial* if it is a torsor for the Zariski topology.

We sometimes say “let X be a G -torsor over S ” to indicate that X is a scheme over S equipped with an action of G which turns it into a principal homogeneous space over S . Next we show that this agrees with the notation introduced earlier when both apply.

Lemma 38.9.4. *Let S be a scheme. Let (G, m) be a group scheme over S . Let X be a scheme over S , and let $a : G \times_S X \rightarrow X$ be an action of G on X . Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$. Then X is a G -torsor in the τ -topology if and only if \underline{X} is a \underline{G} -torsor on $(\text{Sch}/S)_\tau$.*

Proof. Omitted. □

Remark 38.9.5. Let (G, m) be a group scheme over the scheme S . In this situation we have the following natural types of questions:

- (1) If $X \rightarrow S$ is a pseudo G -torsor and $X \rightarrow S$ is surjective, then is X necessarily a G -torsor?
- (2) Is every \underline{G} -torsor on $(\text{Sch}/S)_{\text{fppf}}$ representable? In other words, does every \underline{G} -torsor come from a fppf G -torsor?
- (3) Is every G -torsor an fppf (resp. smooth, resp. étale, resp. Zariski) torsor?

In general the answers to these questions is no. To get a positive answer we need to impose additional conditions on $G \rightarrow S$. For example: If S is the spectrum of a field, then the answer to (1) is yes because then $\{X \rightarrow S\}$ is a fpqc covering trivializing X . If $G \rightarrow S$ is affine, then the answer to (2) is yes (insert future reference here). If $G = \text{GL}_{n,S}$ then the answer to (3) is yes and in fact any $\text{GL}_{n,S}$ -torsor is locally trivial (insert future reference here).

38.10. Equivariant quasi-coherent sheaves

We think of “functions” as dual to “space”. Thus for a morphism of spaces the map on functions goes the other way. Moreover, we think of the sections of a sheaf of modules as “functions”. This leads us naturally to the direction of the arrows chosen in the following definition.

Definition 38.10.1. Let S be a scheme, let (G, m) be a group scheme over S , and let $a : G \times_S X \rightarrow X$ be an action of the group scheme G on X/S . An G -equivariant quasi-coherent \mathcal{O}_X -module, or simply a *equivariant quasi-coherent \mathcal{O}_X -module*, is a pair (\mathcal{F}, α) , where \mathcal{F} is a quasi-coherent \mathcal{O}_X -module, and α is a $\mathcal{O}_{G \times_S X}$ -module map

$$\alpha : a^* \mathcal{F} \longrightarrow \text{pr}_1^* \mathcal{F}$$

where $\text{pr}_1 : G \times_S X \rightarrow X$ is the projection such that

- (1) the diagram

$$\begin{array}{ccc} (1_G \times a)^* \text{pr}_2^* \mathcal{F} & \xrightarrow{\text{pr}_{12}^* \alpha} & \text{pr}_2^* \mathcal{F} \\ (1_G \times a)^* \alpha \uparrow & & \uparrow (m \times 1_X)^* \alpha \\ (1_G \times a)^* a^* \mathcal{F} & \xlongequal{\quad} & (m \times 1_X)^* a^* \mathcal{F} \end{array}$$

is commutative in the category of $\mathcal{O}_{G \times_S G \times_S X}$ -modules, and

(2) the pullback

$$(e \times 1_X)^* \alpha : \mathcal{F} \longrightarrow \mathcal{F}$$

is the identity map.

For explanation compare with the relevant diagrams of Equation (38.8.1.1).

Note that the commutativity of the first diagram guarantees that $(e \times 1_X)^* \alpha$ is an idempotent operator on \mathcal{F} , and hence condition (2) is just the condition that it is an isomorphism.

Lemma 38.10.2. *Let S be a scheme. Let G be a group scheme over S . Let $f : X \rightarrow Y$ be a G -equivariant morphism between S -schemes endowed with G -actions. Then pullback f^* given by $(\mathcal{F}, \alpha) \mapsto (f^* \mathcal{F}, (1_G \times f)^* \alpha)$ defines a functor from the category of G -equivariant sheaves on X to the category of quasi-coherent G -equivariant sheaves on Y .*

Proof. Omitted. □

38.11. Groupoids

Recall that a groupoid is a category in which every morphism is an isomorphism, see Categories, Definition 4.2.5. Hence a groupoid has a set of objects Ob , a set of arrows Arrows , a *source* and *target* map $s, t : \text{Arrows} \rightarrow \text{Ob}$, and a *composition law* $c : \text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows} \rightarrow \text{Arrows}$. These maps satisfy exactly the following axioms

- (1) (associativity) $c \circ (1, c) = c \circ (c, 1)$ as maps $\text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows} \rightarrow \text{Arrows}$,
- (2) (identity) there exists a map $e : \text{Ob} \rightarrow \text{Arrows}$ such that
 - (a) $s \circ e = t \circ e = \text{id}$ as maps $\text{Ob} \rightarrow \text{Ob}$,
 - (b) $c \circ (1, e \circ s) = c \circ (e \circ t, 1) = 1$ as maps $\text{Arrows} \rightarrow \text{Arrows}$,
- (3) (inverse) there exists a map $i : \text{Arrows} \rightarrow \text{Arrows}$ such that
 - (a) $s \circ i = t, t \circ i = s$ as maps $\text{Arrows} \rightarrow \text{Ob}$, and
 - (b) $c \circ (1, i) = e \circ t$ and $c \circ (i, 1) = e \circ s$ as maps $\text{Arrows} \rightarrow \text{Arrows}$.

If this is the case the maps e and i are uniquely determined and i is a bijection. Note that if $(\text{Ob}', \text{Arrows}', s', t', c')$ is a second groupoid category, then a functor $f : (\text{Ob}, \text{Arrows}, s, t, c) \rightarrow (\text{Ob}', \text{Arrows}', s', t', c')$ is given by a pair of set maps $f : \text{Ob} \rightarrow \text{Ob}'$ and $f : \text{Arrows} \rightarrow \text{Arrows}'$ such that $s' \circ f = f \circ s, t' \circ f = f \circ t$, and $c' \circ (f, f) = f \circ c$. The compatibility with identity and inverse is automatic. We will use this below. (Warning: The compatibility with identity has to be imposed in the case of general categories.)

Definition 38.11.1. Let S be a scheme.

- (1) A *groupoid scheme over S* , or simply a *groupoid over S* is a quintuple (U, R, s, t, c) where U and R are schemes over S , and $s, t : R \rightarrow U$ and $c : R \times_{s, U, t} R \rightarrow R$ are morphisms of schemes over S with the following property: For any scheme T over S the quintuple

$$(U(T), R(T), s, t, c)$$

is a groupoid category in the sense described above.

- (2) A morphism $f : (U, R, s, t, c) \rightarrow (U', R', s', t', c')$ of groupoid schemes over S is given by morphisms of schemes $f : U \rightarrow U'$ and $f : R \rightarrow R'$ with the following property: For any scheme T over S the maps f define a functor from the groupoid category $(U(T), R(T), s, t, c)$ to the groupoid category $(U'(T), R'(T), s', t', c')$.

Let (U, R, s, t, c) be a groupoid over S . Note that, by the remarks preceding the definition and the Yoneda lemma, there are unique morphisms of schemes $e : U \rightarrow R$ and $i : R \rightarrow R$ over S such that for every scheme T over S the induced map $e : U(T) \rightarrow R(T)$ is the identity, and $i : R(T) \rightarrow R(T)$ is the inverse of the groupoid category. The septuple (U, R, s, t, c, e, i) satisfies commutative diagrams corresponding to each of the axioms (1), (2)(a), (2)(b), (3)(a) and (3)(b) above, and conversely given a septuple with this property the quintuple (U, R, s, t, c) is a groupoid scheme. Note that i is an isomorphism, and e is a section of both s and t . Moreover, given a groupoid scheme over S we denote

$$j = (t, s) : R \rightarrow U \times_S U$$

which is compatible with our conventions in Section 38.3 above. We sometimes say “let (U, R, s, t, c, e, i) be a groupoid over S ” to stress the existence of identity and inverse.

Lemma 38.11.2. *Given a groupoid scheme (U, R, s, t, c) over S the morphism $j : R \rightarrow U \times_S U$ is a pre-equivalence relation.*

Proof. Omitted. This is a nice exercise in the definitions. □

Lemma 38.11.3. *Given an equivalence relation $j : R \rightarrow U$ over S there is a unique way to extend it to a groupoid (U, R, s, t, c) over S .*

Proof. Omitted. This is a nice exercise in the definitions. □

Lemma 38.11.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . In the commutative diagram*

the two lower squares are fibre product squares. Moreover, the triangle on top (which is really a square) is also cartesian.

Proof. Omitted. Exercise in the definitions and the functorial point of view in algebraic geometry. □

Lemma 38.11.5. *Let S be a scheme. Let (U, R, s, t, c, e, i) be a groupoid over S . The diagram*

$$(38.11.5.1) \quad \begin{array}{ccccc} R \times_{t,U,t} R & \xrightarrow{pr_1} & R & \xrightarrow{t} & U \\ \downarrow pr_0 \times c \circ (i,1) & \searrow pr_0 & \downarrow id_R & & \downarrow id_U \\ R \times_{s,U,t} R & \xrightarrow{c} & R & \xrightarrow{t} & U \\ \downarrow pr_1 & & \downarrow s & & \\ R & \xrightarrow{s} & U & \xrightarrow{t} & \end{array}$$

is commutative. The two top rows are isomorphic via the vertical maps given. The two lower left squares are cartesian.

Proof. The commutativity of the diagram follows from the axioms of a groupoid. Note that, in terms of groupoids, the top left vertical arrow assigns to a pair of morphisms (α, β) with the same target, the pair of morphisms $(\alpha, \alpha^{-1} \circ \beta)$. In any groupoid this defines a bijection between $\text{Arrows} \times_{t, \text{Ob}, t} \text{Arrows}$ and $\text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows}$. Hence the second assertion of the lemma. The last assertion follows from Lemma 38.11.4. \square

38.12. Quasi-coherent sheaves on groupoids

See the introduction of Section 38.10 for our choices in direction of arrows.

Definition 38.12.1. Let S be a scheme, let (U, R, s, t, c) be a groupoid scheme over S . A quasi-coherent module on (U, R, s, t, c) is a pair (\mathcal{F}, α) , where \mathcal{F} is a quasi-coherent \mathcal{O}_U -module, and α is a \mathcal{O}_R -module map

$$\alpha : t^* \mathcal{F} \longrightarrow s^* \mathcal{F}$$

such that

- (1) the diagram

$$\begin{array}{ccc} pr_1^* t^* \mathcal{F} & \xrightarrow{pr_1^* \alpha} & pr_1^* s^* \mathcal{F} \\ \parallel & & \parallel \\ pr_0^* s^* \mathcal{F} & & c^* s^* \mathcal{F} \\ \swarrow pr_0^* \alpha & & \swarrow c^* \alpha \\ pr_0^* t^* \mathcal{F} & \xlongequal{\quad} & c^* t^* \mathcal{F} \end{array}$$

- is a commutative in the category of $\mathcal{O}_{R \times_{s,U,t} R}$ -modules, and
- (2) the pullback

$$e^* \alpha : \mathcal{F} \longrightarrow \mathcal{F}$$

is the identity map.

Compare with the commutative diagrams of Lemma 38.11.4.

The commutativity of the first diagram forces the operator $e^* \alpha$ to be idempotent. Hence the second condition can be reformulated as saying that $e^* \alpha$ is an isomorphism. In fact, the condition implies that α is an isomorphism.

Lemma 38.12.2. *Let S be a scheme, let (U, R, s, t, c) be a groupoid scheme over S . If (\mathcal{F}, α) is a quasi-coherent module on (U, R, s, t, c) then α is an isomorphism.*

Proof. Pull back the commutative diagram of Definition 38.12.1 by the morphism $(i, 1) : R \rightarrow R \times_{s, U, t} R$. Then we see that $i^*\alpha \circ \alpha = s^*e^*\alpha$. Pulling back by the morphism $(1, i)$ we obtain the relation $\alpha \circ i^*\alpha = t^*e^*\alpha$. By the second assumption these morphisms are the identity. Hence $i^*\alpha$ is an inverse of α . \square

Lemma 38.12.3. *Let S be a scheme. Consider a morphism $f : (U, R, s, t, c) \rightarrow (U', R', s', t', c')$ of groupoid schemes over S . Then pullback f^* given by*

$$(\mathcal{F}, \alpha) \mapsto (f^*\mathcal{F}, f^*\alpha)$$

defines a functor from the category of quasi-coherent sheaves on (U', R', s', t', c') to the category of quasi-coherent sheaves on (U, R, s, t, c) .

Proof. Omitted. \square

Lemma 38.12.4. *Let S be a scheme. Consider a morphism $f : (U, R, s, t, c) \rightarrow (U', R', s', t', c')$ of groupoid schemes over S . Assume that*

- (1) $f : U \rightarrow U'$ is quasi-compact and quasi-separated,
- (2) the square

$$\begin{array}{ccc} R & \longrightarrow & R' \\ t \downarrow & & \downarrow t' \\ U & \xrightarrow{f} & U' \end{array}$$

is cartesian, and

- (3) s' and t' are flat.

Then pushforward f_ given by*

$$(\mathcal{F}, \alpha) \mapsto (f_*\mathcal{F}, f_*\alpha)$$

defines a functor from the category of quasi-coherent sheaves on (U, R, s, t, c) to the category of quasi-coherent sheaves on (U', R', s', t', c') which is right adjoint to pullback as defined in Lemma 38.12.3.

Proof. Since $U \rightarrow U'$ is quasi-compact and quasi-separated we see that f_* transforms quasi-coherent sheaves into quasi-coherent sheaves (Schemes, Lemma 25.24.1). Moreover, since the squares

$$\begin{array}{ccc} R & \longrightarrow & R' \\ t \downarrow & & \downarrow t' \\ U & \xrightarrow{f} & U' \end{array} \quad \text{and} \quad \begin{array}{ccc} R & \longrightarrow & R' \\ s \downarrow & & \downarrow s' \\ U & \xrightarrow{f} & U' \end{array}$$

are cartesian we find that $(t')^*f_*\mathcal{F} = f_*t^*\mathcal{F}$ and $(s')^*f_*\mathcal{F} = f_*s^*\mathcal{F}$, see Cohomology of Schemes, Lemma 29.5.2. Thus it makes sense to think of $f_*\alpha$ as a map $(t')^*f_*\mathcal{F} \rightarrow (s')^*f_*\mathcal{F}$. A similar argument shows that $f_*\alpha$ satisfies the cocycle condition. The functor is adjoint to the pullback functor since pullback and pushforward on modules on ringed spaces are adjoint. Some details omitted. \square

Lemma 38.12.5. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . The category of quasi-coherent modules on (U, R, s, t, c) has colimits.*

Proof. Let $i \mapsto (\mathcal{F}_i, \alpha_i)$ be a diagram over the index category \mathcal{I} . We can form the colimit $\mathcal{F} = \operatorname{colim} \mathcal{F}_i$ which is a quasi-coherent sheaf on U , see Schemes, Section 25.24. Since colimits commute with pullback we see that $s^*\mathcal{F} = \operatorname{colim} s^*\mathcal{F}_i$ and similarly $t^*\mathcal{F} = \operatorname{colim} t^*\mathcal{F}_i$. Hence we can set $\alpha = \operatorname{colim} \alpha_i$. We omit the proof that (\mathcal{F}, α) is the colimit of the diagram in the category of quasi-coherent modules on (U, R, s, t, c) . \square

Lemma 38.12.6. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . If s, t are flat, then the category of quasi-coherent modules on (U, R, s, t, c) is abelian.*

Proof. Let $\varphi : (\mathcal{F}, \alpha) \rightarrow (\mathcal{G}, \beta)$ be a homomorphism of quasi-coherent modules on (U, R, s, t, c) . Since s is flat we see that

$$0 \rightarrow s^*\operatorname{Ker}(\varphi) \rightarrow s^*\mathcal{F} \rightarrow s^*\mathcal{G} \rightarrow s^*\operatorname{Coker}(\varphi) \rightarrow 0$$

is exact and similarly for pullback by t . Hence α and β induce isomorphisms $\kappa : t^*\operatorname{Ker}(\varphi) \rightarrow s^*\operatorname{Ker}(\varphi)$ and $\lambda : t^*\operatorname{Coker}(\varphi) \rightarrow s^*\operatorname{Coker}(\varphi)$ which satisfy the cocycle condition. Then it is straightforward to verify that $(\operatorname{Ker}(\varphi), \kappa)$ and $(\operatorname{Coker}(\varphi), \lambda)$ are a kernel and cokernel in the category of quasi-coherent modules on (U, R, s, t, c) . Moreover, the condition $\operatorname{Coim}(\varphi) = \operatorname{Im}(\varphi)$ follows because it holds over U . \square

38.13. Colimits of quasi-coherent modules

In this section we prove some technical results saying that under suitable assumptions every quasi-coherent module on a groupoid is a filtered colimit of “small” quasi-coherent modules.

Lemma 38.13.1. *Let (U, R, s, t, c) be a groupoid scheme over S . Assume s, t are flat, quasi-compact, and quasi-separated. For any quasi-coherent module \mathcal{G} on U , there exists a canonical isomorphism $\alpha : t^*t_*s^*\mathcal{G} \rightarrow s^*t_*s^*\mathcal{G}$ which turns $(t_*s^*\mathcal{G}, \alpha)$ into a quasi-coherent module on (U, R, s, t, c) . This construction defines a functor*

$$QCoh(\mathcal{O}_U) \longrightarrow QCoh(U, R, s, t, c)$$

which is a right adjoint to the forgetful functor $(\mathcal{F}, \beta) \mapsto \mathcal{F}$.

Proof. The pushforward of a quasi-coherent module along a quasi-compact and quasi-separated morphism is quasi-coherent, see Schemes, Lemma 25.24.1. Hence $t_*s^*\mathcal{G}$ is quasi-coherent. With notation as in Lemma 38.11.4 we have

$$t^*t_*s^*\mathcal{G} = \operatorname{pr}_{0,*}c^*s^*\mathcal{G} = \operatorname{pr}_{0,*}\operatorname{pr}_1^*s^*\mathcal{G} = s^*t_*s^*\mathcal{G}$$

The middle equality because $s \circ c = s \circ \operatorname{pr}_1$ as morphisms $R \times_{s,U,t} R \rightarrow U$, and the first and the last equality because we know that base change and pushforward commute in these steps by Cohomology of Schemes, Lemma 29.5.2.

To verify the cocycle condition of Definition 38.12.1 for α and the adjointness property we describe the construction $\mathcal{G} \mapsto (\mathcal{G}, \alpha)$ in another way. Consider the groupoid scheme $(R, R \times_{s,U,s} R, \operatorname{pr}_0, \operatorname{pr}_1, \operatorname{pr}_{02})$ associated to the equivalence relation $R \times_{s,U,s} R$ on R , see Lemma 38.11.3. There is a morphism

$$f : (R, R \times_{s,U,s} R, \operatorname{pr}_1, \operatorname{pr}_0, \operatorname{pr}_{02}) \longrightarrow (U, R, s, t, c)$$

of groupoid schemes given by $t : R \rightarrow U$ and $R \times_{t,U,t} R \rightarrow R$ given by $(r_0, r_1) \mapsto r_0 \circ r_1^{-1}$ (we omit the verification of the commutativity of the required diagrams).

Since $t, s : R \rightarrow U$ are quasi-compact, quasi-separated, and flat, and since we have a cartesian square

$$\begin{array}{ccc} R \times_{s,U,s} R & \xrightarrow{(r_0, r_1) \mapsto r_0 \circ r_1^{-1}} & R \\ \text{pr}_0 \downarrow & & \downarrow t \\ R & \xrightarrow{t} & U \end{array}$$

by Lemma 38.11.5 it follows that Lemma 38.12.4 applies to f . Note that

$$QCoh(R, R \times_{s,U,s} R, \text{pr}_0, \text{pr}_1, \text{pr}_0) = QCoh(\mathcal{O}_U)$$

by the theory of descent of quasi-coherent sheaves as $\{t : R \rightarrow U\}$ is an fpqc covering, see Descent, Proposition 34.5.2. Observe that pullback along f agrees with the forgetful functor and that pushforward agrees with the construction that assigns to \mathcal{G} the pair (\mathcal{G}, α) . We omit the precise verifications. Thus the lemma follows from Lemma 38.12.4. \square

Lemma 38.13.2. *Let $f : Y \rightarrow X$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module, let \mathcal{G} be a quasi-coherent \mathcal{O}_Y -module, and let $\varphi : \mathcal{G} \rightarrow f^*\mathcal{F}$ be a module map. Assume*

- (1) φ is injective,
- (2) f is quasi-compact, quasi-separated, flat, and surjective,
- (3) X, Y are locally Noetherian, and
- (4) \mathcal{G} is a coherent \mathcal{O}_Y -module.

Then $\mathcal{F} \cap f_*\mathcal{G}$ defined as the pullback

$$\begin{array}{ccc} \mathcal{F} & \longrightarrow & f_*f^*\mathcal{F} \\ \uparrow & & \uparrow \\ \mathcal{F} \cap f_*\mathcal{G} & \longrightarrow & f_*\mathcal{G} \end{array}$$

is a coherent \mathcal{O}_X -module.

Proof. We will freely use the characterization of coherent modules of Cohomology of Schemes, Lemma 29.9.1 as well as the fact that coherent modules form a Serre subcategory of $QCoh(\mathcal{O}_X)$, see Cohomology of Schemes, Lemma 29.9.3. If f has a section σ , then we see that $\mathcal{F} \cap f_*\mathcal{G}$ is contained in the image of $\sigma^*\mathcal{G} \rightarrow \sigma^*f^*\mathcal{F} = \mathcal{F}$, hence coherent. In general, to show that $\mathcal{F} \cap f_*\mathcal{G}$ is coherent, it suffices to show that $f^*(\mathcal{F} \cap f_*\mathcal{G})$ is coherent (see Descent, Lemma 34.6.1). Since f is flat this is equal to $f^*\mathcal{F} \cap f^*f_*\mathcal{G}$. Since f is flat, quasi-compact, and quasi-separated we see $f^*f_*\mathcal{G} = p_*q^*\mathcal{G}$ where $p, q : Y \times_X Y \rightarrow Y$ are the projections, see Cohomology of Schemes, Lemma 29.5.2. Since p has a section we win. \square

Let S be a scheme. Let (U, R, s, t, c) be a groupoid in schemes over S . Assume that U is locally Noetherian. In the lemma below we say that a quasi-coherent sheaf (\mathcal{F}, α) on (U, R, s, t, c) is *coherent* if \mathcal{F} is a coherent \mathcal{O}_U -module.

Lemma 38.13.3. *Let (U, R, s, t, c) be a groupoid scheme over S . Assume that*

- (1) U, R are Noetherian,
- (2) s, t are flat, quasi-compact, and quasi-separated.

Then every quasi-coherent module (\mathcal{F}, α) on (U, R, s, t, c) is a filtered colimit of coherent modules.

Proof. We will use the characterization of Cohomology of Schemes, Lemma 29.9.1 of coherent modules on locally Noetherian scheme without further mention. Write $\mathcal{F} = \text{colim } \mathcal{H}_i$ with \mathcal{H}_i coherent, see Properties, Lemma 27.20.6. Given a quasi-coherent sheaf \mathcal{H} on U we denote $t_*s^*\mathcal{H}$ the quasi-coherent sheaf on (U, R, s, t, c) of Lemma 38.13.1. There is an adjunction map $\mathcal{F} \rightarrow t_*s^*\mathcal{F}$ in $QCoh(U, R, s, t, c)$. Consider the pullback diagram

$$\begin{array}{ccc} \mathcal{F} & \longrightarrow & t_*s^*\mathcal{F} \\ \uparrow & & \uparrow \\ \mathcal{F}_i & \longrightarrow & t_*s^*\mathcal{H}_i \end{array}$$

in other words $\mathcal{F}_i = \mathcal{F} \cap t_*s^*\mathcal{H}_i$. Then \mathcal{F}_i is coherent by Lemma 38.13.2. On the other hand, the diagram above is a pullback diagram in $QCoh(U, R, s, t, c)$ also as restriction to U is an exact functor by (the proof of) Lemma 38.12.6. Finally, because t is quasi-compact and quasi-separated we see that t_* commutes with colimits (see Cohomology of Schemes, Lemma 29.6.1). Hence $t_*s^*\mathcal{F} = \text{colim } t_*s^*\mathcal{H}_i$ and hence $\mathcal{F} = \text{colim } \mathcal{F}_i$ as desired. \square

Here is a curious lemma that is useful when working with groupoids on fields. In fact, this is the standard argument to prove that any representation of an algebraic group is a colimit of finite dimensional representations.

Lemma 38.13.4. *Let (U, R, s, t, c) be a groupoid scheme over S . Assume that*

- (1) U, R are affine,
- (2) there exist $e_i \in \mathcal{O}_R(R)$ such that every element $g \in \mathcal{O}_R(R)$ can be uniquely written as $\sum s^*(f_i)e_i$ for some $f_i \in \mathcal{O}_U(U)$.

Then every quasi-coherent module (\mathcal{F}, α) on (U, R, s, t, c) is a filtered colimit of finite type quasi-coherent modules.

Proof. The assumption means that $\mathcal{O}_R(R)$ is a free $\mathcal{O}_U(U)$ -module via s with basis e_i . Hence for any quasi-coherent $\mathcal{O}_U(U)$ -module \mathcal{G} we see that $s^*\mathcal{G}(R) = \bigoplus_i \mathcal{G}(U)e_i$. We will write $s(-)$ to indicate pullback of sections by s and similarly for other morphisms. Let (\mathcal{F}, α) be a quasi-coherent module on (U, R, s, t, c) . Let $\sigma \in \mathcal{F}(U)$. By the above we can write

$$\alpha(t(\sigma)) = \sum s(\sigma_i)e_i$$

for some unique $\sigma_i \in \mathcal{F}(U)$ (all but finitely many are zero of course). We can also write

$$c(e_i) = \sum \text{pr}_1(f_{ij})\text{pr}_0(e_j)$$

as functions on $R \times_{s,U,t} R$. Then the commutativity of the diagram in Definition 38.12.1 means that

$$\sum \text{pr}_1(\alpha(t(\sigma_i)))\text{pr}_0(e_i) = \sum \text{pr}_1(s(\sigma_i)f_{ij})\text{pr}_0(e_j)$$

(calculation omitted). Picking off the coefficients of $\text{pr}_0(e_l)$ we see that $\alpha(t(\sigma_l)) = \sum s(\sigma_i)f_{il}$. Hence the submodule $\mathcal{G} \subset \mathcal{F}$ generated by the elements σ_i defines a finite type quasi-coherent module preserved by α . Hence it is a subobject of \mathcal{F} in $QCoh(U, R, s, t, c)$. This submodule contains σ (as one sees by pulling back the first relation by e). Hence we win. \square

We suggest the reader skip the rest of this section. Let S be a scheme. Let (U, R, s, t, c) be a groupoid in schemes over S . Let κ be a cardinal. In the following we will say that a quasi-coherent sheaf (\mathcal{F}, α) on (U, R, s, t, c) is κ -generated if \mathcal{F} is a κ -generated \mathcal{O}_U -module, see Properties, Definition 27.21.1.

Lemma 38.13.5. *Let (U, R, s, t, c) be a groupoid scheme over S . Let κ be a cardinal. There exists a set T and a family $(\mathcal{F}_t, \alpha_t)_{t \in T}$ of κ -generated quasi-coherent modules on (U, R, s, t, c) such that every κ -generated quasi-coherent module on (U, R, s, t, c) is isomorphic to one of the $(\mathcal{F}_t, \alpha_t)$.*

Proof. For each quasi-coherent module \mathcal{F} on U there is a (possibly empty) set of maps $\alpha : t^*\mathcal{F} \rightarrow s^*\mathcal{F}$ such that (\mathcal{F}, α) is a quasi-coherent modules on (U, R, s, t, c) . By Properties, Lemma 27.21.2 there exists a set of isomorphism classes of κ -generated quasi-coherent \mathcal{O}_U -modules. \square

Lemma 38.13.6. *Let (U, R, s, t, c) be a groupoid scheme over S . Assume that s, t are flat. There exists a cardinal κ such that every quasi-coherent module (\mathcal{F}, α) on (U, R, s, t, c) is the directed colimit of its κ -generated quasi-coherent submodules.*

Proof. In the statement of the lemma and in this proof a *submodule* of a quasi-coherent module (\mathcal{F}, α) is a quasi-coherent submodule $\mathcal{G} \subset \mathcal{F}$ such that $\alpha(t^*\mathcal{G}) = s^*\mathcal{G}$ as subsheaves of $s^*\mathcal{F}$. This makes sense because since s, t are flat the pullbacks s^* and t^* are exact, i.e., preserve subsheaves. The proof will be a repeat of the proof of Properties, Lemma 27.21.3. We urge the reader to read that proof first.

Choose an affine open covering $U = \bigcup_{i \in I} U_i$. For each pair i, j choose affine open coverings

$$U_i \cap U_j = \bigcup_{k \in I_{ij}} U_{ijk} \quad \text{and} \quad s^{-1}(U_i) \cap t^{-1}(U_j) = \bigcup_{k \in J_{ij}} W_{ijk}.$$

Write $U_i = \text{Spec}(A_i)$, $U_{ijk} = \text{Spec}(A_{ijk})$, $W_{ijk} = \text{Spec}(B_{ijk})$. Let κ be any infinite cardinal \geq than the cardinality of any of the sets I, I_{ij}, J_{ij} .

Let (\mathcal{F}, α) be a quasi-coherent module on (U, R, s, t, c) . Set $M_i = \mathcal{F}(U_i)$, $M_{ijk} = \mathcal{F}(U_{ijk})$. Note that

$$M_i \otimes_{A_i} A_{ijk} = M_{ijk} = M_j \otimes_{A_j} A_{ijk}$$

and that α gives isomorphisms

$$\alpha|_{W_{ijk}} : M_i \otimes_{A_i, t} B_{ijk} \longrightarrow M_j \otimes_{A_j, s} B_{ijk}$$

see Schemes, Lemma 25.7.3. Using the axiom of choice we choose a map

$$(i, j, k, m) \mapsto S(i, j, k, m)$$

which associates to every $i, j \in I, k \in I_{ij}$ or $k \in J_{ij}$ and $m \in M_i$ a finite subset $S(i, j, k, m) \subset M_j$ such that we have

$$m \otimes 1 = \sum_{m' \in S(i, j, k, m)} m' \otimes a_{m'} \quad \text{or} \quad \alpha(m \otimes 1) = \sum_{m' \in S(i, j, k, m)} m' \otimes b_{m'}$$

in M_{ijk} for some $a_{m'} \in A_{ijk}$ or $b_{m'} \in B_{ijk}$. Moreover, let's agree that $S(i, i, k, m) = \{m\}$ for all $i, j = i, k, m$ when $k \in I_{ij}$. Fix such a collection $S(i, j, k, m)$

Given a family $\mathcal{S} = (S_i)_{i \in I}$ of subsets $S_i \subset M_i$ of cardinality at most κ we set $\mathcal{S}' = (S'_i)$ where

$$S'_j = \bigcup_{(i, j, k, m) \text{ such that } m \in S_i} S(i, j, k, m)$$

Note that $S_i \subset S'_i$. Note that S'_i has cardinality at most κ because it is a union over a set of cardinality at most κ of finite sets. Set $\mathcal{S}^{(0)} = \mathcal{S}$, $\mathcal{S}^{(1)} = \mathcal{S}'$ and by induction $\mathcal{S}^{(n+1)} = (\mathcal{S}^{(n)})'$. Then set $\mathcal{S}^{(\infty)} = \bigcup_{n \geq 0} \mathcal{S}^{(n)}$. Writing $\mathcal{S}^{(\infty)} = (S_i^{(\infty)})$ we see that for any element $m \in S_i^{(\infty)}$ the image of m in M_{ijk} can be written as a finite sum $\sum m' \otimes a_{m'}$ with $m' \in S_j^{(\infty)}$. In this way we see that setting

$$N_i = A_i\text{-submodule of } M_i \text{ generated by } S_i^{(\infty)}$$

we have

$$N_i \otimes_{A_i} A_{ijk} = N_j \otimes_{A_j} A_{ijk} \quad \text{and} \quad \alpha(N_i \otimes_{A_i, t} B_{ijk}) = N_j \otimes_{A_j, s} B_{ijk}$$

as submodules of M_{ijk} or $M_j \otimes_{A_j, s} B_{ijk}$. Thus there exists a quasi-coherent submodule $\mathcal{G} \subset \mathcal{F}$ with $\mathcal{G}(U_i) = N_i$ such that $\alpha(t^*\mathcal{G}) = s^*\mathcal{G}$ as submodules of $s^*\mathcal{F}$. In other words, $(\mathcal{G}, \alpha|_{t^*\mathcal{G}})$ is a submodule of (\mathcal{F}, α) . Moreover, by construction \mathcal{G} is κ -generated.

Let $\{(\mathcal{G}_t, \alpha_t)\}_{t \in T}$ be the set of κ -generated quasi-coherent submodules of (\mathcal{F}, α) . If $t, t' \in T$ then $\mathcal{G}_t + \mathcal{G}_{t'}$ is also a κ -generated quasi-coherent submodule as it is the image of the map $\mathcal{G}_t \oplus \mathcal{G}_{t'} \rightarrow \mathcal{F}$. Hence the system (ordered by inclusion) is directed. The arguments above show that every section of \mathcal{F} over U_i is in one of the \mathcal{G}_t (because we can start with \mathcal{S} such that the given section is an element of S_i). Hence $\text{colim}_t \mathcal{G}_t \rightarrow \mathcal{F}$ is both injective and surjective as desired. \square

38.14. Groupoids and group schemes

There are many ways to construct a groupoid out of an action a of a group G on a set V . We choose the one where we think of an element $g \in G$ as an arrow with source v and target $a(g, v)$. This leads to the following construction for group actions of schemes.

Lemma 38.14.1. *Let S be a scheme. Let Y be a scheme over S . Let (G, m) be a group scheme over Y with identity e_G and inverse i_G . Let X/Y be a scheme over Y and let $a : G \times_Y X \rightarrow X$ be an action of G on X/Y . Then we get a groupoid scheme (U, R, s, t, c, e, i) over S in the following manner:*

- (1) We set $U = X$, and $R = G \times_Y X$.
- (2) We set $s : R \rightarrow U$ equal to $(g, x) \mapsto x$.
- (3) We set $t : R \rightarrow U$ equal to $(g, x) \mapsto a(g, x)$.
- (4) We set $c : R \times_{s, U, t} R \rightarrow R$ equal to $((g, x), (g', x')) \mapsto (m(g, g'), x')$.
- (5) We set $e : U \rightarrow R$ equal to $x \mapsto (e_G(x), x)$.
- (6) We set $i : R \rightarrow R$ equal to $(g, x) \mapsto (i_G(g), a(g, x))$.

Proof. Omitted. Hint: It is enough to show that this works on the set level. For this use the description above the lemma describing g as an arrow from v to $a(g, v)$. \square

Lemma 38.14.2. *Let S be a scheme. Let Y be a scheme over S . Let (G, m) be a group scheme over Y . Let X be a scheme over Y and let $a : G \times_Y X \rightarrow X$ be an action of G on X over Y . Let (U, R, s, t, c) be the groupoid scheme constructed in Lemma 38.14.1. The rule $(\mathcal{F}, \alpha) \mapsto (\mathcal{F}, \alpha)$ defines an equivalence of categories between G -equivariant \mathcal{O}_X -modules and the category of quasi-coherent modules on (U, R, s, t, c) .*

Proof. The assertion makes sense because $t = a$ and $s = \text{pr}_1$ as morphisms $R = G \times_Y X \rightarrow X$, see Definitions 38.10.1 and 38.12.1. Using the translation in Lemma 38.14.1 the commutativity requirements of the two definitions match up exactly. \square

38.15. The stabilizer group scheme

Given a groupoid scheme we get a group scheme as follows.

Lemma 38.15.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . The scheme G defined by the cartesian square*

$$\begin{array}{ccc} G & \longrightarrow & R \\ \downarrow & & \downarrow j=(t,s) \\ U & \xrightarrow{\Delta} & U \times_S U \end{array}$$

is a group scheme over U with composition law m induced by the composition law c .

Proof. This is true because in a groupoid category the set of self maps of any object forms a group. \square

Since Δ is an immersion we see that $G = j^{-1}(\Delta_{U/S})$ is a locally closed subscheme of R . Thinking of it in this way, the structure morphism $j^{-1}(\Delta_{U/S}) \rightarrow U$ is induced by either s or t (it is the same), and m is induced by c .

Definition 38.15.2. Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . The group scheme $j^{-1}(\Delta_{U/S}) \rightarrow U$ is called the *stabilizer of the groupoid scheme* (U, R, s, t, c) .

In the literature the stabilizer group scheme is often denoted S (because the word stabilizer starts with an “s” presumably); we cannot do this since we have already used S for the base scheme.

Lemma 38.15.3. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S , and let G/U be its stabilizer. Denote R_t/U the scheme R seen as a scheme over U via the morphism $t : R \rightarrow U$. There is a canonical left action*

$$a : G \times_U R_t \longrightarrow R_t$$

induced by the composition law c .

Proof. In terms of points over T/S we define $a(g, r) = c(g, r)$. \square

Lemma 38.15.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let G be the stabilizer group scheme of R . Let*

$$G_0 = G \times_{U, \text{pr}_0} (U \times_S U) = G \times_S U$$

as a group scheme over $U \times_S U$. The action of G on R of Lemma 38.15.3 induces an action of G_0 on R over $U \times_S U$ which turns R into a pseudo G_0 -torsor over $U \times_S U$.

Proof. This is true because in a groupoid category \mathcal{C} the set $\text{Mor}_{\mathcal{C}}(x, y)$ is a principal homogeneous set under the group $\text{Mor}_{\mathcal{C}}(y, y)$. \square

Lemma 38.15.5. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $p \in U \times_S U$ be a point. Denote R_p the scheme theoretic fibre of $j = (t, s) : R \rightarrow U \times_S U$. If $R_p \neq \emptyset$, then the action*

$$G_{0, \kappa(p)} \times_{\kappa(p)} R_p \longrightarrow R_p$$

(see Lemma 38.15.4) which turns R_p into a $G_{\kappa(p)}$ -torsor over $\kappa(p)$.

Proof. The action is a pseudo-torsor by the lemma cited in the statement. And if R_p is not the empty scheme, then $\{R_p \rightarrow p\}$ is an fpqc covering which trivializes the pseudo-torsor. \square

38.16. Restricting groupoids

Consider a (usual) groupoid $\mathcal{C} = (\text{Ob}, \text{Arrows}, s, t, c)$. Suppose we have a map of sets $g : \text{Ob}' \rightarrow \text{Ob}$. Then we can construct a groupoid $\mathcal{C}' = (\text{Ob}', \text{Arrows}', s', t', c')$ by thinking of a morphism between elements x', y' of Ob' as a morphism in \mathcal{C} between $g(x'), g(y')$. In other words we set

$$\text{Arrows}' = \text{Ob}' \times_{g, \text{Ob}, t} \text{Arrows} \times_{s, \text{Ob}, g} \text{Ob}'.$$

with obvious choices for s', t' , and c' . There is a canonical functor $\mathcal{C}' \rightarrow \mathcal{C}$ which is fully faithful, but not necessarily essentially surjective. This groupoid \mathcal{C}' endowed with the functor $\mathcal{C}' \rightarrow \mathcal{C}$ is called the *restriction* of the groupoid \mathcal{C} to Ob' .

Lemma 38.16.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ be a morphism of schemes. Consider the following diagram*

$$\begin{array}{ccccc}
 & & & s' & \\
 & & & \curvearrowright & \\
 & & & R \times_{s, U} U' & \longrightarrow & U' \\
 & & & \downarrow & & \downarrow g \\
 & & & R & \xrightarrow{s} & U \\
 & & & \downarrow t & & \\
 & & & U & \xrightarrow{g} & U \\
 & & & \uparrow & & \\
 & & & U' \times_{U, t} R & \longrightarrow & R \\
 & & & \downarrow & & \downarrow \\
 & & & U' & & U \\
 & & & \uparrow & & \\
 & & & R' & \xrightarrow{s'} & U' \\
 & & & \downarrow & & \downarrow \\
 & & & U' \times_{U, t} R & \longrightarrow & R \\
 & & & \downarrow & & \downarrow \\
 & & & U' & \xrightarrow{g} & U
 \end{array}$$

where all the squares are fibre product squares. Then there is a canonical composition law $c' : R' \times_{s', U', t'} R' \rightarrow R'$ such that (U', R', s', t', c') is a groupoid scheme over S and such that $U' \rightarrow U, R' \rightarrow R$ defines a morphism $(U', R', s', t', c') \rightarrow (U, R, s, t, c)$ of groupoid schemes over S . Moreover, for any scheme T over S the functor of groupoids

$$(U'(T), R'(T), s', t', c') \rightarrow (U(T), R(T), s, t, c)$$

is the restriction (see above) of $(U(T), R(T), s, t, c)$ via the map $U'(T) \rightarrow U(T)$.

Proof. Omitted. \square

Definition 38.16.2. Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ be a morphism of schemes. The morphism of groupoids $(U', R', s', t', c') \rightarrow (U, R, s, t, c)$ constructed in Lemma 38.16.1 is called the *restriction of (U, R, s, t, c) to U'* . We sometime use the notation $R' = R|_{U'}$ in this case.

Lemma 38.16.3. *The notions of restricting groupoids and (pre-)equivalence relations defined in Definitions 38.16.2 and 38.3.3 agree via the constructions of Lemmas 38.11.2 and 38.11.3.*

Proof. What we are saying here is that R' of Lemma 38.16.1 is also equal to

$$R' = (U' \times_S U') \times_{U \times_S U} R \longrightarrow U' \times_S U'$$

In fact this might have been a clearer way to state that lemma. \square

Lemma 38.16.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ be a morphism of schemes. Let (U', R', s', t', c') be the restriction of (U, R, s, t, c) via g . Let G be the stabilizer of (U, R, s, t, c) and let G' be the stabilizer of (U', R', s', t', c') . Then G' is the base change of G by g , i.e., there is a canonical identification $G' = U' \times_{g,U} G$.*

Proof. Omitted. \square

38.17. Invariant subschemes

In this section we discuss briefly the notion of an invariant subscheme.

Definition 38.17.1. Let (U, R, s, t, c) be a groupoid scheme over the base scheme S .

- (1) A subset $W \subset U$ is *set-theoretically R -invariant* if $t(s^{-1}(W)) \subset W$.
- (2) An open $W \subset U$ is *R -invariant* if $t(s^{-1}(W)) \subset W$.
- (3) A closed subscheme $Z \subset U$ is called *R -invariant* if $t^{-1}(Z) = s^{-1}(Z)$. Here we use the scheme theoretic inverse image, see Schemes, Definition 25.17.7.
- (4) A monomorphism of schemes $T \rightarrow U$ is *R -invariant* if $T \times_{U,t} R = R \times_{s,U} T$ as schemes over R .

For subsets and open subschemes $W \subset U$ the R -invariance is also equivalent to requiring that $s^{-1}(W) = t^{-1}(W)$ as subsets of R . If $W \subset U$ is an R -equivariant open subscheme then the restriction of R to W is just $R_W = s^{-1}(W) = t^{-1}(W)$. Similarly, if $Z \subset U$ is an R -invariant closed subscheme, then the restriction of R to Z is just $R_Z = s^{-1}(Z) = t^{-1}(Z)$.

Lemma 38.17.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S .*

- (1) *For any subset $W \subset U$ the subset $t(s^{-1}(W))$ is set-theoretically R -invariant.*
- (2) *If s and t are open, then for every open $W \subset U$ the open $t(s^{-1}(W))$ is an R -invariant open subscheme.*
- (3) *If s and t are open and quasi-compact, then U has an open covering consisting of R -invariant quasi-compact open subschemes.*

Proof. Part (1) follows from Lemmas 38.3.4 and 38.11.2, namely, $t(s^{-1}(W))$ is the set of points of U equivalent to a point of W . Next, assume s and t open and $W \subset U$ open. Since s is open the set $W' = t(s^{-1}(W))$ is an open subset of U . Finally, assume that s, t are both open and quasi-compact. Then, if $W \subset U$ is a quasi-compact open, then also $W' = t(s^{-1}(W))$ is a quasi-compact open, and invariant by the discussion above. Letting W range over all affine opens of U we see (3). \square

Lemma 38.17.3. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume s and t quasi-compact and flat and U quasi-separated. Let $W \subset U$ be quasi-compact open. Then $t(s^{-1}(W))$ is an intersection of a nonempty family of quasi-compact open subsets of U .*

Proof. Note that $s^{-1}(W)$ is quasi-compact open in R . As a continuous map t maps the quasi-compact subset $s^{-1}(W)$ to a quasi-compact subset $t(s^{-1}(W))$. As t is flat and $s^{-1}(W)$ is closed under generalization, so is $t(s^{-1}(W))$, see (Morphisms, Lemma 28.26.8 and Topology, Lemma 5.18.5). Pick a quasi-compact open $W' \subset U$ containing $t(s^{-1}(W))$. By Properties, Lemma 27.2.4 we see that W' is a spectral space (here we use that U is quasi-separated). Then the lemma follows from Topology, Lemma 5.23.7 applied to $t(s^{-1}(W)) \subset W'$. \square

Lemma 38.17.4. *Assumptions and notation as in Lemma 38.17.3. There exists an R -invariant open $V \subset U$ and a quasi-compact open W' such that $W \subset V \subset W' \subset U$.*

Proof. Set $E = t(s^{-1}(W))$. Recall that E is set-theoretically R -invariant (Lemma 38.17.2). By Lemma 38.17.3 there exists a quasi-compact open W' containing E . Let $Z = U \setminus W'$ and consider $T = t(s^{-1}(Z))$. Observe that $Z \subset T$ and that $E \cap T = \emptyset$ because $s^{-1}(E) = t^{-1}(E)$ is disjoint from $s^{-1}(Z)$. Since T is the image of the closed subset $s^{-1}(Z) \subset R$ under the quasi-compact morphism $t : R \rightarrow U$ we see that any point ξ in the closure \bar{T} is the specialization of a point of T , see Morphisms, Lemma 28.6.5 (and Morphisms, Lemma 28.6.3 to see that the scheme theoretic image is the closure of the image). Say $\xi' \rightsquigarrow \xi$ with $\xi' \in T$. Suppose that $r \in R$ and $s(r) = \xi$. Since s is flat we can find a specialization $r' \rightsquigarrow r$ in R such that $s(r') = \xi'$ (Morphisms, Lemma 28.26.8). Then $t(r') \rightsquigarrow t(r)$. We conclude that $t(r') \in T$ as T is set-theoretically invariant by Lemma 38.17.2. Thus \bar{T} is a set-theoretically R -invariant closed subset and $V = U \setminus \bar{T}$ is the open we are looking for. It is contained in W' which finishes the proof. \square

38.18. Quotient sheaves

Let $\tau \in \{\text{Zariski, étale, fppf, smooth, syntomic}\}$. Let S be a scheme. Let $j : R \rightarrow U \times_S U$ be a pre-relation over S . Say U, R, S are objects of a τ -site Sch_τ (see Topologies, Section 33.2). Then we can consider the functors

$$h_U, h_R : (Sch/S)_\tau^{opp} \longrightarrow Sets.$$

These are sheaves, see Descent, Lemma 34.9.3. The morphism j induces a map $j : h_R \rightarrow h_U \times h_U$. For each object $T \in \text{Ob}((Sch/S)_\tau)$ we can take the equivalence relation \sim_T generated by $j(T) : R(T) \rightarrow U(T) \times U(T)$ and consider the quotient. Hence we get a presheaf

$$(38.18.0.1) \quad (Sch/S)_\tau^{opp} \longrightarrow Sets, \quad T \longmapsto U(T) / \sim_T$$

Definition 38.18.1. Let τ, S , and the pre-relation $j : R \rightarrow U \times_S U$ be as above. In this setting the *quotient sheaf* U/R associated to j is the sheafification of the presheaf (38.18.0.1) in the τ -topology. If $j : R \rightarrow U \times_S U$ comes from the action of a group scheme G/S on U as in Lemma 38.14.1 then we sometimes denote the quotient sheaf U/G .

This means exactly that the diagram

$$h_R \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} h_U \longrightarrow U/R$$

is a coequalizer diagram in the category of sheaves of sets on $(Sch/S)_\tau$. Using the Yoneda embedding we may view $(Sch/S)_\tau$ as a full subcategory of sheaves on $(Sch/S)_\tau$ and hence identify schemes with representable functors. Using this abuse of notation we will often depict the diagram above simply

$$R \begin{array}{c} \xrightarrow{s} \\ \xrightarrow{t} \end{array} U \longrightarrow U/R$$

We will mostly work with the fppf topology when considering quotient sheaves of groupoids/equivalence relations.

Definition 38.18.2. In the situation of Definition 38.18.1. We say that the pre-relation j has a *representable quotient* if the sheaf U/R is representable. We will say a groupoid (U, R, s, t, c) has a *representable quotient* if the quotient U/R with $j = (t, s)$ is representable.

The following lemma characterizes schemes M representing the quotient. It applies for example if $\tau = fppf$, $U \rightarrow M$ is flat, of finite presentation and surjective, and $R \cong U \times_M U$.

Lemma 38.18.3. *In the situation of Definition 38.18.1. Assume there is a scheme M , and a morphism $U \rightarrow M$ such that*

- (1) *the morphism $U \rightarrow M$ equalizes s, t ,*
- (2) *the morphism $U \rightarrow M$ induces a surjection of sheaves $h_U \rightarrow h_M$ in the τ -topology, and*
- (3) *the induced map $(t, s) : R \rightarrow U \times_M U$ induces a surjection of sheaves $h_R \rightarrow h_{U \times_M U}$ in the τ -topology.*

In this case M represents the quotient sheaf U/R .

Proof. Condition (1) says that $h_U \rightarrow h_M$ factors through U/R . Condition (2) says that $U/R \rightarrow h_M$ is surjective as a map of sheaves. Condition (3) says that $U/R \rightarrow h_M$ is injective as a map of sheaves. Hence the lemma follows. \square

The following lemma is wrong if we do not require j to be a pre-equivalence relation (but just a pre-relation say).

Lemma 38.18.4. *Let $\tau \in \{\text{Zariski}, \text{étale}, \text{fppf}, \text{smooth}, \text{syntomic}\}$. Let S be a scheme. Let $j : R \rightarrow U \times_S U$ be a pre-equivalence relation over S . Assume U, R, S are objects of a τ -site Sch_τ . For $T \in \text{Ob}((Sch/S)_\tau)$ and $a, b \in U(T)$ the following are equivalent:*

- (1) *a and b map to the same element of $(U/R)(T)$, and*
- (2) *there exists a τ -covering $\{f_i : T_i \rightarrow T\}$ of T and morphisms $r_i : T_i \rightarrow R$ such that $a \circ f_i = s \circ r_i$ and $b \circ f_i = t \circ r_i$.*

In other words, in this case the map of τ -sheaves

$$h_R \longrightarrow h_U \times_{U/R} h_U$$

is surjective.

Proof. Omitted. Hint: The reason this works is that the presheaf (38.18.0.1) in this case is really given by $T \mapsto U(T)/j(R(T))$ as $j(R(T)) \subset U(T) \times U(T)$ is an equivalence relation, see Definition 38.3.1. \square

Lemma 38.18.5. *Let $\tau \in \{\text{Zariski, étale, fppf, smooth, syntomic}\}$. Let S be a scheme. Let $j : R \rightarrow U \times_S U$ be a pre-equivalence relation over S and $g : U' \rightarrow U$ a morphism of schemes over S . Let $j' : R' \rightarrow U' \times_S U'$ be the restriction of j to U' . Assume U, U', R, S are objects of a τ -site Sch_τ . The map of quotient sheaves*

$$U'/R' \longrightarrow U/R$$

is injective. If g defines a surjection $h_{U'} \rightarrow h_U$ of sheaves in the τ -topology (for example if $\{g : U' \rightarrow U\}$ is a τ -covering), then $U'/R' \rightarrow U/R$ is an isomorphism.

Proof. Suppose $\xi, \xi' \in (U'/R')(T)$ are sections which map to the same section of U/R . Then we can find a τ -covering $\mathcal{T} = \{T_i \rightarrow T\}$ of T such that $\xi|_{T_i}, \xi'|_{T_i}$ are given by $a_i, a'_i \in U'(T_i)$. By Lemma 38.18.4 and the axioms of a site we may after refining \mathcal{T} assume there exist morphisms $r_i : T_i \rightarrow R$ such that $g \circ a_i = s \circ r_i$, $g \circ a'_i = t \circ r_i$. Since by construction $R' = R \times_{U \times_S U} (U' \times_S U')$ we see that $(r_i, (a_i, a'_i)) \in R'(T_i)$ and this shows that a_i and a'_i define the same section of U'/R' over T_i . By the sheaf condition this implies $\xi = \xi'$.

If $h_{U'} \rightarrow h_U$ is a surjection of sheaves, then of course $U'/R' \rightarrow U/R$ is surjective also. If $\{g : U' \rightarrow U\}$ is a τ -covering, then the map of sheaves $h_{U'} \rightarrow h_U$ is surjective, see Sites, Lemma 7.13.4. Hence $U'/R' \rightarrow U/R$ is surjective also in this case. \square

Lemma 38.18.6. *Let $\tau \in \{\text{Zariski, étale, fppf, smooth, syntomic}\}$. Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ a morphism of schemes over S . Let (U', R', s', t', c') be the restriction of (U, R, s, t, c) to U' . Assume U, U', R, S are objects of a τ -site Sch_τ . The map of quotient sheaves*

$$U'/R' \longrightarrow U/R$$

is injective. If the composition

$$U' \times_{g, U, t} R \begin{array}{c} \xrightarrow{h} \\ \xrightarrow{\text{pr}_1} R \xrightarrow{s} \end{array} U$$

defines a surjection of sheaves in the τ -topology then the map is bijective. This holds for example if $\{h : U' \times_{g, U, t} R \rightarrow U\}$ is a τ -covering, or if $U' \rightarrow U$ defines a surjection of sheaves in the τ -topology, or if $\{g : U' \rightarrow U\}$ is a covering in the τ -topology.

Proof. Injectivity follows on combining Lemmas 38.11.2 and 38.18.5. To see surjectivity (see Sites, Section 7.12 for a characterization of surjective maps of sheaves) we argue as follows. Suppose that T is a scheme and $\sigma \in U/R(T)$. There exists a covering $\{T_i \rightarrow T\}$ such that $\sigma|_{T_i}$ is the image of some element $f_i \in U(T_i)$. Hence we may assume that σ is the image of $f \in U(T)$. By the assumption that h is a surjection of sheaves, we can find a τ -covering $\{\varphi_i : T_i \rightarrow T\}$ and morphisms $f_i : T_i \rightarrow U' \times_{g, U, t} R$ such that $f \circ \varphi_i = h \circ f_i$. Denote $f'_i = \text{pr}_0 \circ f_i : T_i \rightarrow U'$. Then we see that $f'_i \in U'(T_i)$ maps to $g \circ f'_i \in U(T_i)$ and that $g \circ f'_i \sim_{T_i} h \circ f_i = f \circ \varphi_i$ notation as in (38.18.0.1). Namely, the element of $R(T_i)$ giving the relation is $\text{pr}_1 \circ f_i$.

This means that the restriction of σ to T_i is in the image of $U'/R'(T_i) \rightarrow U/R(T_i)$ as desired.

If $\{h\}$ is a τ -covering, then it induces a surjection of sheaves, see Sites, Lemma 7.13.4. If $U' \rightarrow U$ is surjective, then also h is surjective as s has a section (namely the neutral element e of the groupoid scheme). \square

Lemma 38.18.7. *Let S be a scheme. Let $f : (U, R, j) \rightarrow (U', R', j')$ be a morphism between equivalence relations over S . Assume that*

$$\begin{array}{ccc} R & \longrightarrow & R' \\ s \downarrow & & \downarrow s' \\ U & \xrightarrow{f} & U' \end{array}$$

is cartesian. For any $\tau \in \{\text{Zariski, étale, fppf, smooth, syntomic}\}$ the diagram

$$\begin{array}{ccc} U & \longrightarrow & U/R \\ \downarrow & & \downarrow f \\ U' & \longrightarrow & U'/R' \end{array}$$

is a fibre product square of τ -sheaves.

Proof. By Lemma 38.18.4 the quotient sheaves have a simple description which we will use below without further mention. We first show that

$$U \longrightarrow U' \times_{U'/R'} U/R$$

is injective. Namely, assume $a, b \in U(T)$ map to the same element on the right hand side. Then $f(a) = f(b)$. After replacing T by the members of a τ -covering we may assume that there exists an $r \in R(T)$ such that $a = s(r)$ and $b = t(r)$. Then $r' = f(r)$ is a T -valued point of R' with $s'(r') = t'(r')$. Hence $r' = e'(f(a))$ (where e' is the identity of the groupoid scheme associated to j' , see Lemma 38.11.3). Because the first diagram of the lemma is cartesian this implies that r has to equal $e(a)$. Thus $a = b$.

Finally, we show that the displayed arrow is surjective. Let T be a scheme over S and let (a', \bar{b}) be a section of the sheaf $U' \times_{U'/R'} U/R$ over T . After replacing T by the members of a τ -covering we may assume that \bar{b} is the class of an element $b \in U(T)$. After replacing T by the members of a τ -covering we may assume that there exists an $r' \in R'(T)$ such that $a' = t'(r')$ and $s'(r') = f(b)$. Because the first diagram of the lemma is cartesian we can find $r \in R(T)$ such that $s(r) = b$ and $f(r) = r'$. Then it is clear that $a = t(r) \in U(T)$ is a section which maps to (a', \bar{b}) . \square

38.19. Descent in terms of groupoids

Cartesian morphisms are defined as follows.

Definition 38.19.1. Let S be a scheme. Let $f : (U', R', s', t', c') \rightarrow (U, R, s, t, c)$ be a morphism of groupoid schemes over S . We say f is *cartesian*, or that (U', R', s', t', c')

is cartesian over (U, R, s, t, c) , if the diagram

$$\begin{array}{ccc} R' & \xrightarrow{\quad} & R \\ s' \downarrow & & \downarrow s \\ U' & \xrightarrow{\quad} & U \end{array}$$

is a fibre square in the category of schemes. A *morphism of groupoid schemes cartesian over (U, R, s, t, c)* is a morphism of groupoid schemes compatible with the structure morphisms towards (U, R, s, t, c) .

Cartesian morphisms are related to descent data. First we prove a general lemma describing the category of cartesian groupoid schemes over a fixed groupoid scheme.

Lemma 38.19.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . The category of groupoid schemes cartesian over (U, R, s, t, c) is equivalent to the category of pairs (V, φ) where V is a scheme over U and*

$$\varphi : V \times_{U,t} R \longrightarrow R \times_{s,U} V$$

is an isomorphism over R such that $e^*\varphi = id_V$ and such that

$$c^*\varphi = pr_1^*\varphi \circ pr_0^*\varphi$$

as morphisms of schemes over $R \times_{s,U,t} R$.

Proof. The pullback notation in the lemma signifies base change. The displayed formula makes sense because

$$(R \times_{s,U,t} R) \times_{pr_1,R,pr_1} (V \times_{U,t} R) = (R \times_{s,U,t} R) \times_{pr_0,R,pr_0} (R \times_{s,U} V)$$

as schemes over $R \times_{s,U,t} R$.

Given (V, φ) we set $U' = V$ and $R' = V \times_{U,t} R$. We set $t' : R' \rightarrow U'$ equal to the projection $V \times_{U,t} R \rightarrow V$. We set s' equal to φ followed by the projection $R \times_{s,U} V \rightarrow V$. We set c' equal to the composition

$$\begin{aligned} R' \times_{s',U',t'} R' &\xrightarrow{\varphi,1} (R \times_{s,U} V) \times_V (V \times_{U,t} R) \\ &\rightarrow R \times_{s,U} V \times_{U,t} R \\ &\xrightarrow{\varphi^{-1},1} V \times_{U,t} (R \times_{s,U,t} R) \\ &\xrightarrow{1,c} V \times_{U,t} R = R' \end{aligned}$$

A computation, which we omit shows that we obtain a groupoid scheme over (U, R, s, t, c) . It is clear that this groupoid scheme is cartesian over (U, R, s, t, c) .

Conversely, given $f : (U', R', s', t', c') \rightarrow (U, R, s, t, c)$ cartesian then the morphisms

$$U' \times_{U,t} R \xleftarrow{t',f} R' \xrightarrow{f,s'} R \times_{s,U} U'$$

are isomorphisms and we can set $V = U'$ and φ equal to the composition $(f, s') \circ (t', f)^{-1}$. We omit the proof that φ satisfies the conditions in the lemma. We omit the proof that these constructions are mutually inverse. \square

Let S be a scheme. Let $f : X \rightarrow Y$ be a morphism of schemes over S . Then we obtain a groupoid scheme $(X, X \times_Y X, pr_1, pr_0, c)$ over S . Namely, $j : X \times_Y X \rightarrow X \times_S X$ is an equivalence relation and we can take the associated groupoid, see Lemma 38.11.3.

Lemma 38.19.3. *Let S be a scheme. Let $f : X \rightarrow Y$ be a morphism of schemes over S . The construction of Lemma 38.19.2 determines an equivalence*

$$\begin{array}{ccc} \text{category of groupoids schemes} & \longrightarrow & \text{category of descent data} \\ \text{cartesian over } (X, X \times_Y X, \dots) & & \text{relative to } X/Y \end{array}$$

Proof. This is clear from Lemma 38.19.2 and the definition of descent data on schemes in Descent, Definition 34.30.1. □

38.20. Separation conditions

This really means conditions on the morphism $j : R \rightarrow U \times_S U$ when given a groupoid (U, R, s, t, c) over S . As in the previous section we first formulate the corresponding diagram.

Lemma 38.20.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . Let $G \rightarrow U$ be the stabilizer group scheme. The commutative diagram*

$$\begin{array}{ccccc} R & \xrightarrow{f \mapsto (f, s(f))} & R \times_{s,U} U & \longrightarrow & U \\ \downarrow \Delta_{R/U \times_S U} & & \downarrow & & \downarrow \\ R \times_{(U \times_S U)} R & \xrightarrow{(f,g) \mapsto (f, f^{-1} \circ g)} & R \times_{s,U} G & \longrightarrow & G \end{array}$$

the two left horizontal arrows are isomorphisms and the right square is a fibre product square.

Proof. Omitted. Exercise in the definitions and the functorial point of view in algebraic geometry. □

Lemma 38.20.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . Let $G \rightarrow U$ be the stabilizer group scheme.*

- (1) *The following are equivalent*
 - (a) $j : R \rightarrow U \times_S U$ is separated,
 - (b) $G \rightarrow U$ is separated, and
 - (c) $e : U \rightarrow G$ is a closed immersion.
- (2) *The following are equivalent*
 - (a) $j : R \rightarrow U \times_S U$ is quasi-separated,
 - (b) $G \rightarrow U$ is quasi-separated, and
 - (c) $e : U \rightarrow G$ is quasi-compact.

Proof. The group scheme $G \rightarrow U$ is the base change of $R \rightarrow U \times_S U$ by the diagonal morphism $U \rightarrow U \times_S U$, see Lemma 38.15.1. Hence if j is separated (resp. quasi-separated), then $G \rightarrow U$ is separated (resp. quasi-separated). (See Schemes, Lemma 25.21.13). Thus (a) \Rightarrow (b) in both (1) and (2).

If $G \rightarrow U$ is separated (resp. quasi-separated), then the morphism $U \rightarrow G$, as a section of the structure morphism $G \rightarrow U$ is a closed immersion (resp. quasi-compact), see Schemes, Lemma 25.21.12. Thus (b) \Rightarrow (a) in both (1) and (2).

By the result of Lemma 38.20.1 (and Schemes, Lemmas 25.18.2 and 25.19.3) we see that if e is a closed immersion (resp. quasi-compact) $\Delta_{R/U \times_S U}$ is a closed immersion (resp. quasi-compact). Thus (c) \Rightarrow (a) in both (1) and (2). □

38.21. Finite flat groupoids, affine case

Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine. In this case we get two ring maps $s^\#, t^\# : A \rightarrow B$. Let C be the equalizer of $s^\#$ and $t^\#$. In a formula

$$(38.21.0.1) \quad C = \{a \in A \mid t^\#(a) = s^\#(a)\}.$$

We will sometimes call this the *ring of R -invariant functions on U* . What properties does $M = \text{Spec}(C)$ have? The first observation is that the diagram

$$\begin{array}{ccc} R & \xrightarrow{\quad} & U \\ t \downarrow & & \downarrow \\ U & \xrightarrow{\quad} & M \end{array}$$

is commutative, i.e., the morphism $U \rightarrow M$ equalizes s, t . Moreover, if T is any affine scheme, and if $U \rightarrow T$ is a morphism which equalizes s, t , then $U \rightarrow T$ factors through $U \rightarrow M$. In other words, $U \rightarrow M$ is a coequalizer in the category of affine schemes.

We would like to find conditions that guarantee the morphism $U \rightarrow M$ is really a “quotient” in the category of schemes. We will discuss this at length elsewhere (insert future reference here); here we just discuss some special cases. Namely, we will focus on the case where s, t are finite locally free.

Example 38.21.1. Let k be a field. Let $U = \text{GL}_{2,k}$. Let $B \subset \text{GL}_2$ be the closed subgroup scheme of upper triangular matrices. Then the quotient sheaf $\text{GL}_{2,k}/B$ (in the Zariski, étale or fppf topology, see Definition 38.18.1) is representable by the projective line: $\mathbf{P}^1 = \text{GL}_{2,k}/B$. (Details omitted.) On the other hand, the ring of invariant functions in this case is just k . Note that in this case the morphisms $s, t : R = \text{GL}_{2,k} \times_k B \rightarrow \text{GL}_{2,k} = U$ are smooth of relative dimension 3.

Recall that in Exercises, Exercises 83.15.6 and 83.15.7 we have defined the determinant and the norm for finitely locally free modules and finite locally free ring extensions. If $\varphi : A \rightarrow B$ is a finite locally free ring map, then we will denote $\text{Norm}_\varphi(b) \in A$ the norm of $b \in B$.

Lemma 38.21.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine, and $s, t : R \rightarrow U$ finite locally free. Let C be as in (38.21.0.1). Let $f \in A$. Then $\text{Norm}_{s^\#} (t^\#(f)) \in C$.*

Proof. Consider the commutative diagram

$$\begin{array}{ccccc} & & U & & \\ & t \nearrow & & \nwarrow t & \\ R & \xleftarrow{\text{pr}_0} & R \times_{s,U,t} R & \xrightarrow{c} & R \\ s \downarrow & & \downarrow \text{pr}_1 & & \downarrow s \\ U & \xleftarrow{t} & R & \xrightarrow{s} & U \end{array}$$

of Lemma 38.11.4. Think of $f \in \Gamma(U, \mathcal{O}_U)$. The commutativity of the top part of the diagram shows that $\text{pr}_0^\#(t^\#(f)) = c^\#(t^\#(f))$ as elements of $\Gamma(R \times_{s,U,t} R, \mathcal{O})$. Looking at the right lower cartesian square the compatibility of the norm construction with

base change shows that $s^\sharp(\text{Norm}_{s^\sharp}(t^\sharp(f))) = \text{Norm}_{\text{pr}_1}(c^\sharp(t^\sharp(f)))$. Similarly we get $t^\sharp(\text{Norm}_{s^\sharp}(t^\sharp(f))) = \text{Norm}_{\text{pr}_1}(\text{pr}_0^\sharp(t^\sharp(f)))$. Hence by the first equality of this proof we see that $s^\sharp(\text{Norm}_{s^\sharp}(t^\sharp(f))) = t^\sharp(\text{Norm}_{s^\sharp}(t^\sharp(f)))$ as desired. \square

Lemma 38.21.3. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $s, t : R \rightarrow U$ finite locally free. Then*

$$U = \coprod_{r \geq 1} U_r$$

is a disjoint union of R -invariant opens such that the restriction R_r of R to U_r has the property that $s, t : R_r \rightarrow U_r$ are finite locally free of rank 1.

Proof. By Morphisms, Lemma 28.46.5 there exists a decomposition $U = \coprod_{r \geq 0} U_r$ such that $s : s^{-1}(U_r) \rightarrow U_r$ is finite locally free of rank r . As s is surjective we see that $U_0 = \emptyset$. Note that $u \in U_r \Leftrightarrow$ the scheme theoretic fibre $s^{-1}(u)$ has degree r over $\kappa(u)$. Now, if $z \in R$ with $s(z) = u$ and $t(z) = u'$ then $\text{pr}_1^{-1}(z)$ see diagram of Lemma 38.11.4 is a scheme over $\kappa(z)$ which is the base change of both $s^{-1}(u)$ and $s^{-1}(u')$ via $\kappa(u) \rightarrow \kappa(z)$ and $\kappa(u') \rightarrow \kappa(z)$ by the properties of that diagram. Hence we see that the open subsets U_r are R -invariant. In particular the restriction of R to U_r is just $s^{-1}(U_r)$ and $s : R_r \rightarrow U_r$ is finite locally free of rank r . As $t : R_r \rightarrow U_r$ is isomorphic to s by the inverse of R_r we see that it has also rank r . \square

Lemma 38.21.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine, and $s, t : R \rightarrow U$ finite locally free. Let $C \subset A$ be as in (38.21.0.1). Then A is integral over C .*

Proof. First, by Lemma 38.21.3 we know that (U, R, s, t, c) is a disjoint union of groupoid schemes (U_r, R_r, s, t, c) such that each $s, t : R_r \rightarrow U_r$ has constant rank r . As U is quasi-compact, we have $U_r = \emptyset$ for almost all r . It suffices to prove the lemma for each (U_r, R_r, s, t, c) and hence we may assume that s, t are finite locally free of rank r .

Assume that s, t are finite locally free of rank r . Let $f \in A$. Consider the element $x - f \in A[x]$, where we think of x as the coordinate on \mathbf{A}^1 . Since

$$(U \times \mathbf{A}^1, R \times \mathbf{A}^1, s \times \text{id}_{\mathbf{A}^1}, t \times \text{id}_{\mathbf{A}^1}, c \times \text{id}_{\mathbf{A}^1})$$

is also a groupoid scheme with finite source and target, we may apply Lemma 38.21.2 to it and we see that $P(x) = \text{Norm}_{s^\sharp}(t^\sharp(x - f))$ is an element of $C[x]$. Because $s^\sharp : A \rightarrow B$ is finite locally free of rank r we see that P is monic of degree r . Moreover $P(f) = 0$ by Cayley-Hamilton (Algebra, Lemma 10.15.1). \square

Lemma 38.21.5. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine, and $s, t : R \rightarrow U$ finite locally free. Let $C \subset A$ be as in (38.21.0.1). Let $C \rightarrow C'$ be a ring map, and set $U' = \text{Spec}(A \otimes_C C')$, $R' = \text{Spec}(B \otimes_C C')$. Then*

- (1) *the maps s, t, c induce maps s', t', c' such that (U', R', s', t', c') is a groupoid scheme, and*
- (2) *there is a canonical map $\varphi : C' \rightarrow C^1$ of C' into the R' -invariant functions C^1 on U' with the properties*
 - (a) *for every $f \in C^1$ there exists an $n > 0$ such that f^n is in the image of φ , and*

- (b) for every $f \in \text{Ker}(\varphi)$ there exists an $n > 0$ such that $f^n = 0$.
- (3) if $C \rightarrow C'$ is flat then φ is an isomorphism.

Proof. The proof of part (1) is omitted. Let us denote $A' = A \otimes_C C'$ and $B' = B \otimes_C C'$. Then we have

$$C^1 = \{x \in A' \mid (t')^\sharp(x) = (s')^\sharp(x)\} = \{a \in A \otimes_C C' \mid t^\sharp \otimes 1(x) = s^\sharp \otimes 1(x)\}.$$

In other words, C^1 is the kernel of the difference map $(t^\sharp - s^\sharp) \otimes 1$ which is just the base change of the C -linear map $t^\sharp - s^\sharp : A \rightarrow B$ by $C \rightarrow C'$. Hence (3) follows.

Proof of part (2)(b). Since $C \rightarrow A$ is integral (Lemma 38.21.4) and injective we see that $\text{Spec}(A) \rightarrow \text{Spec}(C)$ is surjective, see Algebra, Lemma 10.35.15. Thus also $\text{Spec}(A') \rightarrow \text{Spec}(C')$ is surjective as a base change of a surjective morphism (Morphisms, Lemma 28.11.4). Hence $\text{Spec}(C^1) \rightarrow \text{Spec}(C')$ is surjective also. This implies that the kernel of φ is contained in the radical of the ring C' , i.e., (2)(b) holds.

Proof of part (2)(a). By Lemma 38.21.3 we know that A is a finite product of rings A_r and B is a finite product of rings B_r such that the groupoid scheme decomposes accordingly (see the proof of Lemma 38.21.4). Then also C is a product of rings C_r and correspondingly C' decomposes as a product. Hence we may and do assume that the ring maps $s^\sharp, t^\sharp : A \rightarrow B$ are finite locally free of a fixed rank r . Let $f \in C^1 \subset A' = A \otimes_C C'$. We may replace C' by a finitely generated C -subalgebra of C' and hence we may assume that $C' = C[X_1, \dots, X_n]/I$ for some ideal I . Choose a lift $\tilde{f} \in A \otimes_C C[X_i] = A[X_i]$ of the element f . Note that $f^r = \text{Norm}_{(s')^\sharp}((t')^\sharp(f))$ in A as $t^\sharp(f) = s^\sharp(f)$. Hence we see that

$$h = \text{Norm}_{s^\sharp \otimes 1}(t^\sharp \otimes 1(f)) \in A[X_i]$$

is invariant according to Lemma 38.21.2 and maps to f^r in A' . Since $C \rightarrow C[X_i]$ is flat we see from (3) that $h \in C[X_i]$. Hence it follows that f^r is in the image of φ . □

Lemma 38.21.6. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine, and $s, t : R \rightarrow U$ finite locally free. Let $C \subset A$ be as in (38.21.0.1). Then $U \rightarrow M = \text{Spec}(C)$ has the following properties:*

- (1) *the map on points $|U| \rightarrow |M|$ is surjective and $u_0, u_1 \in |U|$ map to the same point if and only if there exists a $r \in |R|$ with $t(r) = u_0$ and $s(r) = u_1$, in a formula*

$$|M| = |U|/|R|$$

- (2) *for any algebraically closed field k we have*

$$M(k) = U(k)/R(k)$$

Proof. Let k be an algebraically closed field. Since $C \rightarrow A$ is integral (Lemma 38.21.4) and injective we see that $\text{Spec}(A) \rightarrow \text{Spec}(C)$ is surjective, see Algebra, Lemma 10.35.15. Thus $|M| \rightarrow |U|$ is surjective. Let $C \rightarrow k$ be a ring map. Since surjective morphisms are preserved under base change (Morphisms, Lemma 28.11.4) we see that $A \otimes_C k$ is not zero. Now $k \subset A \otimes_C k$ is a nonzero integral extension. Hence any residue field of $A \otimes_C k$ is an algebraic extension of k , hence equal to k . Thus we see that $U(k) \rightarrow M(k)$ is surjective.

Let $a_0, a_1 : A \rightarrow k$ be ring maps. If there exists a ring map $b : B \rightarrow k$ such that $a_0 = b \circ t^\sharp$ and $a_1 = b \circ s^\sharp$ then we see that $a_0|_C = a_1|_C$ by definition. Conversely, suppose that $a_0|_C = a_1|_C$. Let us name this algebra map $c : C \rightarrow k$. Consider the diagram

We are trying to construct the dotted arrow, and if we do then part (2) follows, which in turn implies part (1). Since $A \rightarrow B$ is finite and faithfully flat there exist finitely many ring maps $b_1, \dots, b_n : B \rightarrow k$ such that $b_i \circ s^\sharp = a_1$. If the dotted arrow does not exist, then we see that none of the $a'_i = b_i \circ t^\sharp, i = 1, \dots, n$ is equal to a_0 . Hence the maximal ideals

$$\mathfrak{m}'_i = \text{Ker}(a'_i \otimes 1 : A \otimes_C k \rightarrow k)$$

of $A \otimes_C k$ are distinct from $\mathfrak{m} = \text{Ker}(a_0 \otimes 1 : A \otimes_C k \rightarrow k)$. By Algebra, Lemma 10.14.2 we would get an element $f \in A \otimes_C k$ with $f \in \mathfrak{m}$, but $f \notin \mathfrak{m}'_i$ for $i = 1, \dots, n$. Consider the norm

$$g = \text{Norm}_{s^\sharp \otimes 1}(t^\sharp \otimes 1(f)) \in A \otimes_C k$$

By Lemma 38.21.2 this lies in the invariants $C^1 \subset A \otimes_C k$ of the base change groupoid (base change via the map $c : C \rightarrow k$). On the one hand, $a_1(g) \in k^*$ since the value of $t^\sharp(f)$ at all the points (which correspond to b_1, \dots, b_n) lying over a_1 is invertible (insert future reference on property determinant here). On the other hand, since $f \in \mathfrak{m}$, we see that f is not a unit, hence $t^\sharp(f)$ is not a unit (as $t^\sharp \otimes 1$ is faithfully flat), hence its norm is not a unit (insert future reference on property determinant here). We conclude that C^1 contains an element which is not nilpotent and not a unit. We will now show that this leads to a contradiction. Namely, apply Lemma 38.21.5 to the map $c : C \rightarrow C' = k$, then we see that the map of k into the invariants C^1 is injective and moreover, that for any element $x \in C^1$ there exists an integer $n > 0$ such that $x^n \in k$. Hence every element of C^1 is either a unit or nilpotent. □

Lemma 38.21.7. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume*

- (1) $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine, and
- (2) there exist elements $x_i \in A, i \in I$ such that $B = \bigoplus_{i \in I} s^\sharp(A)t^\sharp(x_i)$.

Then $A = \bigoplus_{i \in I} Cx_i$, and $B \cong A \otimes_C A$ where $C \subset A$ is the R -invariant functions on U as in (38.21.0.1).

Proof. During this proof we will write $s, t : A \rightarrow B$ instead of s^\sharp, t^\sharp , and similarly $c : B \rightarrow B \otimes_{s, A, t} B$. We write $p_0 : B \rightarrow B \otimes_{s, A, t} B, b \mapsto b \otimes 1$ and $p_1 : B \rightarrow B \otimes_{s, A, t} B, b \mapsto 1 \otimes b$. By Lemma 38.11.5 and the definition of C we have the following

commutative diagram

$$\begin{array}{ccccc}
 B \otimes_{s,A,t} B & \xleftarrow{c} & B & \xleftarrow{t} & A \\
 \uparrow p_1 & & \uparrow s & & \uparrow \\
 B & \xleftarrow{s} & A & \xleftarrow{t} & C
 \end{array}$$

Moreover the two left squares are cocartesian in the category of rings, and the top row is isomorphic to the diagram

$$B \otimes_{t,A,t} B \xleftarrow{p_1} B \xleftarrow{p_0} A$$

which is an equalizer diagram according to Descent, Lemma 34.3.6 because condition (2) implies in particular that s (and hence also then isomorphic arrow t) is faithfully flat. The lower row is an equalizer diagram by definition of C . We can use the x_i and get a commutative diagram

$$\begin{array}{ccccc}
 B \otimes_{s,A,t} B & \xleftarrow{c} & B & \xleftarrow{t} & A \\
 \uparrow p_1 & & \uparrow s & & \uparrow \\
 \bigoplus_{i \in I} Bx_i & \xleftarrow{s} & \bigoplus_{i \in I} Ax_i & \xleftarrow{t} & \bigoplus_{i \in I} Cx_i
 \end{array}$$

where in the right vertical arrow we map x_i to x_i , in the middle vertical arrow we map x_i to $t(x_i)$ and in the left vertical arrow we map x_i to $c(t(x_i)) = t(x_i) \otimes 1 = p_0(t(x_i))$ (equality by the commutativity of the top part of the diagram in Lemma 38.11.4). Then the diagram commutes. Moreover the middle vertical arrow is an isomorphism by assumption. Since the left two squares are cocartesian we conclude that also the left vertical arrow is an isomorphism. On the other hand, the horizontal rows are exact (i.e., they are equalizers). Hence we conclude that also the right vertical arrow is an isomorphism. \square

Proposition 38.21.8. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume*

- (1) $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine,
- (2) $s, t : R \rightarrow U$ finite locally free, and
- (3) $j = (t, s)$ is an equivalence.

In this case, let $C \subset A$ be as in (38.21.0.1). Then $U \rightarrow M = \text{Spec}(C)$ is finite locally free and $R = U \times_M U$. Moreover, M represents the quotient sheaf U/R in the fppf topology (see Definition 38.18.1).

Proof. During this proof we use the notation $s, t : A \rightarrow B$ instead of the notation s^\sharp, t^\sharp . By Lemma 38.18.3 it suffices to show that $C \rightarrow A$ is finite locally free and that the map

$$t \otimes s : A \otimes_C A \rightarrow B$$

is an isomorphism. First, note that j is a monomorphism, and also finite (since already s and t are finite). Hence we see that j is a closed immersion by Morphisms, Lemma 28.44.13. Hence $A \otimes_C A \rightarrow B$ is surjective.

We will perform base change by flat ring maps $C \rightarrow C'$ as in Lemma 38.21.5, and we will use that formation of invariants commutes with flat base change, see

part (3) of the lemma cited. We will show below that for every prime $\mathfrak{p} \subset C$, there exists a local flat ring map $C_{\mathfrak{p}} \rightarrow C'_{\mathfrak{p}}$ such that the result holds after a base change to $C'_{\mathfrak{p}}$. This implies immediately that $A \otimes_C A \rightarrow B$ is injective (use Algebra, Lemma 10.23.1). It also implies that $C \rightarrow A$ is flat, by combining Algebra, Lemmas 10.38.16, 10.38.19, and 10.38.7. Then since $U \rightarrow \text{Spec}(C)$ is surjective also (Lemma 38.21.6) we conclude that $C \rightarrow A$ is faithfully flat. Then the isomorphism $B \cong A \otimes_C A$ implies that A is a finitely presented C -module, see Algebra, Lemma 10.80.2. Hence A is finite locally free over C , see Algebra, Lemma 10.75.2.

By Lemma 38.21.3 we know that A is a finite product of rings A_r and B is a finite product of rings B_r such that the groupoid scheme decomposes accordingly (see the proof of Lemma 38.21.4). Then also C is a product of rings C_r and correspondingly C' decomposes as a product. Hence we may and do assume that the ring maps $s, t : A \rightarrow B$ are finite locally free of a fixed rank r .

The local ring maps $C_{\mathfrak{p}} \rightarrow C'_{\mathfrak{p}}$ we are going to use are any local flat ring maps such that the residue field of $C'_{\mathfrak{p}}$ is infinite. By Algebra, Lemma 10.148.1 such local ring maps exist.

Assume C is a local ring with maximal ideal \mathfrak{m} and infinite residue field, and assume that $s, t : A \rightarrow B$ is finite locally free of constant rank $r > 0$. Since $C \subset A$ is integral (Lemma 38.21.4) all primes lying over \mathfrak{m} are maximal, and all maximal ideals of A lie over \mathfrak{m} . Similarly for $C \subset B$. Pick a maximal ideal \mathfrak{m}' of A lying over \mathfrak{m} (exists by Lemma 38.21.6). Since $t : A \rightarrow B$ is finite locally free there exist at most finitely many maximal ideals of B lying over \mathfrak{m}' . Hence we conclude (by Lemma 38.21.6 again) that A has finitely many maximal ideals, i.e., A is semi-local. This in turn implies that B is semi-local as well. OK, and now, because $t \otimes s : A \otimes_C A \rightarrow B$ is surjective, we can apply Algebra, Lemma 10.75.7 to the ring map $C \rightarrow A$, the A -module $M = B$ (seen as an A -module via t) and the C -submodule $s(A) \subset B$. This lemma implies that there exist $x_1, \dots, x_r \in A$ such that M is free over A on the basis $s(x_1), \dots, s(x_r)$. Hence we conclude that $C \rightarrow A$ is finite free and $B \cong A \otimes_C A$ by applying Lemma 38.21.7. \square

38.22. Finite flat groupoids

In this section we prove a lemma that will help to show that the quotient of a scheme by a finite flat equivalence relation is a scheme, provided that each equivalence class is contained in an affine. See Properties of Spaces, Proposition 48.11.1.

Lemma 38.22.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume s, t are finite locally free. Let $u \in U$ be a point such that $t(s^{-1}(\{u\}))$ is contained in an affine open of U . Then there exists an R -invariant affine open neighbourhood of u in U .*

Proof. Since s is finite locally free it has finite fibres. Hence $t(s^{-1}(\{u\})) = \{u_1, \dots, u_n\}$ is a finite set. Note that $u \in \{u_1, \dots, u_n\}$. Let $W \subset U$ be an affine open containing $\{u_1, \dots, u_n\}$, in particular $u \in W$. Consider $Z = R \setminus s^{-1}(W) \cap t^{-1}(W)$. This is a closed subset of R . The image $t(Z)$ is a closed subset of U which can be loosely described as the set of points of U which are R -equivalent to a point of $U \setminus W$. Hence $W' = U \setminus t(Z)$ is an R -invariant, open subscheme of U contained in W , and $\{u_1, \dots, u_n\} \subset W'$. Picture

$$\{u_1, \dots, u_n\} \subset W' \subset W \subset U.$$

Let $f \in \Gamma(W, \mathcal{O}_W)$ be an element such that $\{u_1, \dots, u_n\} \subset D(f) \subset W'$. Such an f exists by Algebra, Lemma 10.14.2. By our choice of W' we have $s^{-1}(W') \subset t^{-1}(W)$, and hence we get a diagram

$$\begin{array}{ccc} s^{-1}(W') & \xrightarrow{t} & W \\ \downarrow s & & \\ W' & & \end{array}$$

The vertical arrow is finite locally free by assumption. Set

$$g = \text{Norm}_s(t^\#f) \in \Gamma(W', \mathcal{O}_{W'})$$

By construction g is a function on W' which is nonzero in u , as $t^\#(f)$ is nonzero in each of the points of R lying over u , since f is nonzero in u_1, \dots, u_n . Similarly, $D(g) \subset W'$ is equal to the set of points w such that f is not zero in any of the points equivalent to w . This means that $D(g)$ is an R -invariant affine open of W' . The final picture is

$$\{u_1, \dots, u_n\} \subset D(g) \subset D(f) \subset W' \subset W \subset U$$

and hence we win. \square

CHAPTER 39

More on Groupoid Schemes

39.1. Introduction

This chapter is devoted to advanced topics on groupoid schemes. Even though the results are stated in terms of groupoid schemes, the reader should keep in mind the 2-cartesian diagram

$$(39.1.0.1) \quad \begin{array}{ccc} R & \longrightarrow & U \\ \downarrow & & \downarrow \\ U & \longrightarrow & [U/R] \end{array}$$

where $[U/R]$ is the quotient stack, see Groupoids in Spaces, Remark 60.19.4. Many of the results are motivated by thinking about this diagram. See for example the beautiful paper [KM97] by Keel and Mori.

39.2. Notation

We continue to abide by the conventions and notation introduced in Groupoids, Section 38.2.

39.3. Useful diagrams

We briefly restate the results of Groupoids, Lemmas 38.11.4 and 38.11.5 for easy reference in this chapter. Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . In the commutative diagram

$$(39.3.0.2) \quad \begin{array}{ccccc} & & U & & \\ & \swarrow t & & \nwarrow t & \\ R & & R \times_{s,U,t} R & & R \\ \swarrow \text{pr}_0 & & \downarrow \text{pr}_1 & & \searrow c \\ U & \xleftarrow{t} & R & \xrightarrow{s} & U \\ \downarrow s & & & & \downarrow s \end{array}$$

the two lower squares are fibre product squares. Moreover, the triangle on top (which is really a square) is also cartesian.

The diagram

$$(39.3.0.3) \quad \begin{array}{ccccc} R \times_{t,U,t} R & \xrightarrow{\text{pr}_1} & R & \xrightarrow{t} & U \\ \text{pr}_0 \times c \circ (i,1) \downarrow & \xrightarrow{\text{pr}_0} & \downarrow \text{id}_R & & \downarrow \text{id}_U \\ R \times_{s,U,t} R & \xrightarrow{c} & R & \xrightarrow{t} & U \\ \text{pr}_1 \downarrow & \xrightarrow{\text{pr}_0} & \downarrow s & & \\ R & \xrightarrow{s} & U & \xrightarrow{t} & \end{array}$$

is commutative. The two top rows are isomorphic via the vertical maps given. The two lower left squares are cartesian.

39.4. Sheaf of differentials

The following lemma is the analogue of Groupoids, Lemma 38.6.3.

Lemma 39.4.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . The sheaf of differentials of R seen as a scheme over U via t is a quotient of the pullback via t of the conormal sheaf of the immersion $e : U \rightarrow R$. In a formula: there is a canonical surjection $t^* \mathcal{C}_{U/R} \rightarrow \Omega_{R/U}$. If s is flat, then this map is an isomorphism.*

Proof. Note that $e : U \rightarrow R$ is an immersion as it is a section of the morphism s , see Schemes, Lemma 25.21.12. Consider the following diagram

$$\begin{array}{ccc} R & \xrightarrow{(1,i)} & R \times_{s,U,t} R \\ \downarrow t & & \downarrow c \\ U & \xrightarrow{e} & R \end{array} \quad \begin{array}{ccc} R & \xrightarrow{(\text{pr}_0, i \circ \text{pr}_1)} & R \times_{t,U,t} R \end{array}$$

The square on the left is cartesian, because if $a \circ b = e$, then $b = i(a)$. The composition of the horizontal maps is the diagonal morphism of $t : R \rightarrow U$. The right top horizontal arrow is an isomorphism. Hence since $\Omega_{R/U}$ is the conormal sheaf of the composition it is isomorphic to the conormal sheaf of $(1, i)$. By Morphisms, Lemma 28.33.4 we get the surjection $t^* \mathcal{C}_{U/R} \rightarrow \Omega_{R/U}$ and if c is flat, then this is an isomorphism. Since c is a base change of s by the properties of Diagram (39.3.0.3) we conclude that if s is flat, then c is flat, see Morphisms, Lemma 28.26.7. \square

39.5. Properties of groupoids

Let (U, R, s, t, c) be a groupoid scheme. The idea behind the results in this section is that $s : R \rightarrow U$ is a base changes of the morphism $U \rightarrow [U/R]$ (see Diagram (39.1.0.1)). Hence the local properties of $s : R \rightarrow U$ should reflect local properties of the morphism $U \rightarrow [U/R]$. This doesn't work, because $[U/R]$ is not always an algebraic stack, and hence we cannot speak of geometric or algebraic properties of $U \rightarrow [U/R]$. But it turns out that we can make some of it work without even referring to the quotient stack at all.

Here is a first example of such a result. The open $W \subset U'$ found in the lemma is roughly speaking the locus where the morphism $U' \rightarrow [U/R]$ has property \mathcal{P} .

Lemma 39.5.1. *Let S be a scheme. Let (U, R, s, t, c, e, i) be a groupoid over S . Let $g : U' \rightarrow U$ be a morphism of schemes. Denote h the composition*

$$h : U' \times_{g,U,t} R \xrightarrow{\text{pr}_1} R \xrightarrow{s} U.$$

Let $\mathcal{P}, \mathcal{Q}, \mathcal{R}$ be properties of morphisms of schemes. Assume

- (1) $\mathcal{R} \Rightarrow \mathcal{Q}$,
- (2) \mathcal{Q} is preserved under base change and composition,
- (3) for any morphism $f : X \rightarrow Y$ which has \mathcal{Q} there exists a largest open $W(\mathcal{P}, f) \subset X$ such that $f|_{W(\mathcal{P}, f)}$ has \mathcal{P} , and
- (4) for any morphism $f : X \rightarrow Y$ which has \mathcal{Q} , and any morphism $Y' \rightarrow Y$ which has \mathcal{R} we have $Y' \times_Y W(\mathcal{P}, f) = W(\mathcal{P}, f')$, where $f' : X_{Y'} \rightarrow Y'$ is the base change of f .

If s, t have \mathcal{R} and g has \mathcal{Q} , then there exists an open subscheme $W \subset U'$ such that $W \times_{g,U,t} R = W(\mathcal{P}, h)$.

Proof. Note that the following diagram is commutative

$$\begin{array}{ccc} U' \times_{g,U,t} R \times_{t,U,t} R & \xrightarrow{\text{pr}_{12}} & R \times_{t,U,t} R \\ \text{pr}_{01} \downarrow & & \downarrow \text{pr}_0 \\ U' \times_{g,U,t} R & \xrightarrow{\text{pr}_1} & R \\ & & \downarrow \text{pr}_1 \end{array}$$

with both squares cartesian (this uses that the two maps $t \circ \text{pr}_i : R \times_{t,U,t} R \rightarrow U$ are equal). Combining this with the properties of diagram (39.3.0.3) we get a commutative diagram

$$\begin{array}{ccc} U' \times_{g,U,t} R \times_{t,U,t} R & \xrightarrow{c \circ (i,1)} & R \\ \text{pr}_{01} \downarrow & & \downarrow t \\ U' \times_{g,U,t} R & \xrightarrow{h} & U \\ & & \downarrow s \end{array}$$

where both squares are cartesian.

Assume s, t have \mathcal{R} and g has \mathcal{Q} . Then h has \mathcal{Q} as a composition of s (which has \mathcal{R} hence \mathcal{Q}) and a base change of g (which has \mathcal{Q}). Thus $W(\mathcal{P}, h) \subset U' \times_{g,U,t} R$ exists. By our assumptions we have $\text{pr}_{01}^{-1}(W(\mathcal{P}, h)) = \text{pr}_{02}^{-1}(W(\mathcal{P}, h))$ since both are the largest open on which $c \circ (i, 1)$ has \mathcal{P} . Note that the projection $U' \times_{g,U,t} R \rightarrow U'$ has a section, namely $\sigma : U' \rightarrow U' \times_{g,U,t} R$, $u' \mapsto (u', e(g(u')))$. Also via the isomorphism

$$(U' \times_{g,U,t} R) \times_{U'} (U' \times_{g,U,t} R) = U' \times_{g,U,t} R \times_{t,U,t} R$$

the two projections of the left hand side to $U' \times_{g,U,t} R$ agree with the morphisms pr_{01} and pr_{02} on the right hand side. Since $\text{pr}_{01}^{-1}(W(\mathcal{P}, h)) = \text{pr}_{02}^{-1}(W(\mathcal{P}, h))$ we conclude that $W(\mathcal{P}, h)$ is the inverse image of a subset of U , which is necessarily the open set $W = \sigma^{-1}(W(\mathcal{P}, h))$. \square

Remark 39.5.2. Warning: Lemma 39.5.1 should be used with care. For example, it applies to \mathcal{P} = “flat”, \mathcal{Q} = “empty”, and \mathcal{R} = “flat and locally of finite presentation”. But given a morphism of schemes $f : X \rightarrow Y$ the largest open $W \subset X$ such that $f|_W$ is flat is *not* the set of points where f is flat!

Remark 39.5.3. Notwithstanding the warning in Remark 39.5.2 there are some cases where Lemma 39.5.1 can be used without causing too much ambiguity. We give a list. In each case we omit the verification of assumptions (1) and (2) and we give references which imply (3) and (4). Here is the list:

- (1) $\mathcal{Q} = \mathcal{R} =$ “locally of finite type”, and $\mathcal{P} =$ “relative dimension $\leq d$ ”. See Morphisms, Definition 28.30.1 and Morphisms, Lemmas 28.29.4 and 28.29.3.
- (2) $\mathcal{Q} = \mathcal{R} =$ “locally of finite type”, and $\mathcal{P} =$ “locally quasi-finite”. This is the case $d = 0$ of the previous item, see Morphisms, Lemma 28.30.5.
- (3) $\mathcal{Q} = \mathcal{R} =$ “locally of finite type”, and $\mathcal{P} =$ “unramified”. See Morphisms, Lemmas 28.36.3 and 28.36.15.

What is interesting about the cases listed above is that we do not need to assume that s, t are flat to get a conclusion about the locus where the morphism h has property \mathcal{P} . We continue the list:

- (4) $\mathcal{Q} =$ “locally of finite presentation”, $\mathcal{R} =$ “flat and locally of finite presentation”, and $\mathcal{P} =$ “flat”. See More on Morphisms, Theorem 36.12.1 and Lemma 36.12.2.
- (5) $\mathcal{Q} =$ “locally of finite presentation”, $\mathcal{R} =$ “flat and locally of finite presentation”, and $\mathcal{P} =$ “Cohen-Macaulay”. See More on Morphisms, Definition 36.17.1 and More on Morphisms, Lemmas 36.17.4 and 36.17.5.
- (6) $\mathcal{Q} =$ “locally of finite presentation”, $\mathcal{R} =$ “flat and locally of finite presentation”, and $\mathcal{P} =$ “syntomic” use Morphisms, Lemma 28.32.12 (the locus is automatically open).
- (7) $\mathcal{Q} =$ “locally of finite presentation”, $\mathcal{R} =$ “flat and locally of finite presentation”, and $\mathcal{P} =$ “smooth”. See Morphisms, Lemma 28.35.15 (the locus is automatically open).
- (8) $\mathcal{Q} =$ “locally of finite presentation”, $\mathcal{R} =$ “flat and locally of finite presentation”, and $\mathcal{P} =$ “étale”. See Morphisms, Lemma 28.37.17 (the locus is automatically open).

Here is the second result. The R -invariant open $W \subset U$ should be thought of as the inverse image of the largest open of $[U/R]$ over which the morphism $U \rightarrow [U/R]$ has property \mathcal{P} .

Lemma 39.5.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . Let $\tau \in \{\text{Zariski, fppf, étale, smooth, syntomic}\}^1$. Let \mathcal{P} be a property of morphisms of schemes which is τ -local on the target (Descent, Definition 34.18.1). Assume $\{s : R \rightarrow U\}$ and $\{t : R \rightarrow U\}$ are coverings for the τ -topology. Let $W \subset U$ be the maximal open subscheme such that $s|_{s^{-1}(W)} : s^{-1}(W) \rightarrow W$ has property \mathcal{P} . Then W is R -invariant, see Groupoids, Definition 38.17.1.*

Proof. The existence and properties of the open $W \subset U$ are described in Descent, Lemma 34.18.3. In Diagram (39.3.0.2) let $W_1 \subset R$ be the maximal open subscheme over which the morphism $\text{pr}_1 : R \times_{s,U,t} R \rightarrow R$ has property \mathcal{P} . It follows from the aforementioned Descent, Lemma 34.18.3 and the assumption that $\{s : R \rightarrow U\}$ and $\{t : R \rightarrow U\}$ are coverings for the τ -topology that $t^{-1}(W) = W_1 = s^{-1}(W)$ as desired. \square

¹The fact that *fppc* is missing is not a typo.

Lemma 39.5.5. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . Let $G \rightarrow U$ be its stabilizer group scheme. Let $\tau \in \{fppf, \text{étale}, \text{smooth}, \text{syntomic}\}$. Let \mathcal{P} be a property of morphisms which is τ -local on the target. Assume $\{s : R \rightarrow U\}$ and $\{t : R \rightarrow U\}$ are coverings for the τ -topology. Let $W \subset U$ be the maximal open subscheme such that $G_W \rightarrow W$ has property \mathcal{P} . Then W is R -invariant (see Groupoids, Definition 38.17.1).*

Proof. The existence and properties of the open $W \subset U$ are described in Descent, Lemma 34.18.3. The morphism

$$G \times_{U,t} R \longrightarrow R \times_{s,U} G, \quad (g, r) \longmapsto (r, r^{-1} \circ g \circ r)$$

is an isomorphism over R (where \circ denotes composition in the groupoid). Hence $s^{-1}(W) = t^{-1}(W)$ by the properties of W proved in the aforementioned Descent, Lemma 34.18.3. \square

39.6. Comparing fibres

Let (U, R, s, t, c, e, i) be a groupoid scheme over S . Diagram (39.3.0.2) gives us a way to compare the fibres of the map $s : R \rightarrow U$ in a groupoid. For a point $u \in U$ we will denote $F_u = s^{-1}(u)$ the scheme theoretic fibre of $s : R \rightarrow U$ over u . For example the diagram implies that if $u, u' \in U$ are points such that $s(r) = u$ and $t(r) = u'$, then $(F_u)_{\kappa(r)} \cong (F_{u'})_{\kappa(r)}$. This is a special case of the more general and more precise Lemma 39.6.1 below. To see this take $r' = i(r)$.

A pair (X, x) consisting of a scheme X and a point $x \in X$ is sometimes called the *germ of X at x* . A *morphism of germs* $f : (X, x) \rightarrow (S, s)$ is a morphism $f : U \rightarrow S$ defined on an open neighbourhood of x with $f(x) = s$. Two such f, f' are said to give the same morphism of germs if and only if f and f' agree in some open neighbourhood of x . Let $\tau \in \{\text{Zariski}, \text{étale}, \text{smooth}, \text{syntomic}, \text{fppf}\}$. We temporarily introduce the following concept: We say that two morphisms of germs $f : (X, x) \rightarrow (S, s)$ and $f' : (X', x') \rightarrow (S', s')$ are *isomorphic locally on the base in the τ -topology*, if there exists a pointed scheme (S'', s'') and morphisms of germs $g : (S'', s'') \rightarrow (S, s)$, and $g' : (S'', s'') \rightarrow (S', s')$ such that

- (1) g and g' are an open immersion (resp. étale, smooth, syntomic, flat and locally of finite presentation) at s'' ,
- (2) there exists an isomorphism

$$(S'' \times_{g,S,f} X, \tilde{x}) \cong (S'' \times_{g',S',f'} X', \tilde{x}')$$

of germs over the germ (S'', s'') for some choice of points \tilde{x} and \tilde{x}' lying over (s'', x) and (s'', x') .

Finally, we simply say that the maps of germs $f : (X, x) \rightarrow (S, s)$ and $f' : (X', x') \rightarrow (S', s')$ are *flat locally on the base isomorphic* if there exist S'', s'', g, g' as above but with (1) replaced by the condition that g and g' are flat at s'' (this is much weaker than any of the τ conditions above as a flat morphism need not be open).

Lemma 39.6.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . Let $r, r' \in R$ with $t(r) = t(r')$ in U . Set $u = s(r)$, $u' = s(r')$. Denote $F_u = s^{-1}(u)$ and $F_{u'} = s^{-1}(u')$ the scheme theoretic fibres.*

- (1) *There exists a common field extension $\kappa(u) \subset k$, $\kappa(u') \subset k$ and an isomorphism $(F_u)_k \cong (F_{u'})_k$.*

- (2) We may choose the isomorphism of (1) such that a point lying over r maps to a point lying over r' .
- (3) If the morphisms s, t are flat then the morphisms of germs $s : (R, r) \rightarrow (U, u)$ and $s : (R, r') \rightarrow (U, u')$ are flat locally on the base isomorphic.
- (4) If the morphisms s, t are étale (resp. smooth, syntomic, or flat and locally of finite presentation) then the morphisms of germs $s : (R, r) \rightarrow (U, u)$ and $s : (R, r') \rightarrow (U, u')$ are locally on the base isomorphic in the étale (resp. smooth, syntomic, or fppf) topology.

Proof. We repeatedly use the properties and the existence of diagram (39.3.0.2). By the properties of the diagram (and Schemes, Lemma 25.17.5) there exists a point ξ of $R \times_{s,U,t} R$ with $\text{pr}_0(\xi) = r$ and $c(\xi) = r'$. Let $\tilde{r} = \text{pr}_1(\xi) \in R$.

Proof of (1). Set $k = \kappa(\tilde{r})$. Since $t(\tilde{r}) = u$ and $s(\tilde{r}) = u'$ we see that k is a common extension of both $\kappa(u)$ and $\kappa(u')$ and in fact that both $(F_u)_k$ and $(F_{u'})_k$ are isomorphic to the fibre of $\text{pr}_1 : R \times_{s,U,t} R \rightarrow R$ over \tilde{r} . Hence (1) is proved.

Part (2) follows since the point ξ maps to r , resp. r' .

Part (3) is clear from the above (using the point ξ for \tilde{u} and \tilde{u}') and the definitions.

If s and t are flat and of finite presentation, then they are open morphisms (Morphisms, Lemma 28.26.9). Hence the image of some affine open neighbourhood V'' of \tilde{r} will cover an open neighbourhood V of u , resp. V' of u' . These can be used to show that properties (1) and (2) of the definition of “locally on the base isomorphic in the τ -topology”. \square

39.7. Cohen-Macaulay presentations

Given any groupoid (U, R, s, t, c) with s, t flat and locally of finite presentation there exists an “equivalent” groupoid (U', R', s', t', c') such that s' and t' are Cohen-Macaulay morphisms (and locally of finite presentation). See More on Morphisms, Section 36.17 for more information on Cohen-Macaulay morphisms. Here “equivalent” can be taken to mean that the quotient stacks $[U/R]$ and $[U'/R']$ are equivalent stacks, see Groupoids in Spaces, Section 60.19 and Section 60.24.

Lemma 39.7.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid over S . Assume s and t are flat and locally of finite presentation. Then there exists an open $U' \subset U$ such that*

- (1) $t^{-1}(U') \subset R$ is the largest open subscheme of R on which the morphism s is Cohen-Macaulay,
- (2) $s^{-1}(U') \subset R$ is the largest open subscheme of R on which the morphism t is Cohen-Macaulay,
- (3) the morphism $t|_{s^{-1}(U')} : s^{-1}(U') \rightarrow U$ is surjective,
- (4) the morphism $s|_{t^{-1}(U')} : t^{-1}(U') \rightarrow U$ is surjective, and
- (5) the restriction $R' = s^{-1}(U') \cap t^{-1}(U')$ of R to U' defines a groupoid (U', R', s', t', c') which has the property that the morphisms s' and t' are Cohen-Macaulay and locally of finite presentation.

Proof. Apply Lemma 39.5.1 with $g = \text{id}$ and $\mathcal{Q} =$ “locally of finite presentation”, $\mathcal{R} =$ “flat and locally of finite presentation”, and $\mathcal{P} =$ “Cohen-Macaulay”, see Remark 39.5.3. This gives us an open $U' \subset U$ such that Let $t^{-1}(U') \subset R$ is the largest open subscheme of R on which the morphism s is Cohen-Macaulay. This proves

(1). Let $i : R \rightarrow R$ be the inverse of the groupoid. Since i is an isomorphism, and $s \circ i = t$ and $t \circ i = s$ we see that $s^{-1}(U')$ is also the largest open of R on which t is Cohen-Macaulay. This proves (2). By More on Morphisms, Lemma 36.17.5 the open subset $t^{-1}(U')$ is dense in every fibre of $s : R \rightarrow U$. This proves (3). Same argument for (4). Part (5) is a formal consequence of (1) and (2) and the discussion of restrictions in Groupoids, Section 38.16. \square

39.8. Restricting groupoids

In this section we collect a bunch of lemmas on properties of groupoids which are inherited by restrictions. Most of these lemmas can be proved by contemplating the defining diagram

$$(39.8.0.1) \quad \begin{array}{ccccc} & & & & s' \\ & & & & \curvearrowright \\ & & R' & \xrightarrow{\quad} & R \times_{s,U} U' & \xrightarrow{\quad} & U' \\ & & \downarrow & & \downarrow & & \downarrow g \\ t' & \curvearrowleft & U' \times_{U,t} R & \xrightarrow{\quad} & R & \xrightarrow{s} & U \\ & & \downarrow & & \downarrow t & & \\ & & U' & \xrightarrow{g} & U & & \end{array}$$

of a restriction. See Groupoids, Lemma 38.16.1.

Lemma 39.8.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ be a morphism of schemes. Let (U', R', s', t', c') be the restriction of (U, R, s, t, c) via g .*

- (1) *If s, t are locally of finite type and g is locally of finite type, then s', t' are locally of finite type.*
- (2) *If s, t are locally of finite presentation and g is locally of finite presentation, then s', t' are locally of finite presentation.*
- (3) *If s, t are flat and g is flat, then s', t' are flat.*
- (4) *Add more here.*

Proof. The property of being locally of finite type is stable under composition and arbitrary base change, see Morphisms, Lemmas 28.16.3 and 28.16.4. Hence (1) is clear from Diagram (39.8.0.1). For the other cases, see Morphisms, Lemmas 28.22.3, 28.22.4, 28.26.5, and 28.26.7. \square

The following lemma could have been used to prove the results of the preceding lemma in a more uniform way.

Lemma 39.8.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ be a morphism of schemes. Let (U', R', s', t', c') be the restriction of (U, R, s, t, c) via g , and let $h = s \circ pr_1 : U' \times_{g,U,t} R \rightarrow U$. If \mathcal{P} is a property of morphisms of schemes such that*

- (1) *h has property \mathcal{P} , and*
- (2) *\mathcal{P} is preserved under base change,*

then s', t' have property \mathcal{P} .

Proof. This is clear as s' is the base change of h by Diagram (39.8.0.1) and t' is isomorphic to s' as a morphism of schemes. \square

Lemma 39.8.3. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ and $g' : U'' \rightarrow U'$ be morphisms of schemes. Set $g'' = g \circ g'$. Let (U', R', s', t', c') be the restriction of R to U' . Let $h = s \circ pr_1 : U' \times_{g, U, t} R \rightarrow U$, let $h' = s' \circ pr_1 : U'' \times_{g', U', t} R' \rightarrow U'$, and let $h'' = s \circ pr_1 : U'' \times_{g'', U, t} R \rightarrow U$. The following diagram is commutative*

$$\begin{array}{ccccc}
 U'' \times_{g', U', t} R' & \longleftarrow & (U' \times_{g, U, t} R) \times_U (U'' \times_{g'', U, t} R) & \longrightarrow & U'' \times_{g'', U, t} R \\
 \downarrow h' & & \downarrow & & \downarrow h'' \\
 U' & \xleftarrow{pr_0} & U' \times_{g, U, t} R & \xrightarrow{h} & U
 \end{array}$$

with both squares cartesian where the left upper horizontal arrow is given by the rule

$$\begin{array}{ccc}
 (U' \times_{g, U, t} R) \times_U (U'' \times_{g'', U, t} R) & \longrightarrow & U'' \times_{g', U', t} R' \\
 ((u', r_0), (u'', r_1)) & \longmapsto & (u'', (c(r_1, i(r_0)), (g'(u''), u')))
 \end{array}$$

with notation as explained in the proof.

Proof. We work this out by exploiting the functorial point of view and reducing the lemma to a statement on arrows in restrictions of a groupoid category. In the last formula of the lemma the notation $((u', r_0), (u'', r_1))$ indicates a T -valued point of $(U' \times_{g, U, t} R) \times_U (U'' \times_{g'', U, t} R)$. This means that u', u'', r_0, r_1 are T -valued points of U', U'', R, R and that $g(u') = t(r_0)$, $g(g'(u'')) = g''(u'') = t(r_1)$, and $s(r_0) = s(r_1)$. It would be more correct here to write $g \circ u' = t \circ r_0$ and so on but this makes the notation even more unreadable. If we think of r_1 and r_0 as arrows in a groupoid category then we can represent this by the picture

$$t(r_0) = g(u') \xleftarrow{r_0} s(r_0) = s(r_1) \xrightarrow{r_1} t(r_1) = g(g'(u''))$$

This diagram in particular demonstrates that the composition $c(r_1, i(r_0))$ makes sense. Recall that

$$R' = R \times_{(t, s), U \times_S U, g \times g} U' \times_S U'$$

hence a T -valued point of R' looks like $(r, (u'_0, u'_1))$ with $t(r) = g(u'_0)$ and $s(r) = g(u'_1)$. In particular given $((u', r_0), (u'', r_1))$ as above we get the T -valued point $(c(r_1, i(r_0)), (g'(u''), u'))$ of R' because we have $t(c(r_1, i(r_0))) = t(r_1) = g(g'(u''))$ and $s(c(r_1, i(r_0))) = s(i(r_0)) = t(r_0) = g(u')$. We leave it to the reader to show that the left square commutes with this definition.

To show that the left square is cartesian, suppose we are given (v'', p') and (v', p) which are T -valued points of $U'' \times_{g', U', t} R'$ and $U' \times_{g, U, t} R$ with $v' = s'(p')$. This also means that $g'(v'') = t'(p')$ and $g(v') = t(p)$. By the discussion above we know that we can write $p' = (r, (u'_0, u'_1))$ with $t(r) = g(u'_0)$ and $s(r) = g(u'_1)$. Using this notation we see that $v' = s'(p') = u'_1$ and $g'(v'') = t'(p') = u'_0$. Here is a picture

$$s(p) \xrightarrow{p} g(v') = g(u'_1) \xrightarrow{r} g(u'_0) = g(g'(v''))$$

What we have to show is that there exists a unique T -valued point $((u', r_0), (u'', r_1))$ as above such that $v' = u'$, $p = r_0$, $v'' = u''$ and $p' = (c(r_1, i(r_0)), (g'(u''), u'))$. Comparing the two diagrams above it is clear that we have no choice but to take

$$((u', r_0), (u'', r_1)) = ((v', p), (v'', c(r, p)))$$

Some details omitted. □

Lemma 39.8.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ and $g' : U'' \rightarrow U'$ be morphisms of schemes. Set $g'' = g \circ g'$. Let (U', R', s', t', c') be the restriction of R to U' . Let $h = s \circ \text{pr}_1 : U' \times_{g, U, t} R \rightarrow U$, let $h' = s' \circ \text{pr}_1 : U'' \times_{g', U', t} R \rightarrow U'$, and let $h'' = s \circ \text{pr}_1 : U'' \times_{g'', U, t} R \rightarrow U$. Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf, fpqc}\}$. Let \mathcal{P} be a property of morphisms of schemes which is preserved under base change, and which is local on the target for the τ -topology. If*

- (1) $h(U' \times_U R)$ is open in U ,
- (2) $\{h : U' \times_U R \rightarrow h(U' \times_U R)\}$ is a τ -covering,
- (3) h' has property \mathcal{P} ,

then h'' has property \mathcal{P} . Conversely, if

- (a) $\{t : R \rightarrow U\}$ is a τ -covering,
- (d) h'' has property \mathcal{P} ,

then h' has property \mathcal{P} .

Proof. This follows formally from the properties of the diagram of Lemma 39.8.3. In the first case, note that the image of the morphism h'' is contained in the image of h , as $g'' = g \circ g'$. Hence we may replace the U in the lower right corner of the diagram by $h(U' \times_U R)$. This explains the significance of conditions (1) and (2) in the lemma. In the second case, note that $\{\text{pr}_0 : U' \times_{g, U, t} R \rightarrow U'\}$ is a τ -covering as a base change of τ and condition (a). \square

39.9. Properties of groupoids on fields

A “groupoid on a field” indicates a groupoid scheme (U, R, s, t, c) where U is the spectrum of a field. It does **not** mean that (U, R, s, t, c) is defined over a field, more precisely, it does **not** mean that the morphisms $s, t : R \rightarrow U$ are equal. Given any field k , an abstract group G and a group homomorphism $\varphi : G \rightarrow \text{Aut}(k)$ we obtain a groupoid scheme (U, R, s, t, c) over \mathbf{Z} by setting

$$\begin{aligned} U &= \text{Spec}(k) \\ R &= \coprod_{g \in G} \text{Spec}(k) \\ s &= \coprod_{g \in G} \text{Spec}(\text{id}_k) \\ t &= \coprod_{g \in G} \text{Spec}(\varphi(g)) \\ c &= \text{composition in } G \end{aligned}$$

This example still is a groupoid scheme over $\text{Spec}(k^G)$. Hence, if G is finite, then $U = \text{Spec}(k)$ is finite over $\text{Spec}(k^G)$. In some sense our goal in this section is to show that suitable finiteness conditions on s, t force any groupoid on a field to be defined over a finite index subfield $k' \subset k$.

If k is a field and (G, m) is a group scheme over k with structure morphism $p : G \rightarrow \text{Spec}(k)$, then $(\text{Spec}(k), G, p, p, m)$ is an example of a groupoid on a field (and in this case of course the whole structure is defined over a field). Hence this section can be viewed as the analogue of Groupoids, Section 38.7.

Lemma 39.9.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . If U is the spectrum of a field, then the composition morphism $c : R \times_{s, U, t} R \rightarrow R$ is open.*

Proof. The composition is isomorphic to the projection map $\text{pr}_1 : R \times_{t,U,t} R \rightarrow R$ by Diagram (39.3.0.3). The projection is open by Morphisms, Lemma 28.24.4. \square

Lemma 39.9.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . If U is the spectrum of a field, then R is a separated scheme.*

Proof. By Groupoids, Lemma 38.7.2 the stabilizer group scheme $G \rightarrow U$ is separated. By Groupoids, Lemma 38.20.2 the morphism $j = (t, s) : R \rightarrow U \times_S U$ is separated. As U is the spectrum of a field the scheme $U \times_S U$ is affine (by the construction of fibre products in Schemes, Section 25.17). Hence R is a separated scheme, see Schemes, Lemma 25.21.13. \square

Lemma 39.9.3. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. For any points $r, r' \in R$ there exists a field extension $k \subset k'$ and points $r_1, r_2 \in R \times_{s, \text{Spec}(k)} \text{Spec}(k')$ and a diagram*

$$R \xleftarrow{\text{pr}_0} R \times_{s, \text{Spec}(k)} \text{Spec}(k') \xrightarrow{\varphi} R \times_{s, \text{Spec}(k)} \text{Spec}(k') \xrightarrow{\text{pr}_0} R$$

such that φ is an isomorphism of schemes over $\text{Spec}(k')$, we have $\varphi(r_1) = r_2$, $\text{pr}_0(r_1) = r$, and $\text{pr}_0(r_2) = r'$.

Proof. This is a special case of Lemma 39.6.1 parts (1) and (2). \square

Lemma 39.9.4. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. Let $k \subset k'$ be a field extension, $U' = \text{Spec}(k')$ and let (U', R', s', t', c') be the restriction of (U, R, s, t, c) via $U' \rightarrow U$. In the defining diagram*

all the morphisms are surjective, flat, and universally open. The dotted arrow $R' \rightarrow R$ is in addition affine.

Proof. The morphism $U' \rightarrow U$ equals $\text{Spec}(k') \rightarrow \text{Spec}(k)$, hence is affine, surjective and flat. The morphisms $s, t : R \rightarrow U$ and the morphism $U' \rightarrow U$ are universally open by Morphisms, Lemma 28.24.4. Since R is not empty and U is the spectrum of a field the morphisms $s, t : R \rightarrow U$ are surjective and flat. Then you conclude by using Morphisms, Lemmas 28.11.4, 28.11.2, 28.24.3, 28.13.8, 28.13.7, 28.26.7, and 28.26.5. \square

Lemma 39.9.5. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. For any point $r \in R$ there exist*

- (1) a field extension $k \subset k'$ with k' algebraically closed,
- (2) a point $r' \in R'$ where (U', R', s', t', c') is the restriction of (U, R, s, t, c) via $\text{Spec}(k') \rightarrow \text{Spec}(k)$

such that

- (1) the point r' maps to r under the morphism $R' \rightarrow R$, and
- (2) the maps $s', t' : R' \rightarrow \text{Spec}(k')$ induce isomorphisms $k' \rightarrow \kappa(r')$.

Proof. Translating the geometric statement into a statement on fields, this means that we can find a diagram

where $i : k \rightarrow k'$ is the embedding of k into k' , the maps $s, t : k \rightarrow \kappa(r)$ are induced by $s, t : R \rightarrow U$, and the map $\tau : k' \rightarrow k'$ is an automorphism. To produce such a diagram we may proceed in the following way:

- (1) Pick $i : k \rightarrow k'$ a field map with k' algebraically closed of very large transcendence degree over k .
- (2) Pick an embedding $\sigma : \kappa(r) \rightarrow k'$ such that $\sigma \circ s = i$. Such a σ exists because we can just choose a transcendence basis $\{x_\alpha\}_{\alpha \in A}$ of $\kappa(r)$ over k and find $y_\alpha \in k', \alpha \in A$ which are algebraically independent over $i(k)$, and map $s(k)(\{x_\alpha\})$ into k' by the rules $s(\lambda) \mapsto i(\lambda)$ for $\lambda \in k$ and $x_\alpha \mapsto y_\alpha$ for $\alpha \in A$. Then extend to $\tau : \kappa(\alpha) \rightarrow k'$ using that k' is algebraically closed.
- (3) Pick an automorphism $\tau : k' \rightarrow k'$ such that $\tau \circ i = \sigma \circ t$. To do this pick a transcendence basis $\{x_\alpha\}_{\alpha \in A}$ of k over its prime field. On the one hand, extend $\{i(x_\alpha)\}$ to a transcendence basis of k' by adding $\{y_\beta\}_{\beta \in B}$ and extend $\{\sigma(t(x_\alpha))\}$ to a transcendence basis of k' by adding $\{z_\gamma\}_{\gamma \in C}$. As k' is algebraically closed we can extend the isomorphism $\sigma \circ t \circ i^{-1} : i(k) \rightarrow \sigma(t(k))$ to an isomorphism $\tau' : \overline{i(k)} \rightarrow \overline{\sigma(t(k))}$ of their algebraic closures in k' . As k' has large transcendence degree we see that the sets B and C have the same cardinality. Thus we can use a bijection $B \rightarrow C$ to extend τ' to an isomorphism

$$\overline{i(k)}(\{y_\beta\}) \longrightarrow \overline{\sigma(t(k))}(\{z_\gamma\})$$

and then since k' is the algebraic closure of both sides we see that this extends to an automorphism $\tau : k' \rightarrow k'$ as desired.

This proves the lemma. □

Lemma 39.9.6. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. If $r \in R$ is a point such that s, t induce isomorphisms $k \rightarrow \kappa(r)$, then the map*

$$R \longrightarrow R, \quad x \longmapsto c(r, x)$$

(see proof for precise notation) is an automorphism $R \rightarrow R$ which maps e to r .

Proof. This is completely obvious if you think about groupoids in a functorial way. But we will also spell it out completely. Denote $a : U \rightarrow R$ the morphism with image r such that $s \circ a = \text{id}_U$ which exists by the hypothesis that $s : k \rightarrow \kappa(r)$ is an

isomorphism. Similarly, denote $b : U \rightarrow R$ the morphism with image r such that $t \circ b = \text{id}_U$. Note that $b = a \circ (t \circ a)^{-1}$, in particular $a \circ s \circ b = b$.

Consider the morphism $\Psi : R \rightarrow R$ given on T -valued points by

$$(f : T \rightarrow R) \mapsto (c(a \circ t \circ f, f) : T \rightarrow R)$$

To see this is defined we have to check that $s \circ a \circ t \circ f = t \circ f$ which is obvious as $s \circ a = 1$. Note that $\Phi(e) = a$, so that in order to prove the lemma it suffices to show that Φ is an automorphism of R . Let $\Phi : R \rightarrow R$ be the morphism given on T -valued points by

$$(g : T \rightarrow R) \mapsto (c(i \circ b \circ t \circ g, g) : T \rightarrow R).$$

This is defined because $s \circ i \circ b \circ t \circ g = t \circ b \circ t \circ g = t \circ g$. We claim that Φ and Ψ are inverse to each other. To see this we compute

$$\begin{aligned} & c(a \circ t \circ c(i \circ b \circ t \circ g, g), c(i \circ b \circ t \circ g, g)) \\ &= c(a \circ t \circ i \circ b \circ t \circ g, c(i \circ b \circ t \circ g, g)) \\ &= c(a \circ s \circ b \circ t \circ g, c(i \circ b \circ t \circ g, g)) \\ &= c(b \circ t \circ g, c(i \circ b \circ t \circ g, g)) \\ &= c(c(b \circ t \circ g, i \circ b \circ t \circ g), g) \\ &= c(e, g) \\ &= g \end{aligned}$$

where we have used the relation $a \circ s \circ b = b$ shown above. In the other direction we have

$$\begin{aligned} & c(i \circ b \circ t \circ c(a \circ t \circ f, f), c(a \circ t \circ f, f)) \\ &= c(i \circ b \circ t \circ a \circ t \circ f, c(a \circ t \circ f, f)) \\ &= c(i \circ a \circ (t \circ a)^{-1} \circ t \circ a \circ t \circ f, c(a \circ t \circ f, f)) \\ &= c(i \circ a \circ t \circ f, c(a \circ t \circ f, f)) \\ &= c(c(i \circ a \circ t \circ f, a \circ t \circ f), f) \\ &= c(e, f) \\ &= f \end{aligned}$$

The lemma is proved. \square

Lemma 39.9.7. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. By abuse of notation denote $e \in R$ the image of the identity morphism $e : U \rightarrow R$. Then*

- (1) every local ring $\mathcal{O}_{R,r}$ of R has a unique minimal prime ideal,
- (2) there is exactly one irreducible component Z of R passing through e , and
- (3) Z is geometrically irreducible over k via either s or t .

Proof. Let $r \in R$ be a point. In this proof we will use the correspondence between irreducible components of R passing through a point r and minimal primes of the local ring $\mathcal{O}_{R,r}$ without further mention. Choose $k \subset k'$ and $r' \in R'$ as in Lemma 39.9.5. Note that $\mathcal{O}_{R,r} \rightarrow \mathcal{O}_{R',r'}$ is faithfully flat and local, see Lemma 39.9.4. Hence the result for $r' \in R'$ implies the result for $r \in R$. In other words we may assume that $s, t : k \rightarrow \kappa(r)$ are isomorphisms. By Lemma 39.9.6 there exists an

automorphism moving e to r . Hence we may assume $r = e$, i.e., part (1) follows from part (2).

We first prove (2) in case k is separably algebraically closed. Namely, let $X, Y \subset R$ be irreducible components passing through e . Then by Varieties, Lemma 32.6.4 and 32.6.3 the scheme $X \times_{s,U,t} Y$ is irreducible as well. Hence $c(X \times_{s,U,t} Y) \subset R$ is an irreducible subset. We claim it contains both X and Y (as subsets of R). Namely, let T be the spectrum of a field. If $x : T \rightarrow X$ is a T -valued point of X , then $c(x, e \circ s \circ x) = x$ and $e \circ s \circ x$ factors through Y as $e \in Y$. Similarly for points of Y . This clearly implies that $X = Y$, i.e., there is a unique irreducible component of R passing through e .

Proof of (2) and (3) in general. Let $k \subset k'$ be a separable algebraic closure, and let (U', R', s', t', c') be the restriction of (U, R, s, t, c) via $\text{Spec}(k') \rightarrow \text{Spec}(k)$. By the previous paragraph there is exactly one irreducible component Z' of R' passing through e' . Denote $e'' \in R \times_{s,U} U'$ the base change of e . As $R' \rightarrow R \times_{s,U} U'$ is faithfully flat, see Lemma 39.9.4, and $e' \mapsto e''$ we see that there is exactly one irreducible component Z'' of $R \times_{s,k} k'$ passing through e'' . This implies, as $R \times_k k' \rightarrow R$ is faithfully flat, that there is exactly one irreducible component Z of R passing through e . This proves (2).

To prove (3) let $Z''' \subset R \times_k k'$ be an arbitrary irreducible component of $Z \times_k k'$. By Varieties, Lemma 32.6.12 we see that $Z''' = \sigma(Z'')$ for some $\sigma \in \text{Gal}(k'/k)$. Since $\sigma(e'') = e''$ we see that $e'' \in Z'''$ and hence $Z''' = Z''$. This means that Z is geometrically irreducible over $\text{Spec}(k)$ via the morphism s . The same argument implies that Z is geometrically irreducible over $\text{Spec}(k)$ via the morphism t . \square

Lemma 39.9.8. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. Assume s, t are locally of finite type. Then*

- (1) R is equidimensional,
- (2) $\dim(R) = \dim_r(R)$ for all $r \in R$,
- (3) for any $r \in R$ we have $\text{trdeg}_{s(k)}(\kappa(r)) = \text{trdeg}_{t(k)}(\kappa(r))$, and
- (4) for any closed point $r \in R$ we have $\dim(R) = \dim(\mathcal{O}_{R,r})$.

Proof. Let $r, r' \in R$. Then $\dim_r(R) = \dim_{r'}(R)$ by Lemma 39.9.3 and Morphisms, Lemma 28.29.3. By Morphisms, Lemma 28.29.1 we have

$$\dim_r(R) = \dim(\mathcal{O}_{R,r}) + \text{trdeg}_{s(k)}(\kappa(r)) = \dim(\mathcal{O}_{R,r}) + \text{trdeg}_{t(k)}(\kappa(r)).$$

On the other hand, the dimension of R (or any open subset of R) is the supremum of the dimensions of the local rings of R , see Properties, Lemma 27.11.4. Clearly this is maximal for closed points r in which case $\text{trdeg}_k(\kappa(r)) = 0$ (by the Hilbert Nullstellensatz, see Morphisms, Section 28.17). Hence the lemma follows. \square

Lemma 39.9.9. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume $U = \text{Spec}(k)$ with k a field. Assume s, t are locally of finite type. Then $\dim(R) = \dim(G)$ where G is the stabilizer group scheme of R .*

Proof. Let $Z \subset R$ be the irreducible component passing through e (see Lemma 39.9.7) thought of as an integral closed subscheme of R . Let k'_s , resp. k'_t be the integral closure of $s(k)$, resp. $t(k)$ in $\Gamma(Z, \mathcal{O}_Z)$. Recall that k'_s and k'_t are fields, see

Varieties, Lemma 32.17.4. By Varieties, Proposition 32.18.1 we have $k'_s = k'_t$ as subrings of $\Gamma(Z, \mathcal{O}_Z)$. As e factors through Z we obtain a commutative diagram

This on the one hand shows that $k'_s = s(k)$, $k'_t = t(k)$, so $s(k) = t(k)$, which combined with the diagram above implies that $s = t!$ In other words, we conclude that Z is a closed subscheme of $G = R \times_{(t,s), U \times_s U, \Delta} U$. The lemma follows as both G and R are equidimensional, see Lemma 39.9.8 and Groupoids, Lemma 38.7.5. \square

Remark 39.9.10. Warning: Lemma 39.9.9 is wrong without the condition that s and t are locally of finite type. An easy example is to start with the action

$$\mathbf{G}_{m, \mathbf{Q}} \times_{\mathbf{Q}} \mathbf{A}_{\mathbf{Q}}^1 \rightarrow \mathbf{A}_{\mathbf{Q}}^1$$

and restrict the corresponding groupoid scheme to the generic point of $\mathbf{A}_{\mathbf{Q}}^1$. In other words restrict via the morphism $\text{Spec}(\mathbf{Q}(x)) \rightarrow \text{Spec}(\mathbf{Q}[x]) = \mathbf{A}_{\mathbf{Q}}^1$. Then you get a groupoid scheme (U, R, s, t, c) with $U = \text{Spec}(\mathbf{Q}(x))$ and

$$R = \text{Spec} \left(\mathbf{Q}(x)[y] \left[\frac{1}{P(xy)}, P \in \mathbf{Q}[T], P \neq 0 \right] \right)$$

In this case $\dim(R) = 1$ and $\dim(G) = 0$.

Lemma 39.9.11. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume*

- (1) $U = \text{Spec}(k)$ with k a field,
- (2) s, t are locally of finite type, and
- (3) the characteristic of k is zero.

Then $s, t : R \rightarrow U$ are smooth.

Proof. By Lemma 39.4.1 the sheaf of differentials of $R \rightarrow U$ is free. Hence smoothness follows from Varieties, Lemma 32.15.1. \square

Lemma 39.9.12. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume*

- (1) $U = \text{Spec}(k)$ with k a field,
- (2) s, t are locally of finite type,
- (3) R is reduced, and
- (4) k is perfect.

Then $s, t : R \rightarrow U$ are smooth.

Proof. By Lemma 39.4.1 the sheaf $\Omega_{R/U}$ is free. Hence the lemma follows from Varieties, Lemma 32.15.2. \square

39.10. Morphisms of groupoids on fields

This section studies morphisms between groupoids on fields. This is slightly more general, but very akin to, studying morphisms of groupschemes over a field.

Situation 39.10.1. Let S be a scheme. Let $U = \text{Spec}(k)$ be a scheme over S with k a field. Let $(U, R_1, s_1, t_1, c_1), (U, R_2, s_2, t_2, c_2)$ be groupoid schemes over S with identical first component. Let $a : R_1 \rightarrow R_2$ be a morphism such that (id_U, a) defines a morphism of groupoid schemes over S , see Groupoids, Definition 38.11.1. In particular, the following diagrams commute

The following lemma is a generalization of Groupoids, Lemma 38.7.11.

Lemma 39.10.2. *Notation and assumptions as in Situation 39.10.1. If $a(R_1)$ is open in R_2 , then $a(R_1)$ is closed in R_2 .*

Proof. Let $r_2 \in R_2$ be a point in the closure of $a(R_1)$. We want to show $r_2 \in a(R_1)$. Pick $k \subset k'$ and $r'_2 \in R'_2$ adapted to (U, R_2, s_2, t_2, c_2) and r_2 as in Lemma 39.9.5. Let R'_i be the restriction of R_i via the morphism $U' = \text{Spec}(k') \rightarrow U = \text{Spec}(k)$. Let $a' : R'_1 \rightarrow R'_2$ be the base change of a . The diagram

is a fibre square. Hence the image of a' is the inverse image of the image of a via the morphism $p_2 : R'_2 \rightarrow R_2$. By Lemma 39.9.4 the map p_2 is surjective and open. Hence by Topology, Lemma 5.5.4 we see that r'_2 is in the closure of $a'(R'_1)$. This means that we may assume that $r_2 \in R_2$ has the property that the maps $k \rightarrow \kappa(r_2)$ induced by s_2 and t_2 are isomorphisms.

In this case we can use Lemma 39.9.6. This lemma implies $c(r_2, a(R_1))$ is an open neighbourhood of r_2 . Hence $a(R_1) \cap c(r_2, a(R_1)) \neq \emptyset$ as we assumed that r_2 was a point of the closure of $a(R_1)$. Using the inverse of R_2 and R_1 we see this means $c_2(a(R_1), a(R_1))$ contains r_2 . As $c_2(a(R_1), a(R_1)) \subset a(c_1(R_1, R_1)) = a(R_1)$ we conclude $r_2 \in a(R_1)$ as desired. \square

Lemma 39.10.3. *Notation and assumptions as in Situation 39.10.1. Let $Z \subset R_2$ be the reduced closed subscheme (see Schemes, Definition 25.12.5) whose underlying topological space is the closure of the image of $a : R_1 \rightarrow R_2$. Then $c_2(Z \times_{s_2, U, t_2} Z) \subset Z$ set theoretically.*

Proof. Consider the commutative diagram

$$\begin{array}{ccc} R_1 \times_{s_1, U, t_1} R_1 & \longrightarrow & R_1 \\ \downarrow & & \downarrow \\ R_2 \times_{s_2, U, t_2} R_2 & \longrightarrow & R_2 \end{array}$$

By Varieties, Lemma 32.14.2 the closure of the image of the left vertical arrow is (set theoretically) $Z \times_{s_2, U, t_2} Z$. Hence the result follows. \square

Lemma 39.10.4. *Notation and assumptions as in Situation 39.10.1. Assume that k is perfect. Let $Z \subset R_2$ be the reduced closed subscheme (see Schemes, Definition 25.12.5) whose underlying topological space is the closure of the image of $a : R_1 \rightarrow R_2$. Then*

$$(U, Z, s_2|_Z, t_2|_Z, c_2|_Z)$$

is a groupoid scheme over S .

Proof. We first explain why the statement makes sense. Since U is the spectrum of a perfect field k , the scheme Z is geometrically reduced over k (via either projection), see Varieties, Lemma 32.4.3. Hence the scheme $Z \times_{s_2, U, t_2} Z \subset Z$ is reduced, see Varieties, Lemma 32.4.7. Hence by Lemma 39.10.3 we see that c induces a morphism $Z \times_{s_2, U, t_2} Z \rightarrow Z$. Finally, it is clear that e_2 factors through Z and that the map $i_2 : R_2 \rightarrow R_2$ preserves Z . Since the morphisms of the septuple $(U, R_2, s_2, t_2, c_2, e_2, i_2)$ satisfies the axioms of a groupoid, it follows that after restricting to Z they satisfy the axioms. \square

Lemma 39.10.5. *Notation and assumptions as in Situation 39.10.1. If the image $a(R_1)$ is a locally closed subset of R_2 then it is a closed subset.*

Proof. Let $k \subset k'$ be a perfect closure of the field k . Let R'_i be the restriction of R_i via the morphism $U' = \text{Spec}(k') \rightarrow \text{Spec}(k)$. Note that the morphisms $R'_i \rightarrow R_i$ are universal homeomorphisms as compositions of base changes of the universal homeomorphism $U' \rightarrow U$ (see diagram in statement of Lemma 39.9.4). Hence it suffices to prove that $a'(R'_1)$ is closed in R'_2 . In other words, we may assume that k is perfect.

If k is perfect, then the closure of the image is a groupoid scheme $Z \subset R_2$, by Lemma 39.10.4. By the same lemma applied to $\text{id}_{R_1} : R_1 \rightarrow R_1$ we see that $(R_2)_{\text{red}}$ is a groupoid scheme. Thus we may apply Lemma 39.10.2 to the morphism $a|_{(R_2)_{\text{red}}} : (R_2)_{\text{red}} \rightarrow Z$ to conclude that Z equals the image of a . \square

Lemma 39.10.6. *Notation and assumptions as in Situation 39.10.1. Assume that $a : R_1 \rightarrow R_2$ is a quasi-compact morphism. Let $Z \subset R_2$ be the scheme theoretic image (see Morphisms, Definition 28.6.2) of $a : R_1 \rightarrow R_2$. Then*

$$(U, Z, s_2|_Z, t_2|_Z, c_2|_Z)$$

is a groupoid scheme over S .

Proof. The main difficulty is to show that $c_2|_{Z \times_{s_2, U, t_2} Z}$ maps into Z . Consider the commutative diagram

$$\begin{array}{ccc} R_1 \times_{s_1, U, t_1} R_1 & \longrightarrow & R_1 \\ \downarrow a \times a & & \downarrow \\ R_2 \times_{s_2, U, t_2} R_2 & \longrightarrow & R_2 \end{array}$$

By Varieties, Lemma 32.14.3 we see that the scheme theoretic image of $a \times a$ is $Z \times_{s_2, U, t_2} Z$. By the commutativity of the diagram we conclude that $Z \times_{s_2, U, t_2} Z$ maps into Z by the bottom horizontal arrow. As in the proof of Lemma 39.10.4 it is also true that $i_2(Z) \subset Z$ and that e_2 factors through Z . Hence we conclude as in the proof of that lemma. \square

Lemma 39.10.7. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume U is the spectrum of a field. Let $Z \subset U \times_S U$ be the reduced closed subscheme (see Schemes, Definition 25.12.5) whose underlying topological space is the closure of the image of $j = (t, s) : R \rightarrow U \times_S U$. Then $\text{pr}_{02}(Z \times_{\text{pr}_1, U, \text{pr}_0} Z) \subset Z$ set theoretically.*

Proof. As $(U, U \times_S U, \text{pr}_1, \text{pr}_0, \text{pr}_{02})$ is a groupoid scheme over S this is a special case of Lemma 39.10.3. But we can also prove it directly as follows.

Write $U = \text{Spec}(k)$. Denote R_s (resp. Z_s , resp. U_s^2) the scheme R (resp. Z , resp. $U \times_S U$) viewed as a scheme over k via s (resp. $\text{pr}_1|_Z$, resp. pr_1). Similarly, denote ${}_tR$ (resp. ${}_tZ$, resp. ${}_tU^2$) the scheme R (resp. Z , resp. $U \times_S U$) viewed as a scheme over k via t (resp. $\text{pr}_0|_Z$, resp. pr_0). The morphism j induces morphisms of schemes $j_s : R_s \rightarrow U_s^2$ and ${}_tj : {}_tR \rightarrow {}_tU^2$ over k . Consider the commutative diagram

$$\begin{array}{ccc} R_s \times_k {}_tR & \xrightarrow{c} & R \\ \downarrow j_s \times {}_tj & & \downarrow j \\ U_s^2 \times_k {}_tU^2 & \longrightarrow & U \times_S U \end{array}$$

By Varieties, Lemma 32.14.2 we see that the closure of the image of $j_s \times {}_tj$ is $Z_s \times_k {}_tZ$. By the commutativity of the diagram we conclude that $Z_s \times_k {}_tZ$ maps into Z by the bottom horizontal arrow. \square

Lemma 39.10.8. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume U is the spectrum of a perfect field. Let $Z \subset U \times_S U$ be the reduced closed subscheme (see Schemes, Definition 25.12.5) whose underlying topological space is the closure of the image of $j = (t, s) : R \rightarrow U \times_S U$. Then*

$$(U, Z, \text{pr}_0|_Z, \text{pr}_1|_Z, \text{pr}_{02}|_{Z \times_{\text{pr}_1, U, \text{pr}_0} Z})$$

is a groupoid scheme over S .

Proof. As $(U, U \times_S U, \text{pr}_1, \text{pr}_0, \text{pr}_{02})$ is a groupoid scheme over S this is a special case of Lemma 39.10.4. But we can also prove it directly as follows.

We first explain why the statement makes sense. Since U is the spectrum of a perfect field k , the scheme Z is geometrically reduced over k (via either projection), see Varieties, Lemma 32.4.3. Hence the scheme $Z \times_{\text{pr}_1, U, \text{pr}_0} Z \subset Z$ is reduced, see Varieties, Lemma 32.4.7. Hence by Lemma 39.10.7 we see that pr_{02} induces a morphism $Z \times_{\text{pr}_1, U, \text{pr}_0} Z \rightarrow Z$. Finally, it is clear that $\Delta_{U/S}$ factors through Z

and that the map $\sigma : U \times_S U \rightarrow U \times_S U, (x, y) \mapsto (y, x)$ preserves Z . Since $(U, U \times_S U, \text{pr}_0, \text{pr}_1, \text{pr}_{02}, \Delta_{U/S}, \sigma)$ satisfies the axioms of a groupoid, it follows that after restricting to Z they satisfy the axioms. \square

Lemma 39.10.9. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Assume U is the spectrum of a field and assume R is quasi-compact (equivalently s, t are quasi-compact). Let $Z \subset U \times_S U$ be the scheme theoretic image (see Morphisms, Definition 28.6.2) of $j = (t, s) : R \rightarrow U \times_S U$. Then*

$$(U, Z, \text{pr}_0|_Z, \text{pr}_1|_Z, \text{pr}_{02}|_{Z \times_{\text{pr}_1, U, \text{pr}_0} Z})$$

is a groupoid scheme over S .

Proof. As $(U, U \times_S U, \text{pr}_1, \text{pr}_0, \text{pr}_{02})$ is a groupoid scheme over S this is a special case of Lemma 39.10.6. But we can also prove it directly as follows.

The main difficulty is to show that $\text{pr}_{02}|_{Z \times_{\text{pr}_1, U, \text{pr}_0} Z}$ maps into Z . Write $U = \text{Spec}(k)$. Denote R_s (resp. Z_s , resp. U_s^2) the scheme R (resp. Z , resp. $U \times_S U$) viewed as a scheme over k via s (resp. $\text{pr}_1|_Z$, resp. pr_1). Similarly, denote ${}_tR$ (resp. ${}_tZ$, resp. ${}_tU^2$) the scheme R (resp. Z , resp. $U \times_S U$) viewed as a scheme over k via t (resp. $\text{pr}_0|_Z$, resp. pr_0). The morphism j induces morphisms of schemes $j_s : R_s \rightarrow U_s^2$ and ${}_tj : {}_tR \rightarrow {}_tU^2$ over k . Consider the commutative diagram

$$\begin{array}{ccc} R_s \times_k {}_tR & \xrightarrow{c} & R \\ j_s \times {}_tj \downarrow & & \downarrow j \\ U_s^2 \times_k {}_tU^2 & \longrightarrow & U \times_S U \end{array}$$

By Varieties, Lemma 32.14.3 we see that the scheme theoretic image of $j_s \times {}_tj$ is $Z_s \times_k {}_tZ$. By the commutativity of the diagram we conclude that $Z_s \times_k {}_tZ$ maps into Z by the bottom horizontal arrow. As in the proof of Lemma 39.10.8 it is also true that $\sigma(Z) \subset Z$ and that $\Delta_{U/S}$ factors through Z . Hence we conclude as in the proof of that lemma. \square

39.11. Slicing groupoids

The following lemma shows that we may slice a Cohen-Macaulay groupoid scheme in order to reduce the dimension of the fibres, provided that the dimension of the stabilizer is small. This is an essential step in the process of improving a given presentation of a quotient stack.

Situation 39.11.1. Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $g : U' \rightarrow U$ be a morphism of schemes. Let $u \in U$ be a point, and let $u' \in U'$ be a point such that $g(u') = u$. Given these data, denote (U', R', s', t', c') the restriction of (U, R, s, t, c) via the morphism g . Denote $G \rightarrow U$ the stabilizer group scheme of R , which is a locally closed subscheme of R . Denote h the composition

$$h = s \circ \text{pr}_1 : U' \times_{g, U, t} R \longrightarrow U.$$

Denote $F_u = s^{-1}(u)$ (scheme theoretic fibre), and G_u the scheme theoretic fibre of G over u . Similarly for R' we denote $F'_{u'} = (s')^{-1}(u')$. Because $g(u') = u$ we have

$$F'_{u'} = h^{-1}(u) \times_{\text{Spec}(\kappa(u))} \text{Spec}(\kappa(u')).$$

The point $e(u) \in R$ may be viewed as a point on G_u and F_u also, and $e'(u')$ is a point of R' (resp. $G'_{u'}$, resp. $F'_{u'}$) which maps to $e(u)$ in R (resp. G_u , resp. F_u).

Lemma 39.11.2. *Let S be a scheme. Let (U, R, s, t, c, e, i) be a groupoid scheme over S . Let $G \rightarrow U$ be the stabilizer group scheme. Assume s and t are Cohen-Macaulay and locally of finite presentation. Let $u \in U$ be a finite type point of the scheme U , see Morphisms, Definition 28.17.3. With notation as in Situation 39.11.1, set*

$$d_1 = \dim(G_u), \quad d_2 = \dim_{e(u)}(F_u).$$

If $d_2 > d_1$, then there exist an affine scheme U' and a morphism $g : U' \rightarrow U$ such that (with notation as in Situation 39.11.1)

- (1) g is an immersion
- (2) $u \in U'$,
- (3) g is locally of finite presentation,
- (4) the morphism $h : U' \times_{g,U,t} R \rightarrow U$ is Cohen-Macaulay at $(u, e(u))$, and
- (5) we have $\dim_{e'(u)}(F'_u) = d_2 - 1$.

Proof. Let $\text{Spec}(A) \subset U$ be an affine neighbourhood of u such that u corresponds to a closed point of U , see Morphisms, Lemma 28.17.4. Let $\text{Spec}(B) \subset R$ be an affine neighbourhood of $e(u)$ which maps via j into the open $\text{Spec}(A) \times_S \text{Spec}(A) \subset U \times_S U$. Let $\mathfrak{m} \subset A$ be the maximal ideal corresponding to u . Let $\mathfrak{q} \subset B$ be the prime ideal corresponding to $e(u)$. Pictures:

$$\begin{array}{ccc} B \xleftarrow{s} A & & B_{\mathfrak{q}} \xleftarrow{s} A_{\mathfrak{m}} \\ \uparrow t & \text{and} & \uparrow t \\ A & & A_{\mathfrak{m}} \end{array}$$

Note that the two induced maps $s, t : \kappa(\mathfrak{m}) \rightarrow \kappa(\mathfrak{q})$ are equal and isomorphisms as $s \circ e = t \circ e = \text{id}_U$. In particular we see that \mathfrak{q} is a maximal ideal as well. The ring maps $s, t : A \rightarrow B$ are of finite presentation and flat. By assumption the ring

$$\mathcal{O}_{F_u, e(u)} = B_{\mathfrak{q}}/s(\mathfrak{m})B_{\mathfrak{q}}$$

is Cohen-Macaulay of dimension d_2 . The equality of dimension holds by Morphisms, Lemma 28.29.1.

Let R'' be the restriction of R to $u = \text{Spec}(\kappa(u))$ via the morphism $\text{Spec}(\kappa(u)) \rightarrow U$. As $u \rightarrow U$ is locally of finite type, we see that $(\text{Spec}(\kappa(u)), R'', s'', t'', c'')$ is a groupoid scheme with s'', t'' locally of finite type, see Lemma 39.8.1. By Lemma 39.9.9 this implies that $\dim(G'') = \dim(R'')$. We also have $\dim(R'') = \dim_{e''}(R'') = \dim(\mathcal{O}_{R'', e''})$, see Lemma 39.9.8. By Groupoids, Lemma 38.16.4 we have $G'' = G_u$. Hence we conclude that $\dim(\mathcal{O}_{R'', e''}) = d_1$.

As a scheme R'' is

$$R'' = R \times_{(U \times_S U)} \left(\text{Spec}(\kappa(\mathfrak{m})) \times_S \text{Spec}(\kappa(\mathfrak{m})) \right)$$

Hence an affine open neighbourhood of e'' is the spectrum of the ring

$$B \otimes_{(A \otimes_S A)} (\kappa(\mathfrak{m}) \otimes \kappa(\mathfrak{m})) = B/s(\mathfrak{m})B + t(\mathfrak{m})B$$

We conclude that

$$\mathcal{O}_{R'', e''} = B_{\mathfrak{q}}/s(\mathfrak{m})B_{\mathfrak{q}} + t(\mathfrak{m})B_{\mathfrak{q}}$$

and so now we know that this ring has dimension d_1 .

We claim this implies we can find an element $f \in \mathfrak{m}$ such that

$$\dim(B_{\mathfrak{q}}/(s(\mathfrak{m})B_{\mathfrak{q}} + fB_{\mathfrak{q}}) < d_2$$

Namely, suppose $\mathfrak{n}_j \supset s(\mathfrak{m})B_{\mathfrak{q}}$, $j = 1, \dots, m$ correspond to the minimal primes of the local ring $B_{\mathfrak{q}}/s(\mathfrak{m})B_{\mathfrak{q}}$. There are finitely many as this ring is Noetherian (since it is essentially of finite type over a field – but also because a Cohen-Macaulay ring is Noetherian). By the Cohen-Macaulay condition we have $\dim(B_{\mathfrak{q}}/\mathfrak{n}_j) = d_2$, for example by Algebra, Lemma 10.100.4. Note that $\dim(B_{\mathfrak{q}}/(\mathfrak{n}_j + t(\mathfrak{m})B_{\mathfrak{q}})) \leq d_1$ as it is a quotient of the ring $\mathcal{O}_{R',e''} = B_{\mathfrak{q}}/s(\mathfrak{m})B_{\mathfrak{q}} + t(\mathfrak{m})B_{\mathfrak{q}}$ which has dimension d_1 . As $d_1 < d_2$ this implies that $\mathfrak{m} \not\subset t^{-1}(\mathfrak{n}_j)$. By prime avoidance, see Algebra, Lemma 10.14.2, we can find $f \in \mathfrak{m}$ with $t(f) \notin \mathfrak{n}_j$ for $j = 1, \dots, m$. For this choice of f we have the displayed inequality above, see Algebra, Lemma 10.59.11.

Set $A' = A/fA$ and $U' = \text{Spec}(A')$. Then it is clear that $U' \rightarrow U$ is an immersion, locally of finite presentation and that $u \in U'$. Thus (1), (2) and (3) of the lemma hold. The morphism

$$U' \times_{g,U,t} R \longrightarrow U$$

factors through $\text{Spec}(A)$ and corresponds to the ring map

$$B/t(f)B \longleftarrow A/(f) \otimes_{A,t} B \xleftarrow{s} A$$

Now, we see $t(f)$ is not a zerodivisor on $B_{\mathfrak{q}}/s(\mathfrak{m})B_{\mathfrak{q}}$ as this is a Cohen-Macaulay ring of positive dimension and f is not contained in any minimal prime, see for example Algebra, Lemma 10.100.2. Hence by Algebra, Lemma 10.124.5 we conclude that $s : A_{\mathfrak{m}} \rightarrow B_{\mathfrak{q}}/t(f)B_{\mathfrak{q}}$ is flat with fibre ring $B_{\mathfrak{q}}/(s(\mathfrak{m})B_{\mathfrak{q}} + t(f)B_{\mathfrak{q}})$ which is Cohen-Macaulay by Algebra, Lemma 10.100.2 again. This implies part (4) of the lemma. To see part (5) note that by Diagram (39.8.0.1) the fibre F'_u is equal to the fibre of h over u . Hence $\dim_{e'(u)}(F'_u) = \dim(B_{\mathfrak{q}}/(s(\mathfrak{m})B_{\mathfrak{q}} + t(f)B_{\mathfrak{q}}))$ by Morphisms, Lemma 28.29.1 and the dimension of this ring is $d_2 - 1$ by Algebra, Lemma 10.100.2 once more. This proves the final assertion of the lemma and we win. \square

Now that we know how to slice we can combine it with the preceding material to get the following “optimal” result. It is optimal in the sense that since G_u is a locally closed subscheme of F_u one always has the inequality $\dim(G_u) = \dim_{e(u)}(G_u) \leq \dim_{e(u)}(F_u)$ so it is not possible to slice more than in the lemma.

Lemma 39.11.3. *Let S be a scheme. Let (U, R, s, t, c, e, i) be a groupoid scheme over S . Let $G \rightarrow U$ be the stabilizer group scheme. Assume s and t are Cohen-Macaulay and locally of finite presentation. Let $u \in U$ be a finite type point of the scheme U , see Morphisms, Definition 28.17.3. With notation as in Situation 39.11.1 there exist an affine scheme U' and a morphism $g : U' \rightarrow U$ such that*

- (1) g is an immersion,
- (2) $u \in U'$,
- (3) g is locally of finite presentation,
- (4) the morphism $h : U' \times_{g,U,t} R \rightarrow U$ is Cohen-Macaulay and locally of finite presentation,
- (5) the morphisms $s', t' : R' \rightarrow U'$ are Cohen-Macaulay and locally of finite presentation, and
- (6) $\dim_{e(u)}(F'_u) = \dim(G'_u)$.

Proof. As s is locally of finite presentation the scheme F_u is locally of finite type over $\kappa(u)$. Hence $\dim_{e(u)}(F_u) < \infty$ and we may argue by induction on $\dim_{e(u)}(F_u)$.

If $\dim_{e(u)}(F_u) = \dim(G_u)$ there is nothing to prove. Assume $\dim_{e(u)}(F_u) > \dim(G_u)$. This means that Lemma 39.11.2 applies and we find a morphism $g : U' \rightarrow U$ which has properties (1), (2), (3), instead of (6) we have $\dim_{e(u)}(F'_u) < \dim_{e(u)}(F_u)$, and instead of (4) and (5) we have that the composition

$$h = s \circ \text{pr}_1 : U' \times_{g,U,t} R \longrightarrow U$$

is Cohen-Macaulay at the point $(u, e(u))$. We apply Remark 39.5.3 and we obtain an open subscheme $U'' \subset U'$ such that $U'' \times_{g,U,t} R \subset U' \times_{g,U,t} R$ is the largest open subscheme on which h is Cohen-Macaulay. Since $(u, e(u)) \in U'' \times_{g,U,t} R$ we see that $u \in U''$. Hence we may replace U' by U'' and assume that in fact h is Cohen-Macaulay everywhere! By Lemma 39.8.2 we conclude that s', t' are locally of finite presentation and Cohen-Macaulay (use Morphisms, Lemma 28.22.4 and More on Morphisms, Lemma 36.17.4).

By construction $\dim_{e'(u)}(F'_u) < \dim_{e(u)}(F_u)$, so we may apply the induction hypothesis to (U', R', s', t', c') and the point $u \in U'$. Note that u is also a finite type point of U' (for example you can see this using the characterization of finite type points from Morphisms, Lemma 28.17.4). Let $g' : U'' \rightarrow U'$ and $(U'', R'', s'', t'', c'')$ be the solution of the corresponding problem starting with (U', R', s', t', c') and the point $u \in U'$. We claim that the composition

$$g'' = g \circ g' : U'' \longrightarrow U$$

is a solution for the original problem. Properties (1), (2), (3), (5), and (6) are immediate. To see (4) note that the morphism

$$h'' = s \circ \text{pr}_1 : U'' \times_{g'',U,t} R \longrightarrow U$$

is locally of finite presentation and Cohen-Macaulay by an application of Lemma 39.8.4 (use More on Morphisms, Lemma 36.17.9 to see that Cohen-Macaulay morphisms are fppf local on the target). \square

In case the stabilizer group scheme has fibres of dimension 0 this leads to the following slicing lemma.

Lemma 39.11.4. *Let S be a scheme. Let (U, R, s, t, c, e, i) be a groupoid scheme over S . Let $G \rightarrow U$ be the stabilizer group scheme. Assume s and t are Cohen-Macaulay and locally of finite presentation. Let $u \in U$ be a finite type point of the scheme U , see Morphisms, Definition 28.17.3. Assume that $G \rightarrow U$ is locally quasi-finite. With notation as in Situation 39.11.1 there exist an affine scheme U' and a morphism $g : U' \rightarrow U$ such that*

- (1) g is an immersion,
- (2) $u \in U'$,
- (3) g is locally of finite presentation,
- (4) the morphism $h : U' \times_{g,U,t} R \rightarrow U$ is flat, locally of finite presentation, and locally quasi-finite, and
- (5) the morphisms $s', t' : R' \rightarrow U'$ are flat, locally of finite presentation, and locally quasi-finite.

Proof. Take $g : U' \rightarrow U$ as in Lemma 39.11.3. Since $h^{-1}(u) = F'_u$ we see that h has relative dimension ≤ 0 at $(u, e(u))$. Hence, by Remark 39.5.3, we obtain an open subscheme $U'' \subset U'$ such that $u \in U''$ and $U'' \times_{g,U,t} R$ is the maximal open subscheme of $U' \times_{g,U,t} R$ on which h has relative dimension ≤ 0 . After replacing U' by U'' we see that h has relative dimension ≤ 0 . This implies that h is locally quasi-finite by Morphisms, Lemma 28.30.5. Since it is still locally of finite presentation and Cohen-Macaulay we see that it is flat, locally of finite presentation and locally quasi-finite, i.e., (4) above holds. This implies that s' is flat, locally of finite presentation and locally quasi-finite as a base change of h , see Lemma 39.8.2. \square

39.12. Étale localization of groupoids

In this section we begin applying the étale localization techniques of More on Morphisms, Section 36.30 to groupoid schemes. More advanced material of this kind can be found in More on Groupoids in Spaces, Section 61.12. Lemma 39.12.2 will be used to prove results on algebraic spaces separated and quasi-finite over a scheme, namely Morphisms of Spaces, Proposition 49.44.2 and its corollary Morphisms of Spaces, Lemma 49.45.1.

Lemma 39.12.1. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $p \in S$ be a point, and let $u \in U$ be a point lying over p . Assume that*

- (1) $U \rightarrow S$ is locally of finite type,
- (2) $U \rightarrow S$ is quasi-finite at u ,
- (3) $U \rightarrow S$ is separated,
- (4) $R \rightarrow S$ is separated,
- (5) s, t are flat and locally of finite presentation, and
- (6) $s^{-1}(\{u\})$ is finite.

Then there exists an étale neighbourhood $(S', p') \rightarrow (S, p)$ with $\kappa(p) = \kappa(p')$ and a base change diagram

$$\begin{array}{ccccc}
 R' \amalg W' & \xlongequal{\quad} & S' \times_S R & \longrightarrow & R \\
 & & \downarrow t' & \downarrow s' & \downarrow t \\
 & & & & \downarrow s \\
 U' \amalg W & \xlongequal{\quad} & S' \times_S U & \longrightarrow & U \\
 & & \downarrow & & \downarrow \\
 & & S' & \longrightarrow & S
 \end{array}$$

where the equal signs are decompositions into open and closed subschemes such that

- (a) *there exists a point u' of U' mapping to u in U ,*
- (b) *the fibre $(U')_{p'}$ equals $t'((s')^{-1}(\{u'\}))$ set theoretically,*
- (c) *the fibre $(R')_{p'}$ equals $(s')^{-1}((U')_{p'})$ set theoretically,*
- (d) *the schemes U' and R' are finite over S' ,*
- (e) *we have $s'(R') \subset U'$ and $t'(R') \subset U'$,*
- (f) *we have $c'(R' \times_{s',U',t'} R') \subset R'$ where c' is the base change of c , and*
- (g) *the morphisms s', t', c' determine a groupoid structure by taking the system $(U', R', s'|_{R'}, t'|_{R'}, c'|_{R' \times_{s',U',t'} R'})$.*

Proof. Let us denote $f : U \rightarrow S$ the structure morphism of U . By assumption (6) we can write $s^{-1}(\{u\}) = \{r_1, \dots, r_n\}$. Since this set is finite, we see that s is quasi-finite at each of these finitely many inverse images, see Morphisms, Lemma 28.21.7. Hence we see that $f \circ s : R \rightarrow S$ is quasi-finite at each r_i (Morphisms, Lemma 28.21.12). Hence r_i is isolated in the fibre R_p , see Morphisms, Lemma 28.21.6. Write $t(\{r_1, \dots, r_n\}) = \{u_1, \dots, u_m\}$. Note that it may happen that $m < n$ and note that $u \in \{u_1, \dots, u_m\}$. Since t is flat and locally of finite presentation, the morphism of fibres $t_p : R_p \rightarrow U_p$ is flat and locally of finite presentation (Morphisms, Lemmas 28.26.7 and 28.22.4), hence open (Morphisms, Lemma 28.26.9). The fact that each r_i is isolated in R_p implies that each $u_j = t(r_i)$ is isolated in U_p . Using Morphisms, Lemma 28.21.6 again, we see that f is quasi-finite at u_1, \dots, u_m .

Denote $F_u = s^{-1}(u)$ and $F_{u_j} = s^{-1}(u_j)$ the scheme theoretic fibres. Note that F_u is finite over $\kappa(u)$ as it is locally of finite type over $\kappa(u)$ with finitely many points (for example it follows from the much more general Morphisms, Lemma 28.50.8). By Lemma 39.6.1 we see that F_u and F_{u_j} become isomorphic over a common field extension of $\kappa(u)$ and $\kappa(u_j)$. Hence we see that F_{u_j} is finite over $\kappa(u_j)$. In particular we see $s^{-1}(\{u_j\})$ is a finite set for each $j = 1, \dots, m$. Thus we see that assumptions (2) and (6) hold for each u_j also (above we saw that $U \rightarrow S$ is quasi-finite at u_j). Hence the argument of the first paragraph applies to each u_j and we see that $R \rightarrow U$ is quasi-finite at each of the points of

$$\{r_1, \dots, r_N\} = s^{-1}(\{u_1, \dots, u_m\})$$

Note that $t(\{r_1, \dots, r_N\}) = \{u_1, \dots, u_m\}$ and $t^{-1}(\{u_1, \dots, u_m\}) = \{r_1, \dots, r_N\}$ since R is a groupoid². Moreover, we have $\text{pr}_0(c^{-1}(\{r_1, \dots, r_N\})) = \{r_1, \dots, r_N\}$ and $\text{pr}_1(c^{-1}(\{r_1, \dots, r_N\})) = \{r_1, \dots, r_N\}$. Similarly we get $e(\{u_1, \dots, u_m\}) \subset \{r_1, \dots, r_N\}$ and $i(\{r_1, \dots, r_N\}) = \{r_1, \dots, r_N\}$.

We may apply More on Morphisms, Lemma 36.30.4 to the pairs $(U \rightarrow S, \{u_1, \dots, u_m\})$ and $(R \rightarrow S, \{r_1, \dots, r_N\})$ to get an étale neighbourhood $(S', p') \rightarrow (S, p)$ which induces an identification $\kappa(p) = \kappa(p')$ such that $S' \times_S U$ and $S' \times_S R$ decompose as

$$S' \times_S U = U' \amalg W, \quad S' \times_S R = R' \amalg W'$$

with $U' \rightarrow S'$ finite and $(U')_{p'}$ mapping bijectively to $\{u_1, \dots, u_m\}$, and $R' \rightarrow S'$ finite and $(R')_{p'}$ mapping bijectively to $\{r_1, \dots, r_N\}$. Moreover, no point of $W_{p'}$ (resp. $(W')_{p'}$) maps to any of the points u_j (resp. r_i). At this point (a), (b), (c), and (d) of the lemma are satisfied. Moreover, the inclusions of (e) and (f) hold on fibres over p' , i.e., $s'((R')_{p'}) \subset (U')_{p'}$, $t'((R')_{p'}) \subset (U')_{p'}$, and $c'((R' \times_{s', U', t'} R')_{p'}) \subset (R')_{p'}$.

We claim that we can replace S' by a Zariski open neighbourhood of p' so that the inclusions of (e) and (f) hold. For example, consider the set $E = (s'|_{R'})^{-1}(W)$. This is open and closed in R' and does not contain any points of R' lying over p' . Since $R' \rightarrow S'$ is closed, after replacing S' by $S' \setminus (R' \rightarrow S')(E)$ we reach a situation where E is empty. In other words s' maps R' into U' . Note that this property is preserved under further shrinking S' . Similarly, we can arrange it so that t' maps R' into U' . At this point (e) holds. In the same manner, consider the

²Explanation in groupoid language: The original set $\{r_1, \dots, r_n\}$ was the set of arrows with source u . The set $\{u_1, \dots, u_m\}$ was the set of objects isomorphic to u . And $\{r_1, \dots, r_N\}$ is the set of all arrows between all the objects equivalent to u .

set $E = (c'|_{R' \times_{s', U', t'} R'})^{-1}(W')$. It is open and closed in the scheme $R' \times_{s', U', t'} R'$ which is finite over S' , and does not contain any points lying over p' . Hence after replacing S' by $S' \setminus (R' \times_{s', U', t'} R' \rightarrow S')(E)$ we reach a situation where E is empty. In other words we obtain the inclusion in (f). We may repeat the argument also with the identity $e' : S' \times_S U \rightarrow S' \times_S R$ and the inverse $i' : S' \times_S R \rightarrow S' \times_S U$ so that we may assume (after shrinking S' some more) that $(e'|_{U'})^{-1}(W') = \emptyset$ and $(i'|_{R'})^{-1}(W') = \emptyset$.

At this point we see that we may consider the structure

$$(U', R', s'|_{R'}, t'|_{R'}, c'|_{R' \times_{t', U', s'} R'}, e'|_{U'}, i'|_{R'}).$$

The axioms of a groupoid scheme over S' hold because they hold for the groupoid scheme $(S' \times_S U, S' \times_S R, s', t', c', e', i')$. □

Lemma 39.12.2. *Let S be a scheme. Let (U, R, s, t, c) be a groupoid scheme over S . Let $p \in S$ be a point, and let $u \in U$ be a point lying over p . Assume assumptions (1) – (6) of Lemma 39.12.1 hold as well as*

$$(7) \ j : R \rightarrow U \times_S U \text{ is universally closed}^3.$$

Then we can choose $(S', p') \rightarrow (S, p)$ and decompositions $S' \times_S U = U' \amalg W$ and $S' \times_S R = R' \amalg W'$ and $u' \in U'$ such that (a) – (g) of Lemma 39.12.1 hold as well as

$$(h) \ R' \text{ is the restriction of } S' \times_S R \text{ to } U'.$$

Proof. We apply Lemma 39.12.1 for the groupoid (U, R, s, t, c) over the scheme S with points p and u . Hence we get an étale neighbourhood $(S', p') \rightarrow (S, p)$ and disjoint union decompositions

$$S' \times_S U = U' \amalg W, \quad S' \times_S R = R' \amalg W'$$

and $u' \in U'$ satisfying conclusions (a), (b), (c), (d), (e), (f), and (g). We may shrink S' to a smaller neighbourhood of p' without affecting the conclusions (a) – (g). We will show that for a suitable shrinking conclusion (h) holds as well. Let us denote j' the base change of j to S' . By conclusion (e) it is clear that

$$j'^{-1}(U' \times_{S'} U') = R' \amalg Rest$$

for some open and closed $Rest$ piece. Since $U' \rightarrow S'$ is finite by conclusion (d) we see that $U' \times_{S'} U'$ is finite over S' . Since j is universally closed, also j' is universally closed, and hence $j'|_{Rest}$ is universally closed too. By conclusions (b) and (c) we see that the fibre of

$$(U' \times_{S'} U' \rightarrow S') \circ j'|_{Rest} : Rest \rightarrow S'$$

over p' is empty. Hence, since $Rest \rightarrow S'$ is closed as a composition of closed morphisms, after replacing S' by $S' \setminus \text{Im}(Rest \rightarrow S')$, we may assume that $Rest = \emptyset$. And this is exactly the condition that R' is the restriction of $S' \times_S R$ to the open subscheme $U' \subset S' \times_S U$, see Groupoids, Lemma 38.16.3 and its proof. □

³In view of the other conditions this is equivalent to requiring j to be proper.

39.13. Finite groupoids

A groupoid scheme (U, R, s, t, c) is sometimes called *finite* if the morphisms s and t are finite. This is potentially confusing as it doesn't imply that U or R or the quotient sheaf U/R is finite over anything.

Lemma 39.13.1. *Let (U, R, s, t, c) be a groupoid scheme over a scheme S . Assume s, t are finite. There exists a sequence of R -invariant closed subschemes*

$$U = Z_0 \supset Z_1 \supset Z_2 \supset \dots$$

such that $\bigcap Z_r = \emptyset$ and such that $s^{-1}(Z_{r-1}) \setminus s^{-1}(Z_r) \rightarrow Z_{r-1} \setminus Z_r$ is finite locally free of rank r .

Proof. Let $\{Z_r\}$ be the stratification of U given by the fitting ideals of the finite type quasi-coherent modules $s_*\mathcal{O}_R$. See More on Flatness, Lemma 37.20.3. Since the identity $e : U \rightarrow R$ is a section to s we see that $s_*\mathcal{O}_R$ contains \mathcal{O}_S as a direct summand. Hence $U = Z_{-1} = Z_0$ (details omitted). Since formation of fitting ideals commutes with base change (More on Algebra, Lemma 15.5.4) we find that $s^{-1}(Z_r)$ corresponds to the r th fitting ideal of $\mathrm{pr}_{1,*}\mathcal{O}_{R \times_s U, t, R}$ because the lower right square of diagram (39.3.0.2) is cartesian. Using the fact that the lower left square is also cartesian we conclude that $s^{-1}(Z_r) = t^{-1}(Z_r)$, in other words Z_r is R -invariant. The morphism $s^{-1}(Z_{r-1}) \setminus s^{-1}(Z_r) \rightarrow Z_{r-1} \setminus Z_r$ is finite locally free of rank r because the module $s_*\mathcal{O}_R$ pulls back to a finite locally free module of rank r on $Z_{r-1} \setminus Z_r$ by More on Flatness, Lemma 37.20.3. \square

Lemma 39.13.2. *Let (U, R, s, t, c) be a groupoid scheme over a scheme S . Assume s, t are finite. There exists an open subscheme $W \subset U$ and a closed subscheme $W' \subset W$ such that*

- (1) W and W' are R -invariant,
- (2) $U = t(s^{-1}(\overline{W}))$ set theoretically,
- (3) W is a thickening of W' , and
- (4) the maps s', t' of the restriction (W', R', s', t', c') are finite locally free.

Proof. Consider the stratification $U = Z_0 \supset Z_1 \supset Z_2 \supset \dots$ of Lemma 39.13.1.

We will construct disjoint unions $W = \coprod_{r \geq 1} W_r$ and $W' = \coprod_{r \geq 1} W'_r$ with each $W'_r \rightarrow W_r$ a thickening of R -invariant subschemes of U such that the morphisms s'_r, t'_r of the restrictions $(W'_r, R'_r, s'_r, t'_r, c'_r)$ are finite locally free of rank r . To begin we set $W_1 = W'_1 = U \setminus Z_1$. This is an R -invariant open subscheme of U , it is true that W_0 is a thickening of W'_0 , and the maps s'_1, t'_1 of the restriction $(W'_1, R'_1, s'_1, t'_1, c'_1)$ are isomorphisms, i.e., finite locally free of rank 1. Moreover, every point of $U \setminus Z_1$ is in $t(s^{-1}(\overline{W_1}))$.

Assume we have found subschemes $W'_r \subset W_r \subset U$ for $r \leq n$ such that

- (1) W_1, \dots, W_n are disjoint,
- (2) W_r and W'_r are R -invariant,
- (3) $U \setminus Z_n \subset \bigcup_{r \leq n} t(s^{-1}(\overline{W_r}))$ set theoretically,
- (4) W_r is a thickening of W'_r ,
- (5) the maps s'_r, t'_r of the restriction $(W'_r, R'_r, s'_r, t'_r, c'_r)$ are finite locally free of rank r .

Then we set

$$W_{n+1} = Z_n \setminus \left(Z_{n+1} \cup \bigcup_{r \leq n} t(s^{-1}(\overline{W_r})) \right)$$

set theoretically and

$$W'_{n+1} = Z_n \setminus \left(Z_{n+1} \cup \bigcup_{r \leq n} t(s^{-1}(\overline{W_r})) \right)$$

scheme theoretically. Then W_{n+1} is an R -invariant open subscheme of U because $Z_{n+1} \setminus \overline{U \setminus Z_{n+1}}$ is open in U and $\overline{U \setminus Z_{n+1}}$ is contained in the closed subset $\bigcup_{r \leq n} t(s^{-1}(\overline{W_r}))$ we are removing by property (3) and the fact that t is a closed morphism. It is clear that W'_{n+1} is a closed subscheme of W_{n+1} with the same underlying topological space. Finally, properties (1), (2) and (3) are clear and property (5) follows from Lemma 39.13.1.

By Lemma 39.13.1 we have $\bigcap Z_r = \emptyset$. Hence every point of U is contained in $U \setminus Z_n$ for some n . Thus we see that $U = \bigcup_{r \geq 1} t(s^{-1}(\overline{W_r}))$ set theoretically and we see that (2) holds. Thus $W' \subset W$ satisfy (1), (2), (3), and (4). \square

Let (U, R, s, t, c) be a groupoid scheme. Given a point $u \in U$ the R -orbit of u is the subset $t(s^{-1}(\{u\}))$ of U .

Lemma 39.13.3. *In Lemma 39.13.2 assume in addition that s and t are of finite presentation. Then*

- (1) *the morphism $W' \rightarrow W$ is of finite presentation, and*
- (2) *if $u \in U$ is a point whose R -orbit consists of generic points of irreducible components of U , then $u \in W$.*

Proof. In this case the stratification $U = Z_0 \supset Z_1 \supset Z_2 \supset \dots$ of Lemma 39.13.1 is given by closed immersions $Z_k \rightarrow U$ of finite presentation, see More on Flatness, Lemma 37.20.3. Part (1) follows immediately from this as $W' \rightarrow W$ is locally given by intersecting the open W by Z_r . To see part (2) let $\{u_1, \dots, u_n\}$ be the orbit of u . Since the closed subschemes Z_k are R -invariant and $\bigcap Z_k = \emptyset$, we find an k such that $u_i \in Z_k$ and $u_i \notin Z_{k+1}$ for all i . The image of $Z_k \rightarrow U$ and $Z_{k+1} \rightarrow U$ is locally constructible (Morphisms, Theorem 28.23.3). Since $u_i \in U$ is a generic point of an irreducible component of U , there exists an open neighbourhood U_i of u_i which is contained in $Z_k \setminus Z_{k+1}$ set theoretically (Properties, Lemma 27.2.2). In the proof of Lemma 39.13.2 we have constructed W as a disjoint union $\coprod W_r$ with $W_r \subset Z_{r-1} \setminus Z_r$ such that $U = \bigcup t(s^{-1}(\overline{W_r}))$. As $\{u_1, \dots, u_n\}$ is an R -orbit we see that $u \in t(s^{-1}(\overline{W_r}))$ implies $u_i \in \overline{W_r}$ for some i which implies $U_i \cap W_r \neq \emptyset$ which implies $r = k$. Thus we conclude that u is in

$$W_{k+1} = Z_k \setminus \left(Z_{k+1} \cup \bigcup_{r \leq k} t(s^{-1}(\overline{W_r})) \right)$$

as desired. \square

Lemma 39.13.4. *Let (U, R, s, t, c) be a groupoid scheme over a scheme S . Assume s, t are finite and of finite presentation and U quasi-separated. Let $u_1, \dots, u_m \in U$ be points whose orbits consist of generic points of irreducible components of U . Then there exist R -invariant subschemes $V' \subset V \subset U$ such that*

- (1) $u_1, \dots, u_m \in V'$,
- (2) V is open in U ,
- (3) V' and V are affine,
- (4) $V' \subset V$ is a thickening of finite presentation,
- (5) the morphisms s', t' of the restriction (V', R', s', t', c') are finite locally free.

Proof. Let $W' \subset W \subset U$ be as in Lemma 39.13.2. By Lemma 39.13.3 we get $u_j \in W$ and that $W' \rightarrow W$ is a thickening of finite presentation. By Limits, Lemma 31.10.3 it suffices to find an R -invariant affine open subscheme V' of W' containing u_j (because then we can let $V \subset W$ be the corresponding open subscheme which will be affine). Thus we may replace (U, R, s, t, c) by the restriction (W', R', s', t', c') to W' . In other words, we may assume we have a groupoid scheme (U, R, s, t, c) whose morphisms s and t are finite locally free. By Properties, Lemma 27.27.1 we can find an affine open containing the union of the orbits of u_1, \dots, u_m . Finally, we can apply Groupoids, Lemma 38.22.1 to conclude. \square

The following lemma is a special case of Lemma 39.13.4 but we redo the argument as it is slightly easier in this case (it avoids using Lemma 39.13.3).

Lemma 39.13.5. *Let (U, R, s, t, c) be a groupoid scheme over a scheme S . Assume s, t finite, U is locally Noetherian, and $u_1, \dots, u_m \in U$ points whose orbits consist of generic points of irreducible components of U . Then there exist R -invariant subschemes $V' \subset V \subset U$ such that*

- (1) $u_1, \dots, u_m \in V'$,
- (2) V is open in U ,
- (3) V' and V are affine,
- (4) $V' \subset V$ is a thickening,
- (5) the morphisms s', t' of the restriction (V', R', s', t', c') are finite locally free.

Proof. Let $\{u_{j1}, \dots, u_{jn_j}\}$ be the orbit of u_j . Let $W' \subset W \subset U$ be as in Lemma 39.13.2. Since $U = t(s^{-1}(\overline{W}))$ we see that at least one $u_{ji} \in \overline{W}$. Since u_{ji} is a generic point of an irreducible component and U locally Noetherian, this implies that $u_{ji} \in W$. Since W is R -invariant, we conclude that $u_j \in W$ and in fact the whole orbit is contained in W . By Cohomology of Schemes, Lemma 29.13.3 it suffices to find an R -invariant affine open subscheme V' of W' containing u_1, \dots, u_m (because then we can let $V \subset W$ be the corresponding open subscheme which will be affine). Thus we may replace (U, R, s, t, c) by the restriction (W', R', s', t', c') to W' . In other words, we may assume we have a groupoid scheme (U, R, s, t, c) whose morphisms s and t are finite locally free. By Properties, Lemma 27.27.1 we can find an affine open containing $\{u_{ij}\}$ (a locally Noetherian scheme is quasi-separated by Properties, Lemma 27.5.4). Finally, we can apply Groupoids, Lemma 38.22.1 to conclude. \square

Lemma 39.13.6. *Let (U, R, s, t, c) be a groupoid scheme over a scheme S with s, t integral. Let $g : U' \rightarrow U$ be an integral morphism such that every R -orbit in U meets $g(U')$. Let (U', R', s', t', c') be the restriction of R to U' . If $u' \in U'$ is contained in an R' -invariant affine open, then the image $u \in U$ is contained in an R -invariant affine open of U .*

Proof. Let $W' \subset U'$ be an R' -invariant affine open. Set $\tilde{R} = U' \times_{g, U, t} R$ with maps $\text{pr}_0 : \tilde{R} \rightarrow U'$ and $h = s \circ \text{pr}_1 : \tilde{R} \rightarrow U$. Observe that pr_0 and h are integral. It follows that $\tilde{W} = \text{pr}_0^{-1}(W')$ is affine. Since W' is R' -invariant, the image $W = h(\tilde{W})$ is set theoretically R -invariant and $\tilde{W} = h^{-1}(W)$ set theoretically (details omitted). Thus, if we can show that W is open, then W is a scheme and the morphism $\tilde{W} \rightarrow W$ is integral surjective which implies that W is affine by Limits, Proposition 31.10.2. However, our assumption on orbits meeting U' implies that $h : \tilde{R} \rightarrow U$ is surjective.

Since an integral surjective morphism is submersive (Topology, Lemma 5.5.5 and Morphisms, Lemma 28.44.7) it follows that W is open. \square

The following technical lemma produces “almost” invariant functions in the situation of a finite groupoid on a quasi-affine scheme.

Lemma 39.13.7. *Let (U, R, s, t, c) be a groupoid scheme with s, t finite and of finite presentation. Let $u_1, \dots, u_m \in U$ be points whose R -orbits consist of generic points of irreducible components of U . Let $j : U \rightarrow \text{Spec}(A)$ be an immersion. Let $I \subset A$ be an ideal such that $j(U) \cap V(I) = \emptyset$ and $V(I) \cup j(U)$ is closed in $\text{Spec}(A)$. Then there exists an $h \in I$ such that $j^{-1}D(h)$ is an R -invariant affine open subscheme of U containing u_1, \dots, u_m .*

Proof. Let $u_1, \dots, u_m \in V' \subset V \subset U$ be as in Lemma 39.13.4. Since $U \setminus V$ is closed in U , j an immersion, and $V(I) \cup j(U)$ is closed in $\text{Spec}(A)$, we can find an ideal $J \subset I$ such that $V(J) = V(I) \cup j(U \setminus V)$. For example we can take the ideal of elements of I which vanish on $j(U \setminus V)$. Thus we can replace (U, R, s, t, c) , $j : U \rightarrow \text{Spec}(A)$, and I by (V', R', s', t', c') , $j|_{V'} : V' \rightarrow \text{Spec}(A)$, and J . In other words, we may assume that U is affine and that s and t are finite locally free. Take any $f \in I$ which does not vanish at all the points in the R -orbits of u_1, \dots, u_m (Algebra, Lemma 10.14.2). Consider

$$g = \text{Norm}_s(t^\#(j^\#(f))) \in \Gamma(U, \mathcal{O}_U)$$

Since $f \in I$ and since $V(I) \cup j(U)$ is closed we see that $U \cap D(f) \rightarrow D(f)$ is a closed immersion. Hence $f^n g$ is the image of an element $h \in I$ for some $n > 0$. We claim that h works. Namely, we have seen in Groupoids, Lemma 38.21.2 that g is an R -invariant function, hence $D(g) \subset U$ is R -invariant. Since f does not vanish on the orbit of u_j , the function g does not vanish at u_j . Moreover, we have $V(g) \supset V(j^\#(f))$ and hence $j^{-1}D(h) = D(g)$. \square

Lemma 39.13.8. *Let (U, R, s, t, c) be a groupoid scheme. If s, t are quasi-finite, and $u, u' \in R$ are distinct points in the same orbit, then u' is not a specialization of u .*

Proof. Let $r \in R$ with $s(r) = u$ and $t(r) = u'$. If $u \rightsquigarrow u'$ then we can find a nontrivial specialization $r \rightsquigarrow r'$ with $s(r') = u'$, see Schemes, Lemma 25.19.8. Set $u'' = t(r')$. Note that $u'' \neq u'$ as there are no specializations in the fibres of a quasi-finite morphism. Hence we can continue and find a nontrivial specialization $r' \rightsquigarrow r''$ with $s(r'') = u''$, etc. This shows that the orbit of u contains an infinite sequence $u \rightsquigarrow u' \rightsquigarrow u'' \rightsquigarrow \dots$ of specializations which is nonsense as the orbit $t(s^{-1}(\{u\}))$ is finite. \square

Lemma 39.13.9. *Let $j : V \rightarrow \text{Spec}(A)$ be a quasi-compact immersion of schemes. Let $f \in A$ be such that $j^{-1}D(f)$ is affine and $j(V) \cap V(f)$ is closed. Then V is affine.*

Proof. We encourage the reader to find their own proof of this lemma. Let $A' = \Gamma(V, \mathcal{O}_V)$. Then $j' : V \rightarrow \text{Spec}(A')$ is a quasi-compact open immersion, see Properties, Lemma 27.15.4. Let $f' \in A'$ be the image of f . Then $(j')^{-1}D(f') = j^{-1}D(f)$ is affine. On the other hand, $j'(V) \cap V(f')$ is a subscheme of $\text{Spec}(A')$ which maps isomorphically to the closed subscheme $j(V) \cap V(f)$ of $\text{Spec}(A)$. Hence it is closed

in $\text{Spec}(A')$ for example by Schemes, Lemma 25.21.12. Thus we may replace A by A' and assume that j is an open immersion and $A = \Gamma(V, \mathcal{O}_V)$.

In this case we claim that $j(V) = \text{Spec}(A)$ which finishes the proof. If not, then we can find a principal affine open $D(g) \subset \text{Spec}(A)$ which meets the complement and avoids the closed subset $j(V) \cap V(f)$. Note that j maps $j^{-1}D(f)$ isomorphically onto $D(f)$, see Properties, Lemma 27.15.3. Hence $D(g)$ meets $V(f)$. On the other hand, $j^{-1}D(g)$ is a principal open of the affine open $j^{-1}D(f)$ hence affine. Hence by Properties, Lemma 27.15.3 again we see that $D(g)$ is isomorphic to $j^{-1}D(g) \subset j^{-1}D(f)$ which implies that $D(g) \subset D(f)$. This contradiction finishes the proof. \square

Lemma 39.13.10. *Let (U, R, s, t, c) be a groupoid scheme. Let $u \in U$. Assume*

- (1) *s, t are finite morphisms,*
- (2) *U is separated and locally Noetherian,*
- (3) *$\dim(\mathcal{O}_{U, u'}) \leq 1$ for every point u' in the orbit of u .*

Then u is contained in an R -invariant affine open of U .

Proof. The R -orbit of u is finite. By conditions (2) and (3) it is contained in an affine open U' of U , see Varieties, Proposition 32.22.7. Then $t(s^{-1}(U \setminus U'))$ is an R -invariant closed subset of U which does not contain u . Thus $U \setminus t(s^{-1}(U \setminus U'))$ is an R -invariant open of U' containing u . Replacing U by this open we may assume U is quasi-affine.

By Lemma 39.13.6 we may replace U by its reduction and assume U is reduced. This means R -invariant subschemes $W' \subset W \subset U$ of Lemma 39.13.2 are equal $W' = W$. As $U = t(s^{-1}(\overline{W}))$ some point u' of the R -orbit of u is contained in \overline{W} and by Lemma 39.13.6 we may replace U by \overline{W} and u by u' . Hence we may assume there is a dense open R -invariant subscheme $W \subset U$ such that the morphisms s_W, t_W of the restriction (W, R_W, s_W, t_W, c_W) are finite locally free.

If $u \in W$ then we are done by Groupoids, Lemma 38.22.1 (because W is quasi-affine so any finite set of points of W is contained in an affine open, see Properties, Lemma 27.27.5). Thus we assume $u \notin W$ and hence none of the points of the orbit of u is in W . Let $\xi \in U$ be a point with a nontrivial specialization to a point u' in the orbit of u . Since there are no specializations among the points in the orbit of u (Lemma 39.13.8) we see that ξ is not in the orbit. By assumption (3) we see that ξ is a generic point of U and hence $\xi \in W$. As U is Noetherian there are finitely many of these points $\xi_1, \dots, \xi_m \in W$. Because s_W, t_W are flat the orbit of each ξ_j consists of generic points of irreducible components of W (and hence U).

Let $j : U \rightarrow \text{Spec}(A)$ be an immersion of U into an affine scheme (this is possible as U is quasi-affine). Let $J \subset A$ be an ideal such that $V(J) \cap j(W) = \emptyset$ and $V(J) \cup j(W)$ is closed. Apply Lemma 39.13.7 to the groupoid scheme (W, R_W, s_W, t_W, c_W) , the morphism $j|_W : W \rightarrow \text{Spec}(A)$, the points ξ_j , and the ideal J to find an $f \in J$ such that $(j|_W)^{-1}D(f)$ is an R_W -invariant affine open containing ξ_j for all j . Since $f \in J$ we see that $j^{-1}D(f) \subset W$, i.e., $j^{-1}D(f)$ is an R -invariant affine open of U contained in W containing all ξ_j .

Let Z be the reduced induced closed subscheme structure on

$$U \setminus j^{-1}D(f) = j^{-1}V(f).$$

Then Z is set theoretically R -invariant (but it may not be scheme theoretically R -invariant). Let (Z, R_Z, s_Z, t_Z, c_Z) be the restriction of R to Z . Since $Z \rightarrow U$ is

finite, it follows that s_Z and t_Z are finite. Since $u \in Z$ the orbit of u is in Z and agrees with the R_Z -orbit of u viewed as a point of Z . Since $\dim(\mathcal{O}_{U,u'}) \leq 1$ and since $\xi_j \notin Z$ for all j , we see that $\dim(\mathcal{O}_{Z,u'}) \leq 0$ for all u' in the orbit of u . In other words, the R_Z -orbit of u consists of generic points of irreducible components of Z .

Let $I \subset A$ be an ideal such that $V(I) \cap j(U) = \emptyset$ and $V(I) \cup j(U)$ is closed. Apply Lemma 39.13.7 to the groupoid scheme (Z, R_Z, s_Z, t_Z, c_Z) , the restriction $j|_Z$, the ideal I , and the point $u \in Z$ to obtain $h \in I$ such that $j^{-1}D(h) \cap Z$ is an R_Z -invariant open affine containing u .

Consider the R_W -invariant (Groupoids, Lemma 38.21.2) function

$$g = \text{Norm}_{s_W}(t_W^\sharp(j^\sharp(h)|_W)) \in \Gamma(W, \mathcal{O}_W)$$

(In the following we only need the restriction of g to $j^{-1}D(f)$ and in this case the norm is along a finite locally free morphism of affines.) We claim that

$$V = (W_g \cap j^{-1}D(f)) \cup (j^{-1}D(h) \cap Z)$$

is an R -invariant affine open of U which finishes the proof of the lemma. It is set theoretically R -invariant by construction. As V is a constructible set, to see that it is open it suffices to show it is closed under generalization in U (Topology, Lemma 5.18.9 or the more general Topology, Lemma 5.22.5). Since $W_g \cap j^{-1}D(f)$ is open in U , it suffices to consider a specialization $u_1 \rightsquigarrow u_2$ of U with $u_2 \in j^{-1}D(h) \cap Z$. This means that h is nonzero in $j(u_2)$ and $u_2 \in Z$. If $u_1 \in Z$, then $j(u_1) \rightsquigarrow j(u_2)$ and since h is nonzero in $j(u_2)$ it is nonzero in $j(u_1)$ which implies $u_1 \in V$. If $u_1 \notin Z$ and also not in $W_g \cap j^{-1}D(f)$, then $u_1 \in W$, $u_1 \notin W_g$ because the complement of $Z = j^{-1}V(f)$ is contained in $W \cap j^{-1}D(f)$. Hence there exists a point $r_1 \in R$ with $s(r_1) = u_1$ such that h is zero in $t(r_1)$. Since s is finite we can find a specialization $r_1 \rightsquigarrow r_2$ with $s(r_2) = u_2$. However, then we conclude that f is zero in $u_2' = t(r_2)$ which contradicts the fact that $j^{-1}D(h) \cap Z$ is R -invariant and u_2 is in it. Thus V is open.

Observe that $V \subset j^{-1}D(h)$ for our function $h \in I$. Thus we obtain an immersion

$$j' : V \longrightarrow \text{Spec}(A_h)$$

Let $f' \in A_h$ be the image of f . Then $(j')^{-1}D(f')$ is the principal open determined by g in the affine open $j^{-1}D(f)$ of U . Hence $(j')^{-1}D(f')$ is affine. Finally, $j'(V) \cap V(f') = j'(j^{-1}D(h) \cap Z)$ is closed in $\text{Spec}(A_h/(f')) = \text{Spec}((A/f)_h) = D(h) \cap V(f)$ by our choice of $h \in I$ and the ideal I . Hence we can apply Lemma 39.13.9 to conclude that V is affine as claimed above. \square

39.14. Descending ind-quasi-affine morphisms

Ind-quasi-affine morphisms were defined in More on Morphisms, Section 36.46. This section is the analogue of Descent, Section 34.34 for ind-quasi-affine-morphisms.

Let X be a quasi-separated scheme. Let $E \subset X$ be a subset which is an intersection of a nonempty family of quasi-compact opens of X . Say $E = \bigcap_{i \in I} U_i$ with $U_i \subset X$ quasi-compact open and I nonempty. By adding finite intersections we may assume that for $i, j \in I$ there exists a $k \in I$ with $U_k \subset U_i \cap U_j$. In this situation we have

$$(39.14.0.1) \quad \Gamma(E, \mathcal{F}|_E) = \text{colim } \Gamma(U_i, \mathcal{F}|_{U_i})$$

for any sheaf \mathcal{F} defined on X . Namely, fix $i_0 \in I$ and replace X by U_{i_0} and I by $\{i \in I \mid U_i \subset U_{i_0}\}$. Then X is quasi-compact and quasi-separated, hence a spectral space, see Properties, Lemma 27.2.4. Then we see the equality holds by Topology, Lemma 5.23.7 and Sheaves, Lemma 6.29.4. (In fact, the formula holds for higher cohomology groups as well if \mathcal{F} is abelian, see Cohomology, Lemma 20.20.2.)

Lemma 39.14.1. *Let X be an ind-quasi-affine scheme. Let $E \subset X$ be an intersection of a nonempty family of quasi-compact opens of X . Set $A = \Gamma(E, \mathcal{O}_X|_E)$ and $Y = \text{Spec}(A)$. Then the canonical morphism*

$$j : (E, \mathcal{O}_X|_E) \longrightarrow (Y, \mathcal{O}_Y)$$

of Schemes, Lemma 25.6.4 determines an isomorphism $(E, \mathcal{O}_X|_E) \rightarrow (E', \mathcal{O}_Y|_{E'})$ where $E' \subset Y$ is an intersection of quasi-compact opens. If $W \subset E$ is open in X , then $j(W)$ is open in Y .

Proof. Note that $(E, \mathcal{O}_X|_E)$ is a locally ringed space so that Schemes, Lemma 25.6.4 applies to $A \rightarrow \Gamma(E, \mathcal{O}_X|_E)$. Write $E = \bigcap_{i \in I} U_i$ with $I \neq \emptyset$ and $U_i \subset X$ quasi-compact open. We may and do assume that for $i, j \in I$ there exists a $k \in I$ with $U_k \subset U_i \cap U_j$. Set $A_i = \Gamma(U_i, \mathcal{O}_{U_i})$. We obtain commutative diagrams

$$\begin{array}{ccc} (E, \mathcal{O}_X|_E) & \longrightarrow & (\text{Spec}(A), \mathcal{O}_{\text{Spec}(A)}) \\ \downarrow & & \downarrow \\ (U_i, \mathcal{O}_{U_i}) & \longrightarrow & (\text{Spec}(A_i), \mathcal{O}_{\text{Spec}(A_i)}) \end{array}$$

Since U_i is quasi-affine, we see that $U_i \rightarrow \text{Spec}(A_i)$ is a quasi-compact open immersion. On the other hand $A = \text{colim } A_i$. Hence $\text{Spec}(A) = \lim \text{Spec}(A_i)$ as topological spaces (Limits, Lemma 31.3.2). Since $E = \lim U_i$ (by Topology, Lemma 5.23.7) we see that $E \rightarrow \text{Spec}(A)$ is a homeomorphism onto its image E' and that E' is the intersection of the inverse images of the opens $U_i \subset \text{Spec}(A_i)$ in $\text{Spec}(A)$. For any $e \in E$ the local ring $\mathcal{O}_{X,e}$ is the value of $\mathcal{O}_{U_i,e}$ which is the same as the value on $\text{Spec}(A)$.

To prove the final assertion of the lemma we argue as follows. Pick $i, j \in I$ with $U_i \subset U_j$. Consider the following commutative diagrams

$$\begin{array}{ccccc} U_i & \longrightarrow & \text{Spec}(A_i) & & W & \longrightarrow & \text{Spec}(A_i) & & W & \longrightarrow & \text{Spec}(A) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\ U_i & \longrightarrow & \text{Spec}(A_j) & & W & \longrightarrow & \text{Spec}(A_j) & & W & \longrightarrow & \text{Spec}(A_j) \end{array}$$

By Properties, Lemma 27.15.5 the first diagram is cartesian. Hence the second is cartesian as well. Passing to the limit we find that the third diagram is cartesian, so the top horizontal arrow of this diagram is an open immersion. \square

Lemma 39.14.2. *Suppose given a cartesian diagram*

$$\begin{array}{ccc} X & \longrightarrow & \text{Spec}(B) \\ f \downarrow & & \downarrow \\ Y & \longrightarrow & \text{Spec}(A) \end{array}$$

of schemes. Let $E \subset Y$ be an intersection of a nonempty family of quasi-compact opens of Y . Then

$$\Gamma(f^{-1}(E), \mathcal{O}_X|_{f^{-1}(E)}) = \Gamma(E, \mathcal{O}_Y|_E) \otimes_A B$$

provided Y is quasi-separated and $A \rightarrow B$ is flat.

Proof. Write $E = \bigcap_{i \in I} V_i$ with $V_i \subset Y$ quasi-compact open. We may and do assume that for $i, j \in I$ there exists a $k \in I$ with $V_k \subset V_i \cap V_j$. Then we have similarly that $f^{-1}(E) = \bigcap_{i \in I} f^{-1}(V_i)$ in X . Thus the result follows from equation (39.14.0.1) and the corresponding result for V_i and $f^{-1}(V_i)$ which is Cohomology of Schemes, Lemma 29.5.2. \square

Lemma 39.14.3 (Gabber). *Let S be a scheme. Let $\{X_i \rightarrow S\}_{i \in I}$ be an fpqc covering. Let $(V_i/X_i, \varphi_{ij})$ be a descent datum relative to $\{X_i \rightarrow S\}$, see Descent, Definition 34.30.3. If each morphism $V_i \rightarrow X_i$ is ind-quasi-affine, then the descent datum is effective.*

Proof. Being ind-quasi-affine is a property of morphisms of schemes which is preserved under any base change, see More on Morphisms, Lemma 36.46.2. Hence Descent, Lemma 34.32.2 applies and it suffices to prove the statement of the lemma in case the fpqc-covering is given by a single $\{X \rightarrow S\}$ flat surjective morphism of affines. Say $X = \text{Spec}(A)$ and $S = \text{Spec}(R)$ so that $R \rightarrow A$ is a faithfully flat ring map. Let (V, φ) be a descent datum relative to X over S and assume that $V \rightarrow X$ is ind-quasi-affine, in other words, V is ind-quasi-affine.

Let (U, R, s, t, c) be the groupoid scheme over S with $U = X$ and $R = X \times_S X$ and s, t, c as usual. By Groupoids, Lemma 38.19.3 the pair (V, φ) corresponds to a cartesian morphism $(U', R', s', t', c') \rightarrow (U, R, s, t, c)$ of groupoid schemes. Let $u' \in U'$ be any point. By Groupoids, Lemmas 38.17.2, 38.17.3, and 38.17.4 we can choose $u' \in W \subset E \subset U'$ where W is open and R' -invariant, and E is set-theoretically R' -invariant and an intersection of a nonempty family of quasi-compact opens.

Translating back to (V, φ) , for any $v \in V$ we can find $v \in W \subset E \subset V$ with the following properties: (a) W is open and $\varphi(W \times_S X) = X \times_S W$ and (b) E an intersection of quasi-compact opens and $\varphi(E \times_S X) = X \times_S E$ set-theoretically. Here we use the notation $E \times_S X$ to mean the inverse image of E in $V \times_S X$ by the projection morphism and similarly for $X \times_S E$. By Lemma 39.14.2 this implies that φ defines an isomorphism

$$\begin{aligned} \Gamma(E, \mathcal{O}_V|_E) \otimes_R A &= \Gamma(E \times_S X, \mathcal{O}_{V \times_S X}|_{E \times_S X}) \\ &\rightarrow \Gamma(X \times_S E, \mathcal{O}_{X \times_S V}|_{X \times_S E}) \\ &= A \otimes_R \Gamma(E, \mathcal{O}_V|_E) \end{aligned}$$

of $A \otimes_R A$ -algebras which we will call ψ . The cocycle condition for φ translates into the cocycle condition for ψ as in Descent, Definition 34.3.1 (details omitted). By Descent, Proposition 34.3.9 we find an R -algebra R' and an isomorphism $\chi : R' \otimes_R A \rightarrow \Gamma(E, \mathcal{O}_V|_E)$ of A -algebras, compatible with ψ and the canonical descent datum on $R' \otimes_R A$.

By Lemma 39.14.1 we obtain a canonical “embedding”

$$j : (E, \mathcal{O}_V|_E) \longrightarrow \text{Spec}(\Gamma(E, \mathcal{O}_V|_E)) = \text{Spec}(R' \otimes_R A)$$

of locally ringed spaces. The construction of this map is canonical and we get a commutative diagram

where j' and j'' come from the same construction applied to $E \times_S X \subset V \times_S X$ and $X \times_S E \subset X \times_S V$ via χ and the identifications used to construct ψ . It follows that $j(W)$ is an open subscheme of $\text{Spec}(R' \otimes_R A)$ whose inverse image under the two projections $\text{Spec}(R' \otimes_R A \otimes_R A) \rightarrow \text{Spec}(R' \otimes_R A)$ are equal. By Descent, Lemma 34.9.2 we find an open $W_0 \subset \text{Spec}(R')$ whose base change to $\text{Spec}(A)$ is $j(W)$. Contemplating the diagram above we see that the descent datum $(W, \varphi|_{W \times_S X})$ is effective. By Descent, Lemma 34.31.13 we see that our descent datum is effective. \square

Étale Morphisms of Schemes

40.1. Introduction

In this Chapter, we discuss étale morphisms of schemes. We illustrate some of the more important concepts by working with the Noetherian case. Our principal goal is to collect for the reader with enough commutative algebra results to start reading a treatise on étale cohomology. An auxiliary goal is to provide enough evidence to ensure that the reader stops calling the phrase “the étale topology of schemes” an exercise in general nonsense, if (s)he does indulge in such blasphemy.

We will refer to the other chapters of the stacks project for standard results in algebraic geometry (on schemes and commutative algebra). We will provide detailed proofs of the new results that we state here.

40.2. Conventions

In this chapter, frequently schemes will be assumed locally Noetherian and frequently rings will be assumed Noetherian. But in all the statements we will reiterate this when necessary, and make sure we list all the hypotheses! On the other hand, here are some general facts that we will use often and are useful to keep in mind:

- (1) A ring homomorphism $A \rightarrow B$ of finite type with A Noetherian is of finite presentation. See Algebra, Lemma 10.30.4.
- (2) A morphism (locally) of finite type between locally Noetherian schemes is automatically (locally) of finite presentation. See Morphisms, Lemma 28.22.9.
- (3) Add more like this here.

40.3. Unramified morphisms

We first define the notion of unramified morphisms for local rings, and then globalize it to get one for arbitrary schemes.

Definition 40.3.1. Let A, B be Noetherian local rings. A local homomorphism $A \rightarrow B$ is said to be *unramified homomorphism of local rings* if

- (1) $\mathfrak{m}_A B = \mathfrak{m}_B$,
- (2) $\kappa(\mathfrak{m}_B)$ is a finite separable extension of $\kappa(\mathfrak{m}_A)$, and
- (3) B is essentially of finite type over A (this means that B is the localization of a finite type A -algebra at a prime).

This is the local version of the definition in Algebra, Section 10.144. In that section a ring map $R \rightarrow S$ is defined to be unramified if and only if it is of finite type, and

$\Omega_{S/R} = 0$. It is shown in Algebra, Lemmas 10.144.5 and 10.144.7 that given a ring map $R \rightarrow S$ of finite type, and a prime \mathfrak{q} of S lying over $\mathfrak{p} \subset R$, then we have

$$R \rightarrow S \text{ is unramified at } \mathfrak{q} \Leftrightarrow \mathfrak{p}S_{\mathfrak{q}} = \mathfrak{q}S_{\mathfrak{q}} \text{ and } \kappa(\mathfrak{p}) \subset \kappa(\mathfrak{q}) \text{ finite separable}$$

Thus we see that for a local homomorphism of local rings the properties of our definition above are closely related to the question of being unramified. In fact, we have proved the following lemma.

Lemma 40.3.2. *Let $A \rightarrow B$ be of finite type with A a Noetherian ring. Let \mathfrak{q} be a prime of B lying over $\mathfrak{p} \subset A$. Then $A \rightarrow B$ is unramified at \mathfrak{q} if and only if $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}}$ is an unramified homomorphism of local rings.*

Proof. See discussion above. \square

We will characterize the property of being unramified in terms of completions. For a Noetherian local ring A we denote A^{\wedge} the completion of A with respect to the maximal ideal. It is also a Noetherian local ring, see Algebra, Lemma 10.93.10.

Lemma 40.3.3. *Let A, B be Noetherian local rings. Let $A \rightarrow B$ be a local homomorphism.*

- (1) *if $A \rightarrow B$ is an unramified homomorphism of local rings, then B^{\wedge} is a finite A^{\wedge} module,*
- (2) *if $A \rightarrow B$ is an unramified homomorphism of local rings and $\kappa(\mathfrak{m}_A) = \kappa(\mathfrak{m}_B)$, then $A^{\wedge} \rightarrow B^{\wedge}$ is surjective,*
- (3) *if $A \rightarrow B$ is an unramified homomorphism of local rings and $\kappa(\mathfrak{m}_A)$ is separably closed, then $A^{\wedge} \rightarrow B^{\wedge}$ is surjective,*
- (4) *if A and B are complete discrete valuation rings, then $A \rightarrow B$ is an unramified homomorphism of local rings if and only if the uniformizer for A maps to a uniformizer for B , and the residue field extension is finite separable (and B is essentially of finite type over A).*

Proof. Part (1) is a special case of Algebra, Lemma 10.93.18. For part (2), note that the $\kappa(\mathfrak{m}_A)$ -vector space $B^{\wedge}/\mathfrak{m}_A B^{\wedge}$ is generated by 1. Hence by Nakayama's lemma (Algebra, Lemma 10.19.1) the map $A^{\wedge} \rightarrow B^{\wedge}$ is surjective. Part (3) is a special case of part (2). Part (4) is immediate from the definitions. \square

Lemma 40.3.4. *Let A, B be Noetherian local rings. Let $A \rightarrow B$ be a local homomorphism such that B is essentially of finite type over A . The following are equivalent*

- (1) *$A \rightarrow B$ is an unramified homomorphism of local rings*
- (2) *$A^{\wedge} \rightarrow B^{\wedge}$ is an unramified homomorphism of local rings, and*
- (3) *$A^{\wedge} \rightarrow B^{\wedge}$ is unramified.*

Proof. The equivalence of (1) and (2) follows from the fact that $\mathfrak{m}_A A^{\wedge}$ is the maximal ideal of A^{\wedge} (and similarly for B) and faithful flatness of $B \rightarrow B^{\wedge}$. For example if $A^{\wedge} \rightarrow B^{\wedge}$ is unramified, then $\mathfrak{m}_A B^{\wedge} = (\mathfrak{m}_A B) B^{\wedge} = \mathfrak{m}_B B^{\wedge}$ and hence $\mathfrak{m}_A B = \mathfrak{m}_B$.

Assume the equivalent conditions (1) and (2). By Lemma 40.3.3 we see that $A^{\wedge} \rightarrow B^{\wedge}$ is finite. Hence $A^{\wedge} \rightarrow B^{\wedge}$ is of finite presentation, and by Algebra, Lemma 10.144.7 we conclude that $A^{\wedge} \rightarrow B^{\wedge}$ is unramified at $\mathfrak{m}_{B^{\wedge}}$. Since B^{\wedge} is local we conclude that $A^{\wedge} \rightarrow B^{\wedge}$ is unramified.

Assume (3). By Algebra, Lemma 10.144.5 we conclude that $A^\wedge \rightarrow B^\wedge$ is an unramified homomorphism of local rings, i.e., (2) holds. \square

Definition 40.3.5. (See Morphisms, Definition 28.36.1 for the definition in the general case.) Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be locally of finite type. Let $x \in X$.

- (1) We say f is *unramified at x* if $\mathcal{O}_{Y,f(x)} \rightarrow \mathcal{O}_{X,x}$ is an unramified homomorphism of local rings.
- (2) The morphism $f : X \rightarrow Y$ is said to be *unramified* if it is unramified at all points of X .

Let us prove that this definition agrees with the definition in the chapter on morphisms of schemes. This in particular guarantees that the set of points where a morphism is unramified is open.

Lemma 40.3.6. *Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be locally of finite type. Let $x \in X$. The morphism f is unramified at x in the sense of Definition 40.3.5 if and only if it is unramified in the sense of Morphisms, Definition 28.36.1.*

Proof. This follows from Lemma 40.3.2 and the definitions. \square

Here are some results on unramified morphisms. The formulations as given in this list apply only to morphisms locally of finite type between locally Noetherian schemes. In each case we give a reference to the general result as proved earlier in the project, but in some cases one can prove the result more easily in the Noetherian case. Here is the list:

- (1) Unramifiedness is local on the source and the target in the Zariski topology.
- (2) Unramified morphisms are stable under base change and composition. See Morphisms, Lemmas 28.36.5 and 28.36.4.
- (3) Unramified morphisms of schemes are locally quasi-finite and quasi-compact unramified morphisms are quasi-finite. See Morphisms, Lemma 28.36.10
- (4) Unramified morphisms have relative dimension 0. See Morphisms, Definition 28.30.1 and Morphisms, Lemma 28.30.5.
- (5) A morphism is unramified if and only if all its fibres are unramified. That is, unramifiedness can be checked on the scheme theoretic fibres. See Morphisms, Lemma 28.36.12.
- (6) Let X and Y be unramified over a base scheme S . Any S -morphism from X to Y is unramified. See Morphisms, Lemma 28.36.16.

40.4. Three other characterizations of unramified morphisms

The following theorem gives three equivalent notions of being unramified at a point. See Morphisms, Lemma 28.36.14 for (part of) the statement for general schemes.

Theorem 40.4.1. *Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be a morphism of schemes which is locally of finite type. Let x be a point of X . The following are equivalent*

- (1) f is unramified at x ,
- (2) the stalk $\Omega_{X/Y,x}$ of the module of relative differentials at x is trivial,

- (3) there exist open neighbourhoods U of x and V of $f(x)$, and a commutative diagram

$$\begin{array}{ccc} U & \xrightarrow{i} & \mathbf{A}_V^n \\ & \searrow & \swarrow \\ & V & \end{array}$$

where i is a closed immersion defined by a quasi-coherent sheaf of ideals \mathcal{I} such that the differentials dg for $g \in \mathcal{I}_{i(x)}$ generate $\Omega_{\mathbf{A}_V^n/V, i(x)}$, and

- (4) the diagonal $\Delta_{X/Y} : X \rightarrow X \times_Y X$ is a local isomorphism at x .

Proof. The equivalence of (1) and (2) is proved in Morphisms, Lemma 28.36.14.

If f is unramified at x , then f is unramified in an open neighbourhood of x ; this does not follow immediately from Definition 40.3.5 of this chapter but it does follow from Morphisms, Definition 28.36.1 which we proved to be equivalent in Lemma 40.3.6. Choose affine opens $V \subset Y$, $U \subset X$ with $f(U) \subset V$ and $x \in U$, such that f is unramified on U , i.e., $f|_U : U \rightarrow V$ is unramified. By Morphisms, Lemma 28.36.13 the morphism $U \rightarrow U \times_V U$ is an open immersion. This proves that (1) implies (4).

If $\Delta_{X/Y}$ is a local isomorphism at x , then $\Omega_{X/Y, x} = 0$ by Morphisms, Lemma 28.34.7. Hence we see that (4) implies (2). At this point we know that (1), (2) and (4) are all equivalent.

Assume (3). The assumption on the diagram combined with Morphisms, Lemma 28.34.15 show that $\Omega_{U/V, x} = 0$. Since $\Omega_{U/V, x} = \Omega_{X/Y, x}$ we conclude (2) holds.

Finally, assume that (2) holds. To prove (3) we may localize on X and Y and assume that X and Y are affine. Say $X = \text{Spec}(B)$ and $Y = \text{Spec}(A)$. The point $x \in X$ corresponds to a prime $\mathfrak{q} \subset B$. Our assumption is that $\Omega_{B/A, \mathfrak{q}} = 0$ (see Morphisms, Lemma 28.34.5 for the relationship between differentials on schemes and modules of differentials in commutative algebra). Since Y is locally Noetherian and f locally of finite type we see that A is Noetherian and $B \cong A[x_1, \dots, x_n]/(f_1, \dots, f_m)$, see Properties, Lemma 27.5.2 and Morphisms, Lemma 28.16.2. In particular, $\Omega_{B/A}$ is a finite B -module. Hence we can find a single $g \in B$, $g \notin \mathfrak{q}$ such that the principal localization $(\Omega_{B/A})_g$ is zero. Hence after replacing B by B_g we see that $\Omega_{B/A} = 0$ (formation of modules of differentials commutes with localization, see Algebra, Lemma 10.127.8). This means that $d(f_j)$ generate the kernel of the canonical map $\Omega_{A[x_1, \dots, x_n]/A} \otimes_A B \rightarrow \Omega_{B/A}$. Thus the surjection $A[x_1, \dots, x_n] \rightarrow B$ of A -algebras gives the commutative diagram of (3), and the theorem is proved. \square

How can we use this theorem? Well, here are a few remarks:

- (1) Suppose that $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ are two morphisms locally of finite type between locally Noetherian schemes. There is a canonical short exact sequence

$$f^*(\Omega_{Y/Z}) \rightarrow \Omega_{X/Z} \rightarrow \Omega_{X/Y} \rightarrow 0$$

see Morphisms, Lemma 28.34.9. The theorem therefore implies that if $g \circ f$ is unramified, then so is f . This is Morphisms, Lemma 28.36.16.

- (2) Since $\Omega_{X/Y}$ is isomorphic to the conormal sheaf of the diagonal morphism (Morphisms, Lemma 28.34.7) we see that if $X \rightarrow Y$ is a monomorphism of

locally Noetherian schemes and locally of finite type, then $X \rightarrow Y$ is unramified. In particular, open and closed immersions of locally Noetherian schemes are unramified. See Morphisms, Lemmas 28.36.7 and 28.36.8.

- (3) The theorem also implies that the set of points where a morphism $f : X \rightarrow Y$ (locally of finite type of locally Noetherian schemes) is not unramified is the support of the coherent sheaf $\Omega_{X/Y}$. This allows one to give a scheme theoretic definition to the “ramification locus”.

40.5. The functorial characterization of unramified morphisms

In basic algebraic geometry we learn that some classes of morphisms can be characterized functorially, and that such descriptions are quite useful. Unramified morphisms too have such a characterization.

Theorem 40.5.1. *Let $f : X \rightarrow S$ be a morphism of schemes. Assume S is a locally Noetherian scheme, and f is locally of finite type. Then the following are equivalent:*

- (1) f is unramified,
- (2) the morphism f is formally unramified: for any affine S -scheme T and subscheme T_0 of T defined by a square-zero ideal, the natural map

$$\mathrm{Hom}_S(T, X) \longrightarrow \mathrm{Hom}_S(T_0, X)$$

is injective.

Proof. See More on Morphisms, Lemma 36.4.8 for a more general statement and proof. What follows is a sketch of the proof in the current case.

Firstly, one checks both properties are local on the source and the target. This we may assume that S and X are affine. Say $X = \mathrm{Spec}(B)$ and $S = \mathrm{Spec}(R)$. Say $T = \mathrm{Spec}(C)$. Let J be the square-zero ideal of C with $T_0 = \mathrm{Spec}(C/J)$. Assume that we are given the diagram

$$\begin{array}{ccccc} & & B & & \\ & \nearrow & \downarrow \phi & \searrow \bar{\phi} & \\ R & \longrightarrow & C & \longrightarrow & C/J \end{array}$$

Secondly, one checks that the association $\phi' \mapsto \phi' - \phi$ gives a bijection between the set of liftings of $\bar{\phi}$ and the module $\mathrm{Der}_R(B, J)$. Thus, we obtain the implication (1) \Rightarrow (2) via the description of unramified morphisms having trivial module of differentials, see Theorem 40.4.1.

To obtain the reverse implication, consider the surjection $q : C = (B \otimes_R B)/I^2 \rightarrow B = C/J$ defined by the square zero ideal $J = I/I^2$ where I is the kernel of the multiplication map $B \otimes_R B \rightarrow B$. We already have a lifting $B \rightarrow C$ defined by, say, $b \mapsto b \otimes 1$. Thus, by the same reasoning as above, we obtain a bijective correspondence between liftings of $\mathrm{id} : B \rightarrow C/J$ and $\mathrm{Der}_R(B, J)$. The hypothesis therefore implies that the latter module is trivial. But we know that $J \cong \Omega_{B/R}$. Thus, B/R is unramified. \square

40.6. Topological properties of unramified morphisms

The first topological result that will be of utility to us is one which says that unramified and separated morphisms have “nice” sections. The material in this section does not require any Noetherian hypotheses.

Proposition 40.6.1. *Sections of unramified morphisms.*

- (1) *Any section of an unramified morphism is an open immersion.*
- (2) *Any section of a separated morphism is a closed immersion.*
- (3) *Any section of an unramified separated morphism is open and closed.*

Proof. Fix a base scheme S . If $f : X' \rightarrow X$ is any S -morphism, then the graph $\Gamma_f : X' \rightarrow X' \times_S X$ is obtained as the base change of the diagonal $\Delta_{X/S} : X \rightarrow X \times_S X$ via the projection $X' \times_S X \rightarrow X \times_S X$. If $g : X \rightarrow S$ is separated (resp. unramified) then the diagonal is a closed immersion (resp. open immersion) by Schemes, Definition 25.21.3 (resp. Morphisms, Lemma 28.36.13). Hence so is the graph as a base change (by Schemes, Lemma 25.18.2). In the special case $X' = S$, we obtain (1), resp. (2). Part (3) follows on combining (1) and (2). \square

We can now explicitly describe the sections of unramified morphisms.

Theorem 40.6.2. *Let Y be a connected scheme. Let $f : X \rightarrow Y$ be unramified and separated. Every section of f is an isomorphism onto a connected component. There exists a bijective correspondence*

$$\text{sections of } f \leftrightarrow \left\{ \begin{array}{l} \text{connected components } X' \text{ of } X \text{ such that} \\ \text{the induced map } X' \rightarrow Y \text{ is an isomorphism} \end{array} \right\}$$

In particular, given $x \in X$ there is at most one section passing through x .

Proof. Direct from Proposition 40.6.1 part (3). \square

The preceding theorem gives us some idea of the “rigidity” of unramified morphisms. Further indication is provided by the following proposition which, besides being intrinsically interesting, is also useful in the theory of the algebraic fundamental group (see [Gro71, Exposé V]). See also the more general Morphisms, Lemma 28.36.17.

Proposition 40.6.3. *Let S be a scheme. Let $\pi : X \rightarrow S$ be unramified and separated. Let Y be an S -scheme and $y \in Y$ a point. Let $f, g : Y \rightarrow X$ be two S -morphisms. Assume*

- (1) *Y is connected*
- (2) *$x = f(y) = g(y)$, and*
- (3) *the induced maps $f^\sharp, g^\sharp : \kappa(x) \rightarrow \kappa(y)$ on residue fields are equal.*

Then $f = g$.

Proof. The maps $f, g : Y \rightarrow X$ define maps $f', g' : Y \rightarrow X_Y = Y \times_S X$ which are sections of the structure map $X_Y \rightarrow Y$. Note that $f = g$ if and only if $f' = g'$. The structure map $X_Y \rightarrow Y$ is the base change of π and hence unramified and separated also (see Morphisms, Lemmas 28.36.5 and Schemes, Lemma 25.21.13). Thus according to Theorem 40.6.2 it suffices to prove that f' and g' pass through the same point of X_Y . And this is exactly what the hypotheses (2) and (3) guarantee, namely $f'(y) = g'(y) \in X_Y$. \square

Lemma 40.6.4. *Let S be a Noetherian scheme. Let $X \rightarrow S$ be a quasi-compact unramified morphism. Let $Y \rightarrow S$ be a morphism with Y Noetherian. Then $\text{Mor}_S(Y, X)$ is a finite set.*

Proof. Assume first $X \rightarrow S$ is separated (which is often the case in practice). Since Y is Noetherian it has finitely many connected components. Thus we may assume Y is connected. Choose a point $y \in Y$ with image $s \in S$. Since $X \rightarrow S$ is unramified and quasi-compact then fibre X_s is finite, say $X_s = \{x_1, \dots, x_n\}$ and $\kappa(s) \subset \kappa(x_i)$ is a finite field extension. See Morphisms, Lemma 28.36.10, 28.21.5, and 28.21.10. For each i there are at most finitely many $\kappa(s)$ -algebra maps $\kappa(x_i) \rightarrow \kappa(y)$ (by elementary field theory). Thus $\text{Mor}_S(Y, X)$ is finite by Proposition 40.6.3.

General case. There exists a nonempty open $U \subset X$ such that $X_U \rightarrow U$ is finite (in particular separated), see Morphisms, Lemma 28.47.1 (the lemma applies since we've already seen above that a quasi-compact unramified morphism is quasi-finite and since $X \rightarrow S$ is quasi-separated by Morphisms, Lemma 28.16.7). Let $Z \subset S$ be the reduced closed subscheme supported on the complement of U . By Noetherian induction, we see that $\text{Mor}_Z(Y_Z, X_Z)$ is finite (details omitted). By the result of the first paragraph the set $\text{Mor}_U(Y_U, X_U)$ is finite. Thus it suffices to show that

$$\text{Mor}_S(Y, X) \longrightarrow \text{Mor}_Z(Y_Z, X_Z) \times \text{Mor}_U(Y_U, X_U)$$

is injective. This follows from the fact that the set of points where two morphisms $a, b : Y \rightarrow X$ agree is open in Y , due to the fact that $\Delta : X \rightarrow X \times_S X$ is open, see Morphisms, Lemma 28.36.13. \square

40.7. Universally injective, unramified morphisms

Recall that a morphism of schemes $f : X \rightarrow Y$ is universally injective if any base change of f is injective (on underlying topological spaces), see Morphisms, Definition 28.12.1. Universally injective and unramified morphisms can be characterized as follows.

Lemma 40.7.1. *Let $f : X \rightarrow S$ be a morphism of schemes. The following are equivalent:*

- (1) f is unramified and a monomorphism,
- (2) f is unramified and universally injective,
- (3) f is locally of finite type and a monomorphism,
- (4) f is universally injective, locally of finite type, and formally unramified,
- (5) f is locally of finite type and X_y is either empty or $X_y \rightarrow y$ is an isomorphism for all $y \in Y$.

Proof. We have seen in More on Morphisms, Lemma 36.4.8 that being formally unramified and locally of finite type is the same thing as being unramified. Hence (4) is equivalent to (2). A monomorphism is certainly universally injective and formally unramified hence (3) implies (4). It is clear that (1) implies (3). Finally, if (2) holds, then $\Delta : X \rightarrow X \times_S X$ is both an open immersion (Morphisms, Lemma 28.36.13) and surjective (Morphisms, Lemma 28.12.2) hence an isomorphism, i.e., f is a monomorphism. In this way we see that (2) implies (1).

Condition (3) implies (5) because monomorphisms are preserved under base change (Schemes, Lemma 25.23.5) and because of the description of monomorphisms towards the spectra of fields in Schemes, Lemma 25.23.10. Condition (5) implies (4) by Morphisms, Lemmas 28.12.2 and 28.36.12. \square

This leads to the following useful characterization of closed immersions.

Lemma 40.7.2. *Let $f : X \rightarrow S$ be a morphism of schemes. The following are equivalent:*

- (1) f is a closed immersion,
- (2) f is a proper monomorphism,
- (3) f is proper, unramified, and universally injective,
- (4) f is universally closed, unramified, and a monomorphism,
- (5) f is universally closed, unramified, and universally injective,
- (6) f is universally closed, locally of finite type, and a monomorphism,
- (7) f is universally closed, universally injective, locally of finite type, and formally unramified.

Proof. The equivalence of (4) – (7) follows immediately from Lemma 40.7.1.

Let $f : X \rightarrow S$ satisfy (6). Then f is separated, see Schemes, Lemma 25.23.3 and has finite fibres. Hence More on Morphisms, Lemma 36.31.5 shows f is finite. Then Morphisms, Lemma 28.44.13 implies f is a closed immersion, i.e., (1) holds.

Note that (1) \Rightarrow (2) because a closed immersion is proper and a monomorphism (Morphisms, Lemma 28.42.6 and Schemes, Lemma 25.23.7). By Lemma 40.7.1 we see that (2) implies (3). It is clear that (3) implies (5). \square

Here is another result of a similar flavor.

Lemma 40.7.3. *Let $\pi : X \rightarrow S$ be a morphism of schemes. Let $s \in S$. Assume that*

- (1) π is finite,
- (2) π is unramified,
- (3) $\pi^{-1}(\{s\}) = \{x\}$, and
- (4) $\kappa(s) \subset \kappa(x)$ is purely inseparable¹.

Then there exists an open neighbourhood U of s such that $\pi|_{\pi^{-1}(U)} : \pi^{-1}(U) \rightarrow U$ is a closed immersion.

Proof. The question is local on S . Hence we may assume that $S = \text{Spec}(A)$. By definition of a finite morphism this implies $X = \text{Spec}(B)$. Note that the ring map $\varphi : A \rightarrow B$ defining π is a finite unramified ring map. Let $\mathfrak{p} \subset A$ be the prime corresponding to s . Let $\mathfrak{q} \subset B$ be the prime corresponding to x . By Conditions (2), (3) and (4) imply that $B_{\mathfrak{q}}/\mathfrak{p}B_{\mathfrak{q}} = \kappa(\mathfrak{p})$. Algebra, Lemma 10.40.11 we have $B_{\mathfrak{q}} = B_{\mathfrak{p}}$ (note that a finite ring map satisfies going up, see Algebra, Section 10.40.) Hence we see that $B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}} = \kappa(\mathfrak{p})$. As B is a finite A -module we see from Nakayama's lemma (see Algebra, Lemma 10.19.1) that $B_{\mathfrak{p}} = \varphi(A_{\mathfrak{p}})$. Hence (using the finiteness of B as an A -module again) there exists a $f \in A$, $f \notin \mathfrak{p}$ such that $B_f = \varphi(A_f)$ as desired. \square

The topological results presented above will be used to give a functorial characterization of étale morphisms similar to Theorem 40.5.1.

¹In view of condition (2) this is equivalent to $\kappa(s) = \kappa(x)$.

40.8. Examples of unramified morphisms

Here are a few examples.

Example 40.8.1. Let k be a field. Unramified quasi-compact morphisms $X \rightarrow \text{Spec}(k)$ are affine. This is true because X has dimension 0 and is Noetherian, hence is a finite discrete set, and each point gives an affine open, so X is a finite disjoint union of affines hence affine. Noether normalization forces X to be the spectrum of a finite k -algebra A . This algebra is a product of finite separable field extensions of k . Thus, an unramified quasi-compact morphism to $\text{Spec}(k)$ corresponds to a finite number of finite separable field extensions of k . In particular, an unramified morphism with a connected source and a one point target is forced to be a finite separable field extension. As we will see later, $X \rightarrow \text{Spec}(k)$ is étale if and only if it is unramified. Thus, in this case at least, we obtain a very easy description of the étale topology of a scheme. Of course, the cohomology of this topology is another story.

Example 40.8.2. Property (3) in Theorem 40.4.1 gives us a canonical source of examples for unramified morphisms. Fix a ring R and an integer n . Let $I = (g_1, \dots, g_m)$ be an ideal in $R[x_1, \dots, x_n]$. Let $\mathfrak{q} \subset R[x_1, \dots, x_n]$ be a prime. Assume $I \subset \mathfrak{q}$ and that the matrix

$$\left(\frac{\partial g_i}{\partial x_j} \right) \bmod \mathfrak{q} \in \text{Mat}(n \times m, \kappa(\mathfrak{q}))$$

has rank n . Then the morphism $f : Z = \text{Spec}(R[x_1, \dots, x_n]/I) \rightarrow \text{Spec}(R)$ is unramified at the point $x \in Z \subset \mathbf{A}_R^n$ corresponding to \mathfrak{q} . Clearly we must have $m \geq n$. In the extreme case $m = n$, i.e., the differential of the map $\mathbf{A}_R^n \rightarrow \mathbf{A}_R^n$ defined by the g_i 's is an isomorphism of the tangent spaces, then f is also flat at x and, hence, is an étale map (see Algebra, Definition 10.132.6, Lemma 10.132.7 and Example 10.132.8).

Example 40.8.3. Fix an extension of number fields L/K with rings of integers \mathcal{O}_L and \mathcal{O}_K . The injection $K \rightarrow L$ defines a morphism $f : \text{Spec}(\mathcal{O}_L) \rightarrow \text{Spec}(\mathcal{O}_K)$. As discussed above, the points where f is unramified in our sense correspond to the set of points where f is unramified in the conventional sense. In the conventional sense, the locus of ramification in $\text{Spec}(\mathcal{O}_L)$ can be defined by vanishing set of the different; this is an ideal in \mathcal{O}_L . In fact, the different is nothing but the annihilator of the module $\Omega_{\mathcal{O}_L/\mathcal{O}_K}$. Similarly, the discriminant is an ideal in \mathcal{O}_K , namely it is the norm of the different. The vanishing set of the discriminant is precisely the set of points of K which ramify in L . Thus, denoting by X the complement of the closed subset defined by the different in $\text{Spec}(\mathcal{O}_L)$, we obtain a morphism $X \rightarrow \text{Spec}(\mathcal{O}_L)$ which is unramified. Furthermore, this morphism is also flat, as any local homomorphism of discrete valuation rings is flat, and hence this morphism is actually étale. If L/K is Galois, then denoting by Y the complement of the closed subset defined by the discriminant in $\text{Spec}(\mathcal{O}_K)$, we see that we get even a finite étale morphism $X \rightarrow Y$. Thus, this is an example of a finite étale covering.

40.9. Flat morphisms

This section simply exists to summarize the properties of flatness that will be useful to us. Thus, we will be content with stating the theorems precisely and giving references for the proofs.

After briefly recalling the necessary facts about flat modules over Noetherian rings, we state a theorem of Grothendieck which gives sufficient conditions for “hyperplane sections” of certain modules to be flat.

Definition 40.9.1. Flatness of modules and rings.

- (1) A module N over a ring A is said to be *flat* if the functor $M \mapsto M \otimes_A N$ is exact.
- (2) If this functor is also faithful, we say that N is *faithfully flat* over A .
- (3) A morphism of rings $f : A \rightarrow B$ is said to be *flat* (*resp. faithfully flat*) if the functor $M \mapsto M \otimes_A B$ is exact (*resp. faithful and exact*).

Here is a list of facts with references to the algebra chapter.

- (1) Free and projective modules are flat. This is clear for free modules and follows for projective modules as they are direct summands of free modules and \otimes commutes with direct sums.
- (2) Flatness is a local property, that is, M is flat over A if and only if $M_{\mathfrak{p}}$ is flat over $A_{\mathfrak{p}}$ for all $\mathfrak{p} \in \text{Spec}(A)$. See Algebra, Lemma 10.38.19.
- (3) If M is a flat A -module and $A \rightarrow B$ is a ring map, then $M \otimes_A B$ is a flat B -module. See Algebra, Lemma 10.38.6.
- (4) Finite flat modules over local rings are free. See Algebra, Lemma 10.75.4.
- (5) If $f : A \rightarrow B$ is a morphism of arbitrary rings, f is flat if and only if the induced maps $A_{f^{-1}(\mathfrak{q})} \rightarrow B_{\mathfrak{q}}$ are flat for all $\mathfrak{q} \in \text{Spec}(B)$. See Algebra, Lemma 10.38.19.
- (6) If $f : A \rightarrow B$ is a local homomorphism of local rings, f is flat if and only if it is faithfully flat. See Algebra, Lemma 10.38.16.
- (7) A map $A \rightarrow B$ of rings is faithfully flat if and only if it is flat and the induced map on spectra is surjective. See Algebra, Lemma 10.38.15.
- (8) If A is a noetherian local ring, the completion A^{\wedge} is faithfully flat over A . See Algebra, Lemma 10.93.4.
- (9) Let A be a Noetherian local ring and M an A -module. Then M is flat over A if and only if $M \otimes_A A^{\wedge}$ is flat over A^{\wedge} . (Combine the previous statement with Algebra, Lemma 10.38.7.)

Before we move on to the geometric category, we present Grothendieck’s theorem, which provides a convenient recipe for producing flat modules.

Theorem 40.9.2. *Let A, B be Noetherian local rings. Let $f : A \rightarrow B$ be a local homomorphism. If M is a finite B -module that is flat as an A -module, and $t \in \mathfrak{m}_B$ is an element such that multiplication by t is injective on $M/\mathfrak{m}_A M$, then M/tM is also A -flat.*

Proof. See Algebra, Lemma 10.95.1. See also [Mat70, Section 20]. □

Definition 40.9.3. (See Morphisms, Definition 28.26.1). Let $f : X \rightarrow Y$ be a morphism of schemes. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module.

- (1) Let $x \in X$. We say \mathcal{F} is *flat over Y at $x \in X$* if \mathcal{F}_x is a flat $\mathcal{O}_{Y, f(x)}$ -module. This uses the map $\mathcal{O}_{Y, f(x)} \rightarrow \mathcal{O}_{X, x}$ to think of \mathcal{F}_x as a $\mathcal{O}_{Y, f(x)}$ -module.
- (2) Let $x \in X$. We say f is *flat at $x \in X$* if $\mathcal{O}_{Y, f(x)} \rightarrow \mathcal{O}_{X, x}$ is flat.
- (3) We say f is *flat* if it is flat at all points of X .
- (4) A morphism $f : X \rightarrow Y$ that is flat and surjective is sometimes said to be *faithfully flat*.

Once again, here is a list of results:

- (1) The property (of a morphism) of being flat is, by fiat, local in the Zariski topology on the source and the target.
- (2) Open immersions are flat. (This is clear because it induces isomorphisms on local rings.)
- (3) Flat morphisms are stable under base change and composition. Morphisms, Lemmas 28.26.7 and 28.26.5.
- (4) If $f : X \rightarrow Y$ is flat, then the pullback functor $QCoh(\mathcal{O}_Y) \rightarrow QCoh(\mathcal{O}_X)$ is exact. This is immediate by looking at stalks.
- (5) Let $f : X \rightarrow Y$ be a morphism of schemes, and assume Y is quasi-compact and quasi-separated. In this case if the functor f^* is exact then f is flat. (Proof omitted. Hint: Use Properties, Lemma 27.20.1 to see that Y has “enough” ideal sheaves and use the characterization of flatness in Algebra, Lemma 10.38.4.)

40.10. Topological properties of flat morphisms

We “recall” below some openness properties that flat morphisms enjoy.

Theorem 40.10.1. *Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be a morphism which is locally of finite type. Let \mathcal{F} be a coherent \mathcal{O}_X -module. The set of points in X where \mathcal{F} is flat over S is an open set. In particular the set of points where f is flat is open in X .*

Proof. See More on Morphisms, Theorem 36.12.1. □

Theorem 40.10.2. *Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be a morphism which is flat and locally of finite type. Then f is (universally) open.*

Proof. See Morphisms, Lemma 28.26.9. □

Theorem 40.10.3. *A faithfully flat quasi-compact morphism is a quotient map for the Zariski topology.*

Proof. See Morphisms, Lemma 28.26.10. □

An important reason to study flat morphisms is that they provide the adequate framework for capturing the notion of a family of schemes parametrized by the points of another scheme. Naively one may think that any morphism $f : X \rightarrow S$ should be thought of as a family parametrized by the points of S . However, without a flatness restriction on f , really bizarre things can happen in this so-called family. For instance, we aren’t guaranteed that relative dimension (dimension of the fibres) is constant in a family. Other numerical invariants, such as the Hilbert polynomial, too may change from fibre to fibre. Flatness prevents such things from happening and, therefore, provides some “continuity” to the fibres.

40.11. Étale morphisms

In this section, we will define étale morphisms and prove a number of important properties about them. The most important one, no doubt, is the functorial characterization presented in Theorem 40.16.1. Following this, we will also discuss a few properties of rings which are insensitive to an étale extension (properties which hold for a ring if and only if they hold for all its étale extensions) to motivate the

basic tenet of étale cohomology – étale morphisms are the algebraic analogue of local isomorphisms.

As the title suggests, we will define the class of étale morphisms – the class of morphisms (whose surjective families) we shall deem to be coverings in the category of schemes over a base scheme S in order to define the étale site $S_{\text{étale}}$. Intuitively, an étale morphism is supposed to capture the idea of a covering space and, therefore, should be close to a local isomorphism. If we're working with varieties over algebraically closed fields, this last statement can be made into a definition provided we replace “local isomorphism” with “formal local isomorphism” (isomorphism after completion). One can then give a definition over any base field by asking that the base change to the algebraic closure be étale (in the aforementioned sense). But, rather than proceeding via such aesthetically displeasing constructions, we will adopt a cleaner, albeit slightly more abstract, algebraic approach.

Definition 40.11.1. Let A, B be Noetherian local rings. A local homomorphism $f : A \rightarrow B$ is said to be a *étale homomorphism of local rings* if it is flat and unramified homomorphism of local rings (please see Definition 40.3.1).

This is the local version of the definition of an étale ring map in Algebra, Section 10.138. The exact definition given in that section is that it is a smooth ring map of relative dimension 0. It is shown (in Algebra, Lemma 10.138.2) that an étale R -algebra S always has a presentation

$$S = R[x_1, \dots, x_n]/(f_1, \dots, f_n)$$

such that

$$g = \det \begin{pmatrix} \partial f_1/\partial x_1 & \partial f_2/\partial x_1 & \dots & \partial f_n/\partial x_1 \\ \partial f_1/\partial x_2 & \partial f_2/\partial x_2 & \dots & \partial f_n/\partial x_2 \\ \dots & \dots & \dots & \dots \\ \partial f_1/\partial x_n & \partial f_2/\partial x_n & \dots & \partial f_n/\partial x_n \end{pmatrix}$$

maps to an invertible element in S . The following two lemmas link the two notions.

Lemma 40.11.2. *Let $A \rightarrow B$ be of finite type with A a Noetherian ring. Let \mathfrak{q} be a prime of B lying over $\mathfrak{p} \subset A$. Then $A \rightarrow B$ is étale at \mathfrak{q} if and only if $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}}$ is an étale homomorphism of local rings.*

Proof. See Algebra, Lemmas 10.138.3 (flatness of étale maps), 10.138.5 (étale maps are unramified) and 10.138.7 (flat and unramified maps are étale). \square

Lemma 40.11.3. *Let A, B be Noetherian local rings. Let $A \rightarrow B$ be a local homomorphism such that B is essentially of finite type over A . The following are equivalent*

- (1) $A \rightarrow B$ is an étale homomorphism of local rings
- (2) $A^\wedge \rightarrow B^\wedge$ is an étale homomorphism of local rings, and
- (3) $A^\wedge \rightarrow B^\wedge$ is étale.

Moreover, in this case $B^\wedge \cong (A^\wedge)^{\oplus n}$ as A^\wedge -modules for some $n \geq 1$.

Proof. To see the equivalences of (1), (2) and (3), as we have the corresponding results for unramified ring maps (Lemma 40.3.4) it suffices to prove that $A \rightarrow B$ is flat if and only if $A^\wedge \rightarrow B^\wedge$ is flat. This is clear from our lists of properties of flat maps since the ring maps $A \rightarrow A^\wedge$ and $B \rightarrow B^\wedge$ are faithfully flat. For the final statement, by Lemma 40.3.3 we see that B^\wedge is a finite flat A^\wedge module. Hence it is finite free by our list of properties on flat modules in Section 40.9. \square

The integer n which occurs in the lemma above is nothing other than the degree $[\kappa(\mathfrak{m}_B) : \kappa(\mathfrak{m}_A)]$ of the residue field extension. In particular, if $\kappa(\mathfrak{m}_A)$ is separably closed, we see that $A^\wedge \rightarrow B^\wedge$ is an isomorphism, which vindicates our earlier claims.

Definition 40.11.4. (See Morphisms, Definition 28.37.1.) Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be a morphism of schemes which is locally of finite type.

- (1) Let $x \in X$. We say f is *étale at* $x \in X$ if $\mathcal{O}_{Y,f(x)} \rightarrow \mathcal{O}_{X,x}$ is an étale homomorphism of local rings.
- (2) The morphism is said to be *étale* if it is étale at all its points.

Let us prove that this definition agrees with the definition in the chapter on morphisms of schemes. This in particular guarantees that the set of points where a morphism is étale is open.

Lemma 40.11.5. *Let Y be a locally Noetherian scheme. Let $f : X \rightarrow Y$ be locally of finite type. Let $x \in X$. The morphism f is étale at x in the sense of Definition 40.11.4 if and only if it is unramified at x in the sense of Morphisms, Definition 28.37.1.*

Proof. This follows from Lemma 40.11.2 and the definitions. □

Here are some results on étale morphisms. The formulations as given in this list apply only to morphisms locally of finite type between locally Noetherian schemes. In each case we give a reference to the general result as proved earlier in the project, but in some cases one can prove the result more easily in the Noetherian case. Here is the list:

- (1) An étale morphism is unramified. (Clear from our definitions.)
- (2) Étaleness is local on the source and the target in the Zariski topology.
- (3) Étale morphisms are stable under base change and composition. See Morphisms, Lemmas 28.37.4 and 28.37.3.
- (4) Étale morphisms of schemes are locally quasi-finite and quasi-compact étale morphisms are quasi-finite. (This is true because it holds for unramified morphisms as seen earlier.)
- (5) Étale morphisms have relative dimension 0. See Morphisms, Definition 28.30.1 and Morphisms, Lemma 28.30.5.
- (6) A morphism is étale if and only if it is flat and all its fibres are étale. See Morphisms, Lemma 28.37.8.
- (7) Étale morphisms are open. This is true because an étale morphism is flat, and Theorem 40.10.2.
- (8) Let X and Y be étale over a base scheme S . Any S -morphism from X to Y is étale. See Morphisms, Lemma 28.37.18.

40.12. The structure theorem

We present a theorem which describes the local structure of étale and unramified morphisms. Besides its obvious independent importance, this theorem also allows us to make the transition to another definition of étale morphisms that captures the geometric intuition better than the one we've used so far.

To state it we need the notion of a *standard étale ring map*, see Algebra, Definition 10.138.14. Namely, suppose that R is a ring and $f, g \in R[t]$ are polynomials such that

- (a) f is a monic polynomial, and
- (b) $f' = df/dt$ is invertible in the localization $R[t]_g/(f)$.

Then the map

$$R \longrightarrow R[t]_g/(f) = R[t, 1/g]/(f)$$

is a standard étale algebra, and any standard étale algebra is isomorphic to one of these. It is a pleasant exercise to prove that such a ring map is flat, and unramified and hence étale (as expected of course). A special case of a standard étale ring map is any ring map

$$R \longrightarrow R[t]_{f'}/(f) = R[t, 1/f']/(f)$$

with f a monic polynomial, and any standard étale algebra is (isomorphic to) a principal localization of one of these.

Theorem 40.12.1. *Let $f : A \rightarrow B$ be an étale homomorphism of local rings. Then there exist $f, g \in A[t]$ such that*

- (1) $B' = A[t]_g/(f)$ is standard étale – see (a) and (b) above, and
- (2) B is isomorphic to a localization of B' at a prime.

Proof. Write $B = B'_\mathfrak{q}$ for some finite type A -algebra B' (we can do this because B is essentially of finite type over A). By Lemma 40.11.2 we see that $A \rightarrow B'$ is étale at \mathfrak{q} . Hence we may apply Algebra, Proposition 10.138.17 to see that a principal localization of B' is standard étale. \square

Here is the version for unramified homomorphisms of local rings.

Theorem 40.12.2. *Let $f : A \rightarrow B$ be an unramified morphism of local rings. Then there exist $f, g \in A[t]$ such that*

- (1) $B' = A[t]_g/(f)$ is standard étale – see (a) and (b) above, and
- (2) B is isomorphic to a quotient of a localization of B' at a prime.

Proof. Write $B = B'_\mathfrak{q}$ for some finite type A -algebra B' (we can do this because B is essentially of finite type over A). By Lemma 40.3.2 we see that $A \rightarrow B'$ is unramified at \mathfrak{q} . Hence we may apply Algebra, Proposition 10.144.8 to see that a principal localization of B' is a quotient of a standard étale A -algebra. \square

Via standard lifting arguments, one then obtains the following geometric statement which will be of essential use to us.

Theorem 40.12.3. *Let $\varphi : X \rightarrow Y$ be a morphism of schemes. Let $x \in X$. If φ is étale at x , then there exist affine opens $V \subset Y$ and $U \subset X$ with $x \in U$ and $\varphi(U) \subset V$ such that we have the following diagram*

$$\begin{array}{ccccc} X & \longleftarrow & U & \xrightarrow{j} & \text{Spec}(R[t]_{f'}/(f)) \\ \downarrow & & \downarrow & & \downarrow \\ Y & \longleftarrow & V & \xlongequal{\quad} & \text{Spec}(R) \end{array}$$

where j is an open immersion, and $f \in R[t]$ is monic.

Proof. This is equivalent to Morphisms, Lemma 28.37.14 although the statements differ slightly. \square

40.13. Étale and smooth morphisms

An étale morphism is smooth of relative dimension zero. The projection $\mathbf{A}_S^n \rightarrow S$ is a standard example of a smooth morphism of relative dimension n . It turns out that any smooth morphism is étale locally of this form. Here is the precise statement.

Theorem 40.13.1. *Let $\varphi : X \rightarrow Y$ be a morphism of schemes. Let $x \in X$. If φ is smooth at x , then there exist an integer $n \geq 0$ and affine opens $V \subset Y$ and $U \subset X$ with $x \in U$ and $\varphi(U) \subset V$ such that there exists a commutative diagram*

$$\begin{array}{ccccc}
 X & \longleftarrow & U & \xrightarrow{\pi} & \mathbf{A}_R^n & \xlongequal{\quad} & \text{Spec}(R[x_1, \dots, x_n]) \\
 \downarrow & & \downarrow & & \downarrow & & \swarrow \\
 Y & \longleftarrow & V & \xlongequal{\quad} & \text{Spec}(R) & &
 \end{array}$$

where π is étale.

Proof. See Morphisms, Lemma 28.37.20. □

40.14. Topological properties of étale morphisms

We present a few of the topological properties of étale and unramified morphisms. First, we give what Grothendieck calls the *fundamental property of étale morphisms*, see [Gro71, Exposé I.5].

Theorem 40.14.1. *Let $f : X \rightarrow Y$ be a morphism of schemes. The following are equivalent:*

- (1) f is an open immersion,
- (2) f is universally injective and étale, and
- (3) f is a flat monomorphism, locally of finite presentation.

Proof. An open immersion is universally injective since any base change of an open immersion is an open immersion. Moreover, it is étale by Morphisms, Lemma 28.37.9. Hence (1) implies (2).

Assume f is universally injective and étale. Since f is étale it is flat and locally of finite presentation, see Morphisms, Lemmas 28.37.12 and 28.37.11. By Lemma 40.7.1 we see that f is a monomorphism. Hence (2) implies (3).

Assume f is flat, locally of finite presentation, and a monomorphism. Then f is open, see Morphisms, Lemma 28.26.9. Thus we may replace Y by $f(X)$ and we may assume f is surjective. Then f is open and bijective hence a homeomorphism. Hence f is quasi-compact. Hence Descent, Lemma 34.21.1 shows that f is an isomorphism and we win. □

Here is another result of a similar flavor.

Lemma 40.14.2. *Let $\pi : X \rightarrow S$ be a morphism of schemes. Let $s \in S$. Assume that*

- (1) π is finite,
- (2) π is étale,
- (3) $\pi^{-1}(\{s\}) = \{x\}$, and

(4) $\kappa(s) \subset \kappa(x)$ is purely inseparable².

Then there exists an open neighbourhood U of s such that $\pi|_{\pi^{-1}(U)} : \pi^{-1}(U) \rightarrow U$ is an isomorphism.

Proof. By Lemma 40.7.3 there exists an open neighbourhood U of s such that $\pi|_{\pi^{-1}(U)} : \pi^{-1}(U) \rightarrow U$ is a closed immersion. But a morphism which is étale and a closed immersion is an open immersion (for example by Theorem 40.14.1). Hence after shrinking U we obtain an isomorphism. \square

40.15. Topological invariance of the étale topology

Next, we present an extremely crucial theorem which, roughly speaking, says that étaleness is a topological property.

Theorem 40.15.1. *Let X and Y be two schemes over a base scheme S . Let S_0 be a closed subscheme of S whose ideal sheaf has square zero. Denote X_0 (resp. Y_0) the base change $S_0 \times_S X$ (resp. $S_0 \times_S Y$). If X is étale over S , then the map*

$$\mathrm{Mor}_S(Y, X) \longrightarrow \mathrm{Mor}_{S_0}(Y_0, X_0)$$

is bijective.

Proof. After base changing via $Y \rightarrow S$, we may assume that $Y = S$. In this case the theorem states that any S -morphism $\sigma_0 : S_0 \rightarrow X$ actually factors uniquely through a section $S \rightarrow X$ of the étale structure morphism $X \rightarrow S$.

Existence. Since we have equality of underlying topological spaces $|S_0| = |S|$ and $|X_0| = |X|$, by Theorem 40.6.2, the section σ_0 is uniquely determined by a connected component X' of X such that the base change $X'_0 = S_0 \times_S X'$ maps isomorphically to S_0 . In particular, $X' \rightarrow S$ is a universal homeomorphism and therefore universally injective. Since $X' \rightarrow S$ is étale, it follows from Theorem 40.14.1 that $X' \rightarrow S$ is an isomorphism and, therefore, it has an inverse σ which is the required section.

Uniqueness. This follows from Theorem 40.5.1, or directly from Theorem 40.6.2, or, if one carefully observes, from our proof itself. \square

From the proof of preceding theorem, we also obtain one direction of the promised functorial characterization of étale morphisms. The following theorem will be strengthened in Étale Cohomology, Theorem 44.46.1.

Theorem 40.15.2 (Une équivalence remarquable de catégories). *Let S be a scheme. Let $S_0 \subset S$ be a closed subscheme defined by an ideal with square zero. The functor*

$$X \longmapsto X_0 = S_0 \times_S X$$

defines an equivalence of categories

$$\{\text{schemes } X \text{ étale over } S\} \leftrightarrow \{\text{schemes } X_0 \text{ étale over } S_0\}$$

Proof. By Theorem 40.15.1 we see that this functor is fully faithful. It remains to show that the functor is essentially surjective. Let $Y \rightarrow S_0$ be an étale morphism of schemes.

Suppose that the result holds if S and Y are affine. In that case, we choose an affine open covering $Y = \bigcup V_j$ such that each V_j maps into an affine open of S . By assumption (affine case) we can find étale morphisms $W_j \rightarrow S$ such that $W_{j,0} \cong V_j$

²In view of condition (2) this is equivalent to $\kappa(s) = \kappa(x)$.

(as schemes over S_0). Let $W_{j,j'} \subset W_j$ be the open subscheme whose underlying topological space corresponds to $V_j \cap V_{j'}$. Because we have isomorphisms

$$W_{j,j',0} \cong V_j \cap V_{j'} \cong W_{j',j,0}$$

as schemes over S_0 we see by fully faithfulness that we obtain isomorphisms $\theta_{j,j'} : W_{j,j'} \rightarrow W_{j',j}$ of schemes over S . We omit the verification that these isomorphisms satisfy the cocycle condition of Schemes, Section 25.14. Applying Schemes, Lemma 25.14.2 we obtain a scheme $X \rightarrow S$ by glueing the schemes W_j along the identifications $\theta_{j,j'}$. It is clear that $X \rightarrow S$ is étale and $X_0 \cong Y$ by construction.

Thus it suffices to show the lemma in case S and Y are affine. Say $S = \text{Spec}(R)$ and $S_0 = \text{Spec}(R/I)$ with $I^2 = 0$. By Algebra, Lemma 10.138.2 we know that Y is the spectrum of a ring \bar{A} with

$$\bar{A} = (R/I)[x_1, \dots, x_n]/(\bar{f}_1, \dots, \bar{f}_n)$$

such that

$$\bar{g} = \det \begin{pmatrix} \partial \bar{f}_1 / \partial x_1 & \partial \bar{f}_2 / \partial x_1 & \dots & \partial \bar{f}_n / \partial x_1 \\ \partial \bar{f}_1 / \partial x_2 & \partial \bar{f}_2 / \partial x_2 & \dots & \partial \bar{f}_n / \partial x_2 \\ \dots & \dots & \dots & \dots \\ \partial \bar{f}_1 / \partial x_n & \partial \bar{f}_2 / \partial x_n & \dots & \partial \bar{f}_n / \partial x_n \end{pmatrix}$$

maps to an invertible element in A . Choose any lifts $f_i \in R[x_1, \dots, x_n]$. Since I is nilpotent it follows that the determinant of the matrix of partials of the f_i is invertible in the algebra A defined by

$$A = R[x_1, \dots, x_n]/(f_1, \dots, f_n)$$

Hence $R \rightarrow A$ is étale and $(R/I) \otimes_R A \cong \bar{A}$. To prove the general case one argues with glueing affine pieces. □

40.16. The functorial characterization

We finally present the promised functorial characterization. Thus there are four ways to think about étale morphisms of schemes:

- (1) as a smooth morphism of relative dimension 0,
- (2) as locally finitely presented, flat, and unramified morphisms,
- (3) using the structure theorem, and
- (4) using the functorial characterization.

Theorem 40.16.1. *Let $f : X \rightarrow S$ be a morphism that is locally of finite presentation. The following are equivalent*

- (1) f is étale,
- (2) for all affine S -schemes Y , and closed subschemes $Y_0 \subset Y$ defined by square-zero ideals, the natural map

$$\text{Mor}_S(Y, X) \longrightarrow \text{Mor}_S(Y_0, X)$$

is bijective.

Proof. This is More on Morphisms, Lemma 36.6.9. □

This characterization says that solutions to the equations defining X can be lifted uniquely through nilpotent thickenings.

40.17. Étale local structure of unramified morphisms

In the chapter More on Morphisms, Section 36.30 the reader can find some results on the étale local structure of quasi-finite morphisms. In this section we want to combine this with the topological properties of unramified morphisms we have seen in this chapter. The basic overall picture to keep in mind is

$$\begin{array}{ccccc} V & \longrightarrow & X_U & \longrightarrow & X \\ & \searrow & \downarrow & & \downarrow f \\ & & U & \longrightarrow & S \end{array}$$

see More on Morphisms, Equation (36.30.0.1). We start with a very general case.

Lemma 40.17.1. *Let $f : X \rightarrow S$ be a morphism of schemes. Let $x_1, \dots, x_n \in X$ be points having the same image s in S . Assume f is unramified at each x_i . Then there exists an étale neighbourhood $(U, u) \rightarrow (S, s)$ and opens $V_{i,j} \subset X_U$, $i = 1, \dots, n$, $j = 1, \dots, m_i$ such that*

- (1) $V_{i,j} \rightarrow U$ is a closed immersion passing through u ,
- (2) u is not in the image of $V_{i,j} \cap V_{i',j'}$ unless $i = i'$ and $j = j'$, and
- (3) any point of $(X_U)_u$ mapping to x_i is in some $V_{i,j}$.

Proof. By Morphisms, Definition 28.36.1 there exists an open neighbourhood of each x_i which is locally of finite type over S . Replacing X by an open neighbourhood of $\{x_1, \dots, x_n\}$ we may assume f is locally of finite type. Apply More on Morphisms, Lemma 36.30.3 to get the étale neighbourhood (U, u) and the opens $V_{i,j}$ finite over U . By Lemma 40.7.3 after possibly shrinking U we get that $V_{i,j} \rightarrow U$ is a closed immersion. \square

Lemma 40.17.2. *Let $f : X \rightarrow S$ be a morphism of schemes. Let $x_1, \dots, x_n \in X$ be points having the same image s in S . Assume f is separated and f is unramified at each x_i . Then there exists an étale neighbourhood $(U, u) \rightarrow (S, s)$ and a disjoint union decomposition*

$$X_U = W \amalg \coprod_{i,j} V_{i,j}$$

such that

- (1) $V_{i,j} \rightarrow U$ is a closed immersion passing through u ,
- (2) the fibre W_u contains no point mapping to any x_i .

In particular, if $f^{-1}(\{s\}) = \{x_1, \dots, x_n\}$, then the fibre W_u is empty.

Proof. Apply Lemma 40.17.1. We may assume U is affine, so X_U is separated. Then $V_{i,j} \rightarrow X_U$ is a closed map, see Morphisms, Lemma 28.42.7. Suppose $(i, j) \neq (i', j')$. Then $V_{i,j} \cap V_{i',j'}$ is closed in $V_{i,j}$ and its image in U does not contain u . Hence after shrinking U we may assume that $V_{i,j} \cap V_{i',j'} = \emptyset$. Moreover, $\bigcup V_{i,j}$ is a closed and open subscheme of X_U and hence has an open and closed complement W . This finishes the proof. \square

The following lemma is in some sense much weaker than the preceding one but it may be useful to state it explicitly here. It says that a finite unramified morphism is étale locally on the base a closed immersion.

Lemma 40.17.3. *Let $f : X \rightarrow S$ be a finite unramified morphism of schemes. Let $s \in S$. There exists an étale neighbourhood $(U, u) \rightarrow (S, s)$ and a disjoint union decomposition*

$$X_U = \coprod_j V_j$$

such that each $V_j \rightarrow U$ is a closed immersion.

Proof. Since $X \rightarrow S$ is finite the fibre over S is a finite set $\{x_1, \dots, x_n\}$ of points of X . Apply Lemma 40.17.2 to this set (a finite morphism is separated, see Morphisms, Section 28.44). The image of W in U is a closed subset (as $X_U \rightarrow U$ is finite, hence proper) which does not contain u . After removing this from U we see that $W = \emptyset$ as desired. \square

40.18. Étale local structure of étale morphisms

This is a bit silly, but perhaps helps form intuition about étale morphisms. We simply copy over the results of Section 40.17 and change “closed immersion” into “isomorphism”.

Lemma 40.18.1. *Let $f : X \rightarrow S$ be a morphism of schemes. Let $x_1, \dots, x_n \in X$ be points having the same image s in S . Assume f is étale at each x_i . Then there exists an étale neighbourhood $(U, u) \rightarrow (S, s)$ and opens $V_{i,j} \subset X_U$, $i = 1, \dots, n$, $j = 1, \dots, m_i$ such that*

- (1) $V_{i,j} \rightarrow U$ is an isomorphism,
- (2) u is not in the image of $V_{i,j} \cap V_{i',j'}$ unless $i = i'$ and $j = j'$, and
- (3) any point of $(X_U)_u$ mapping to x_i is in some $V_{i,j}$.

Proof. An étale morphism is unramified, hence we may apply Lemma 40.17.1. Now $V_{i,j} \rightarrow U$ is a closed immersion and étale. Hence it is an open immersion, for example by Theorem 40.14.1. Replace U by the intersection of the images of $V_{i,j} \rightarrow U$ to get the lemma. \square

Lemma 40.18.2. *Let $f : X \rightarrow S$ be a morphism of schemes. Let $x_1, \dots, x_n \in X$ be points having the same image s in S . Assume f is separated and f is étale at each x_i . Then there exists an étale neighbourhood $(U, u) \rightarrow (S, s)$ and a disjoint union decomposition*

$$X_U = W \amalg \coprod_{i,j} V_{i,j}$$

such that

- (1) $V_{i,j} \rightarrow U$ is an isomorphism,
- (2) the fibre W_u contains no point mapping to any x_i .

In particular, if $f^{-1}(\{s\}) = \{x_1, \dots, x_n\}$, then the fibre W_u is empty.

Proof. An étale morphism is unramified, hence we may apply Lemma 40.17.2. As in the proof of Lemma 40.18.1 the morphisms $V_{i,j} \rightarrow U$ are open immersions and we win after replacing U by the intersection of their images. \square

The following lemma is in some sense much weaker than the preceding one but it may be useful to state it explicitly here. It says that a finite étale morphism is étale locally on the base a “topological covering space”, i.e., a finite product of copies of the base.

Lemma 40.18.3. *Let $f : X \rightarrow S$ be a finite étale morphism of schemes. Let $s \in S$. There exists an étale neighbourhood $(U, u) \rightarrow (S, s)$ and a disjoint union decomposition*

$$X_U = \coprod_j V_j$$

such that each $V_j \rightarrow U$ is an isomorphism.

Proof. An étale morphism is unramified, hence we may apply Lemma 40.17.3. As in the proof of Lemma 40.18.1 we see that $V_{i,j} \rightarrow U$ is an open immersion and we win after replacing U by the intersection of their images. \square

40.19. Permanence properties

In what follows, we present a few “permanence” properties of étale homomorphisms of Noetherian local rings (as defined in Definition 40.11.1). See More on Algebra, Sections 15.32 and 15.34 for the analogue of this material for the completion and henselization of a Noetherian local ring.

Lemma 40.19.1. *Let A, B be Noetherian local rings. Let $A \rightarrow B$ be a étale homomorphism of local rings. Then $\dim(A) = \dim(B)$.*

Proof. See for example Algebra, Lemma 10.108.7. \square

Proposition 40.19.2. *Let A, B be Noetherian local rings. Let $f : A \rightarrow B$ be an étale homomorphism of local rings. Then $\text{depth}(A) = \text{depth}(B)$*

Proof. See Algebra, Lemma 10.151.2. \square

Proposition 40.19.3. *Let A, B be Noetherian local rings. Let $f : A \rightarrow B$ be an étale homomorphism of local rings. Then A is Cohen-Macaulay if and only if B is so.*

Proof. A local ring A is Cohen-Macaulay if and only $\dim(A) = \text{depth}(A)$. As both of these invariants is preserved under an étale extension, the claim follows. \square

Proposition 40.19.4. *Let A, B be Noetherian local rings. Let $f : A \rightarrow B$ be an étale homomorphism of local rings. Then A is regular if and only if B is so.*

Proof. If B is regular, then A is regular by Algebra, Lemma 10.106.9. Assume A is regular. Let \mathfrak{m} be the maximal ideal of A . Then $\dim_{\kappa(\mathfrak{m})} \mathfrak{m}/\mathfrak{m}^2 = \dim(A) = \dim(B)$ (see Lemma 40.19.1). On the other hand, $\mathfrak{m}B$ is the maximal ideal of B and hence $\mathfrak{m}_B/\mathfrak{m}_B = \mathfrak{m}B/\mathfrak{m}^2B$ is generated by at most $\dim(B)$ elements. Thus B is regular. (You can also use the slightly more general Algebra, Lemma 10.108.8.) \square

Proposition 40.19.5. *Let A, B be Noetherian local rings. Let $f : A \rightarrow B$ be an étale homomorphism of local rings. Then A is reduced if and only if B is so.*

Proof. It is clear from the faithful flatness of $A \rightarrow B$ that if B is reduced, so is A . See also Algebra, Lemma 10.152.2. Conversely, assume A is reduced. By assumption B is a localization of a finite type A -algebra B' at some prime \mathfrak{q} . After replacing B' by a localization we may assume that B' is étale over A , see Lemma 40.11.2. Then we see that Algebra, Lemma 10.151.6 applies to $A \rightarrow B'$ and B' is reduced. Hence B is reduced. \square

Remark 40.19.6. The result on “reducedness” does not hold with a weaker definition of étale local ring maps $A \rightarrow B$ where one drops the assumption that B is essentially of finite type over A . Namely, it can happen that a Noetherian local domain A has nonreduced completion A^\wedge , see Examples, Section 82.15. But the ring map $A \rightarrow A^\wedge$ is flat, and $\mathfrak{m}_A A^\wedge$ is the maximal ideal of A^\wedge and of course A and A^\wedge have the same residue fields. This is why it is important to consider this notion only for ring extensions which are essentially of finite type (or essentially of finite presentation if A is not Noetherian).

Proposition 40.19.7. *Let A, B be Noetherian local rings. Let $f : A \rightarrow B$ be an étale homomorphism of local rings. Then A is a normal domain if and only if B is so.*

Proof. See Algebra, Lemma 10.152.3 for descending normality. Conversely, assume A is normal. By assumption B is a localization of a finite type A -algebra B' at some prime \mathfrak{q} . After replacing B' by a localization we may assume that B' is étale over A , see Lemma 40.11.2. Then we see that Algebra, Lemma 10.151.7 applies to $A \rightarrow B'$ and we conclude that B' is normal. Hence B is a normal domain. \square

The preceding propositions give some indication as to why we’d like to think of étale maps as “local isomorphisms”. Another property that gives an excellent indication that we have the “right” definition is the fact that for \mathbf{C} -schemes of finite type, a morphism is étale if and only if the associated morphism on analytic spaces (the \mathbf{C} -valued points given the complex topology) is a local isomorphism in the analytic sense (open embedding locally on the source). This fact can be proven with the aid of the structure theorem and the fact that the analytification commutes with the formation of the completed local rings – the details are left to the reader.

Chow Homology and Chern Classes

41.1. Introduction

In this chapter we discuss Chow homology groups and the construction of chern classes of vector bundles as elements of operational Chow cohomology groups (everything with \mathbf{Z} -coefficients). We follow the first few chapters of [Ful98], except that we have been less precise about the supports of the cycles involved. More classical discussions of Chow groups can be found in [Sam56], [Che58a], and [Che58b]. Of course there are many others.

To make the material a little bit more challenging we decided to treat a somewhat more general case than is usually done. Namely we assume our schemes X are locally of finite type over a fixed locally Noetherian base scheme which is universally catenary and has a given dimension function. This seems to be all that is needed to be able to define the Chow homology groups $A_*(X)$ and the action of capping with chern classes on them. This is an indication that we should be able to define these also for algebraic stacks locally of finite type over such a base.

In another chapter we will define the intersection products on $A_*(X)$ using Serre's Tor-formula in case X is nonsingular (see [Ser00], or [Ser65]) and we have a good moving lemma. See (insert future reference here).

41.2. Determinants of finite length modules

The material in this section is related to the material in the paper [KM76] and to the material in the thesis [Ros09]. If you have a good reference then please email stacks.project@gmail.com.

Given any field κ and any finite dimensional κ -vector space V we set $\det_\kappa(V) = \wedge^n(V)$ where $n = \dim_\kappa(V)$. We want to generalize this slightly.

Definition 41.2.1. Let R be a local ring with maximal ideal \mathfrak{m} and residue field κ . Let M be a finite length R -module. Say $l = \text{length}_R(M)$.

- (1) Given elements $x_1, \dots, x_r \in M$ we denote $\langle x_1, \dots, x_r \rangle = Rx_1 + \dots + Rx_r$ the R -submodule of M generated by x_1, \dots, x_r .
- (2) We will say an l -tuple of elements (e_1, \dots, e_l) of M is *admissible* if $\mathfrak{m}e_i \in \langle e_1, \dots, e_{i-1} \rangle$ for $i = 1, \dots, l$.
- (3) A *symbol* $[e_1, \dots, e_l]$ will mean (e_1, \dots, e_l) is an admissible l -tuple.
- (4) An *admissible relation* between symbols is one of the following:
 - (a) if (e_1, \dots, e_l) is an admissible sequence and for some $1 \leq a \leq l$ we have $e_a \in \langle e_1, \dots, e_{a-1} \rangle$, then $[e_1, \dots, e_l] = 0$,

- (b) if (e_1, \dots, e_l) is an admissible sequence and for some $1 \leq a \leq l$ we have $e_a = \lambda e'_a + x$ with $\lambda \in R^*$, and $x \in \langle e_1, \dots, e_{a-1} \rangle$, then

$$[e_1, \dots, e_l] = \bar{\lambda}[e_1, \dots, e_{a-1}, e'_a, e_{a+1}, \dots, e_l]$$

where $\bar{\lambda} \in \kappa^*$ is the image of λ in the residue field, and

- (c) if (e_1, \dots, e_l) is an admissible sequence and $\mathfrak{m}e_a \subset \langle e_1, \dots, e_{a-2} \rangle$ then

$$[e_1, \dots, e_l] = -[e_1, \dots, e_{a-2}, e_a, e_{a-1}, e_{a+1}, \dots, e_l].$$

- (5) We define the *determinant of the finite length R -module M* to be

$$\det_{\kappa}(M) = \left\{ \frac{\kappa\text{-vector space generated by symbols}}{\kappa\text{-linear combinations of admissible relations}} \right\}$$

We stress that always $l = \text{length}_R(M)$. We also stress that it does not follow that the symbol $[e_1, \dots, e_l]$ is additive in the entries (this will typically not be the case). Before we can show that the determinant $\det_{\kappa}(M)$ actually has dimension 1 we have to show that it has dimension at most 1.

Lemma 41.2.2. *With notations as above we have $\dim_{\kappa}(\det_{\kappa}(M)) \leq 1$.*

Proof. Fix an admissible sequence (f_1, \dots, f_l) of M such that

$$\text{length}_R(\langle f_1, \dots, f_i \rangle) = i$$

for $i = 1, \dots, l$. Such an admissible sequence exists exactly because M has length l . We will show that any element of $\det_{\kappa}(M)$ is a κ -multiple of the symbol $[f_1, \dots, f_l]$. This will prove the lemma.

Let (e_1, \dots, e_l) be an admissible sequence of M . It suffices to show that $[e_1, \dots, e_l]$ is a multiple of $[f_1, \dots, f_l]$. First assume that $\langle e_1, \dots, e_l \rangle \neq M$. Then there exists an $i \in [1, \dots, l]$ such that $e_i \in \langle e_1, \dots, e_{i-1} \rangle$. It immediately follows from the first admissible relation that $[e_1, \dots, e_n] = 0$ in $\det_{\kappa}(M)$. Hence we may assume that $\langle e_1, \dots, e_l \rangle = M$. In particular there exists a smallest index $i \in \{1, \dots, l\}$ such that $f_1 \in \langle e_1, \dots, e_i \rangle$. This means that $e_i = \lambda f_1 + x$ with $x \in \langle e_1, \dots, e_{i-1} \rangle$ and $\lambda \in R^*$. By the second admissible relation this means that $[e_1, \dots, e_i] = \bar{\lambda}[e_1, \dots, e_{i-1}, f_1, e_{i+1}, \dots, e_l]$. Note that $\mathfrak{m}f_1 = 0$. Hence by applying the third admissible relation $i - 1$ times we see that

$$[e_1, \dots, e_l] = (-1)^{i-1} \bar{\lambda} [f_1, e_1, \dots, e_{i-1}, e_{i+1}, \dots, e_l].$$

Note that it is also the case that $\langle f_1, e_1, \dots, e_{i-1}, e_{i+1}, \dots, e_l \rangle = M$. By induction suppose we have proven that our original symbol is equal to a scalar times

$$[f_1, \dots, f_j, e_{j+1}, \dots, e_l]$$

for some admissible sequence $(f_1, \dots, f_j, e_{j+1}, \dots, e_l)$ whose elements generate M , i.e., with $\langle f_1, \dots, f_j, e_{j+1}, \dots, e_l \rangle = M$. Then we find the smallest i such that $f_{j+1} \in \langle f_1, \dots, f_j, e_{j+1}, \dots, e_i \rangle$ and we go through the same process as above to see that

$$[f_1, \dots, f_j, e_{j+1}, \dots, e_l] = (\text{scalar})[f_1, \dots, f_j, f_{j+1}, e_{j+1}, \dots, \hat{e}_i, \dots, e_l]$$

Continuing in this vein we obtain the desired result. \square

Before we show that $\det_{\kappa}(M)$ always has dimension 1, let us show that it agrees with the usual top exterior power in the case the module is a vector space over κ .

Lemma 41.2.3. *Let R be a local ring with maximal ideal \mathfrak{m} and residue field κ . Let M be a finite length R -module which is annihilated by \mathfrak{m} . Let $l = n = \dim_{\kappa}(M)$. Then the map*

$$\det_{\kappa}(M) \longrightarrow \wedge_{\kappa}^l(M), \quad [e_1, \dots, e_l] \longmapsto e_1 \wedge \dots \wedge e_l$$

is an isomorphism.

Proof. It is clear that the rule described in the lemma gives a κ -linear map since all of the admissible relations are satisfied by the usual symbols $e_1 \wedge \dots \wedge e_l$. It is also clearly a surjective map. Since by Lemma 41.2.2 the left hand side has dimension at most one we see that the map is an isomorphism. \square

Lemma 41.2.4. *Let R be a local ring with maximal ideal \mathfrak{m} and residue field κ . Let M be a finite length R -module. The determinant $\det_{\kappa}(M)$ defined above is a κ -vector space of dimension 1. It is generated by the symbol $[f_1, \dots, f_l]$ for any admissible sequence such that $\langle f_1, \dots, f_l \rangle = M$.*

Proof. We know $\det_{\kappa}(M)$ has dimension at most 1, and in fact that it is generated by $[f_1, \dots, f_l]$, by Lemma 41.2.2 and its proof. We will show by induction on $l = \text{length}(M)$ that it is nonzero. For $l = 1$ it follows from Lemma 41.2.3. Choose a nonzero element $f \in M$ with $\mathfrak{m}f = 0$. Set $\overline{M} = M/\langle f \rangle$, and denote the quotient map $x \mapsto \overline{x}$. We will define a surjective map

$$\psi : \det_{\kappa}(M) \rightarrow \det_{\kappa}(\overline{M})$$

which will prove the lemma since by induction the determinant of \overline{M} is nonzero.

We define ψ on symbols as follows. Let (e_1, \dots, e_l) be an admissible sequence. If $f \notin \langle e_1, \dots, e_l \rangle$ then we simply set $\psi([e_1, \dots, e_l]) = 0$. If $f \in \langle e_1, \dots, e_l \rangle$ then we choose an i minimal such that $f \in \langle e_1, \dots, e_i \rangle$ and write $e_i = \lambda f + x$ for some $\lambda \in R$ and $x \in \langle e_1, \dots, e_{i-1} \rangle$. In this case we set

$$\psi([e_1, \dots, e_l]) = \overline{\lambda}[\overline{e}_1, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_l].$$

Note that it is indeed the case that $(\overline{e}_1, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_l)$ is an admissible sequence in \overline{M} , so this makes sense. Let us show that extending this rule κ -linearly to linear combinations of symbols does indeed lead to a map on determinants. To do this we have to show that the admissible relations are mapped to zero.

Type (a) relations. Suppose we have (e_1, \dots, e_l) an admissible sequence and for some $1 \leq a \leq l$ we have $e_a \in \langle e_1, \dots, e_{a-1} \rangle$. Suppose that $f \in \langle e_1, \dots, e_i \rangle$ with i minimal. Then it is immediate that $i \neq a$. Since it is also the case that $\overline{e}_a \in \langle \overline{e}_1, \dots, \overline{e}_i, \dots, \overline{e}_{a-1} \rangle$ we see immediately that the same admissible relation for $\det_{\kappa}(\overline{M})$ forces the symbol $[\overline{e}_1, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_l]$ to be zero as desired.

Type (b) relations. Suppose we have (e_1, \dots, e_l) an admissible sequence and for some $1 \leq a \leq l$ we have $e_a = \lambda e'_a + x$ with $\lambda \in R^*$, and $x \in \langle e_1, \dots, e_{a-1} \rangle$. Suppose that $f \in \langle e_1, \dots, e_i \rangle$ with i minimal. Say $e_i = \mu f + y$ with $y \in \langle e_1, \dots, e_{i-1} \rangle$. If $i < a$ then the desired equality is

$$\overline{\lambda}[\overline{e}_1, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_l] = \overline{\lambda}[\overline{e}_1, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_{a-1}, \overline{e}'_a, \overline{e}_{a+1}, \dots, \overline{e}_l]$$

which follows from $\overline{e}_a = \lambda \overline{e}'_a + \overline{x}$ and the corresponding admissible relation for $\det_{\kappa}(\overline{M})$. If $i > a$ then the desired equality is

$$\overline{\lambda}[\overline{e}_1, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_l] = \overline{\lambda}[\overline{e}_1, \dots, \overline{e}_{a-1}, \overline{e}'_a, \overline{e}_{a+1}, \dots, \overline{e}_{i-1}, \overline{e}_{i+1}, \dots, \overline{e}_l]$$

which follows from $\bar{e}_a = \lambda e'_a + \bar{x}$ and the corresponding admissible relation for $\det_\kappa(\bar{M})$. The interesting case is when $i = a$. In this case we have $e_a = \lambda e'_a + x = \mu f + y$. Hence also $e'_a = \lambda^{-1}(\mu f + y - x)$. Thus we see that

$$\psi([e_1, \dots, e_l]) = \bar{\mu}[\bar{e}_1, \dots, \bar{e}_{i-1}, \bar{e}_{i+1}, \dots, \bar{e}_l] = \psi(\bar{\lambda}[e_1, \dots, e_{a-1}, e'_a, e_{a+1}, \dots, e_l])$$

as desired.

Type (c) relations. Suppose that (e_1, \dots, e_l) is an admissible sequence and $\mathfrak{m}_{e_a} \subset \langle e_1, \dots, e_{a-2} \rangle$. Suppose that $f \in \langle e_1, \dots, e_i \rangle$ with i minimal. Say $e_i = \lambda f + x$ with $x \in \langle e_1, \dots, e_{i-1} \rangle$. If $i < a - 1$, then the desired equality is

$$\bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{i-1}, \bar{e}_{i+1}, \dots, \bar{e}_l] = \bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{i-1}, \bar{e}_{i+1}, \dots, \bar{e}_{a-2}, \bar{e}_a, \bar{e}_{a-1}, \bar{e}_{a+1}, \dots, \bar{e}_l]$$

which follows from the type (c) admissible relation for $\det_\kappa(\bar{M})$. Similarly, if $i > a$, then the desired equality is

$$\bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{i-1}, \bar{e}_{i+1}, \dots, \bar{e}_l] = \bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{a-2}, \bar{e}_a, \bar{e}_{a-1}, \bar{e}_{a+1}, \dots, \bar{e}_{i-1}, \bar{e}_{i+1}, \dots, \bar{e}_l]$$

which follows from the type (c) admissible relation for $\det_\kappa(\bar{M})$. If $i = a$, then the desired equality is

$$\bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{a-1}, \bar{e}_{a+1}, \dots, \bar{e}_l] = \bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{a-2}, \bar{e}_{a-1}, \bar{e}_{a+1}, \dots, \bar{e}_l]$$

which is tautological. Finally, the interesting case is $i = a - 1$. This case itself splits into two cases as to whether $f \in \langle e_1, \dots, e_{a-2}, e_a \rangle$ or not. If not, then we see that the desired equality is

$$\bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{a-2}, \bar{e}_a, \dots, \bar{e}_l] = \bar{\lambda}[\bar{e}_1, \dots, \bar{e}_{a-2}, \bar{e}_a, \bar{e}_{a+1}, \dots, \bar{e}_l]$$

which is tautological since after switching e_{a-1} and e_a the smallest index such that f is in the becomes equal to $i' = a$ and it is again e_a which is removed. On the other hand, suppose that $f \in \langle e_1, \dots, e_{a-2}, e_a \rangle$. In this case we see that we can, besides the equality $e_{a-1} = \lambda f + x$ of above, also write $e_a = \mu f + y$ with $y \in \langle e_1, \dots, e_{a-2} \rangle$. Clearly this means that both $e_a \in \langle e_1, \dots, e_{a-1} \rangle$ and $e_{a-1} \in \langle e_1, \dots, e_{a-2}, e_a \rangle$. Thus we can use relations of type (a) and the compatibility of ψ with these shown above to see that both

$$\psi([e_1, \dots, e_l]) \quad \text{and} \quad \psi([e_1, \dots, e_{a-2}, e_a, e_{a-1}, e_{a+1}, \dots, e_l])$$

are zero, as desired.

At this point we have shown that ψ is well defined, and all that remains is to show that it is surjective. To see this let $(\bar{f}_2, \dots, \bar{f}_l)$ be an admissible sequence in \bar{M} . We can choose lifts $f_2, \dots, f_l \in M$, and then (f, f_2, \dots, f_l) is an admissible sequence in M . Since $\psi([f, f_2, \dots, f_l]) = [f_2, \dots, f_l]$ we win. \square

Let R be a local ring with maximal ideal \mathfrak{m} and residue field κ . Note that if $\varphi : M \rightarrow N$ is an isomorphism of finite length R -modules, then we get an isomorphism

$$\det_\kappa(\varphi) : \det_\kappa(M) \rightarrow \det_\kappa(N)$$

simply by the rule

$$\det_\kappa(\varphi)([e_1, \dots, e_l]) = [\varphi(e_1), \dots, \varphi(e_l)]$$

for any symbol $[e_1, \dots, e_l]$ for M . Hence we see that \det_κ is a functor

$$(41.2.4.1) \quad \left\{ \begin{array}{l} \text{finite length } R\text{-modules} \\ \text{with isomorphisms} \end{array} \right\} \longrightarrow \left\{ \begin{array}{l} \text{1-dimensional } \kappa\text{-vector spaces} \\ \text{with isomorphisms} \end{array} \right\}$$

This is typical for a “determinant functor” (see [Knu02]), as is the following additivity property.

Lemma 41.2.5. *Let $(R, \mathfrak{m}, \kappa)$ be a local ring. For every short exact sequence*

$$0 \rightarrow K \rightarrow L \rightarrow M \rightarrow 0$$

of finite length R -modules there exists a canonical isomorphism

$$\gamma_{K \rightarrow L \rightarrow M} : \det_{\kappa}(K) \otimes_{\kappa} \det_{\kappa}(M) \longrightarrow \det_{\kappa}(L)$$

defined by the rule on nonzero symbols

$$[e_1, \dots, e_k] \otimes [\bar{f}_1, \dots, \bar{f}_m] \longrightarrow [e_1, \dots, e_k, f_1, \dots, f_m]$$

with the following properties:

- (1) *For every isomorphism of short exact sequences, i.e., for every commutative diagram*

$$\begin{array}{ccccccc} 0 & \longrightarrow & K & \longrightarrow & L & \longrightarrow & M \longrightarrow 0 \\ & & \downarrow u & & \downarrow v & & \downarrow w \\ 0 & \longrightarrow & K' & \longrightarrow & L' & \longrightarrow & M' \longrightarrow 0 \end{array}$$

with short exact rows and isomorphisms u, v, w we have

$$\gamma_{K' \rightarrow L' \rightarrow M'} \circ (\det_{\kappa}(u) \otimes \det_{\kappa}(w)) = \det_{\kappa}(v) \circ \gamma_{K \rightarrow L \rightarrow M},$$

- (2) *for every commutative square of finite length R -modules with exact rows and columns*

$$\begin{array}{ccccccc} & & 0 & & 0 & & 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & A & \longrightarrow & B & \longrightarrow & C \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & D & \longrightarrow & E & \longrightarrow & F \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & G & \longrightarrow & H & \longrightarrow & I \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ & & 0 & & 0 & & 0 \end{array}$$

the following diagram is commutative

$$\begin{array}{ccc} \det_{\kappa}(A) \otimes \det_{\kappa}(C) \otimes \det_{\kappa}(G) \otimes \det_{\kappa}(I) & \xrightarrow{\gamma_{A \rightarrow B \rightarrow C} \otimes \gamma_{G \rightarrow H \rightarrow I}} & \det_{\kappa}(B) \otimes \det_{\kappa}(H) \\ \downarrow \epsilon & & \downarrow \gamma_{B \rightarrow E \rightarrow H} \\ & & \det_{\kappa}(E) \\ & & \uparrow \gamma_{D \rightarrow E \rightarrow F} \\ \det_{\kappa}(A) \otimes \det_{\kappa}(G) \otimes \det_{\kappa}(C) \otimes \det_{\kappa}(I) & \xrightarrow{\gamma_{A \rightarrow D \rightarrow G} \otimes \gamma_{C \rightarrow F \rightarrow I}} & \det_{\kappa}(D) \otimes \det_{\kappa}(F) \end{array}$$

where ϵ is the switch of the factors in the tensor product times $(-1)^{cg}$ with $c = \text{length}_R(C)$ and $g = \text{length}_R(G)$, and

(3) *the map $\gamma_{K \rightarrow L \rightarrow M}$ agrees with the usual isomorphism if $0 \rightarrow K \rightarrow L \rightarrow M \rightarrow 0$ is actually a short exact sequence of κ -vector spaces.*

Proof. The significance of taking nonzero symbols in the explicit description of the map $\gamma_{K \rightarrow L \rightarrow M}$ is simply that if (e_1, \dots, e_l) is an admissible sequence in K , and $(\bar{f}_1, \dots, \bar{f}_m)$ is an admissible sequence in M , then it is not guaranteed that $(e_1, \dots, e_l, f_1, \dots, f_m)$ is an admissible sequence in L (where of course $f_i \in L$ signifies a lift of \bar{f}_i). However, if the symbol $[e_1, \dots, e_l]$ is nonzero in $\det_\kappa(K)$, then necessarily $K = \langle e_1, \dots, e_k \rangle$ (see proof of Lemma 41.2.2), and in this case it is true that $(e_1, \dots, e_k, f_1, \dots, f_m)$ is an admissible sequence. Moreover, by the admissible relations of type (b) for $\det_\kappa(L)$ we see that the value of $[e_1, \dots, e_k, f_1, \dots, f_m]$ in $\det_\kappa(L)$ is independent of the choice of the lifts f_i in this case also. Given this remark, it is clear that an admissible relation for e_1, \dots, e_k in K translates into an admissible relation among $e_1, \dots, e_k, f_1, \dots, f_m$ in L , and similarly for an admissible relation among the $\bar{f}_1, \dots, \bar{f}_m$. Thus γ defines a linear map of vector spaces as claimed in the lemma.

By Lemma 41.2.4 we know $\det_\kappa(L)$ is generated by any single symbol $[x_1, \dots, x_{k+m}]$ such that (x_1, \dots, x_{k+m}) is an admissible sequence with $L = \langle x_1, \dots, x_{k+m} \rangle$. Hence it is clear that the map $\gamma_{K \rightarrow L \rightarrow M}$ is surjective and hence an isomorphism.

Property (1) holds because

$$\begin{aligned} & \det_\kappa(v)([e_1, \dots, e_k, f_1, \dots, f_m]) \\ &= [v(e_1), \dots, v(e_k), v(f_1), \dots, v(f_m)] \\ &= \gamma_{K' \rightarrow L' \rightarrow M'}([u(e_1), \dots, u(e_k)] \otimes [w(f_1), \dots, w(f_m)]). \end{aligned}$$

Property (2) means that given a symbol $[\alpha_1, \dots, \alpha_a]$ generating $\det_\kappa(A)$, a symbol $[\gamma_1, \dots, \gamma_c]$ generating $\det_\kappa(C)$, a symbol $[\zeta_1, \dots, \zeta_g]$ generating $\det_\kappa(G)$, and a symbol $[\iota_1, \dots, \iota_i]$ generating $\det_\kappa(I)$ we have

$$\begin{aligned} & [\alpha_1, \dots, \alpha_a, \tilde{\gamma}_1, \dots, \tilde{\gamma}_c, \tilde{\zeta}_1, \dots, \tilde{\zeta}_g, \tilde{\iota}_1, \dots, \tilde{\iota}_i] \\ &= (-1)^{cg} [\alpha_1, \dots, \alpha_a, \tilde{\zeta}_1, \dots, \tilde{\zeta}_g, \tilde{\gamma}_1, \dots, \tilde{\gamma}_c, \tilde{\iota}_1, \dots, \tilde{\iota}_i] \end{aligned}$$

(for suitable lifts \tilde{x} in E) in $\det_\kappa(E)$. This holds because we may use the admissible relations of type (c) cg times in the following order: move the $\tilde{\zeta}_1$ past the elements $\tilde{\gamma}_c, \dots, \tilde{\gamma}_1$ (allowed since $\mathfrak{m}_{\tilde{\zeta}_1} \subset A$), then move $\tilde{\zeta}_2$ past the elements $\tilde{\gamma}_c, \dots, \tilde{\gamma}_1$ (allowed since $\mathfrak{m}_{\tilde{\zeta}_2} \subset A + R\tilde{\zeta}_1$), and so on.

Part (3) of the lemma is obvious. This finishes the proof. □

We can use the maps γ of the lemma to define more general maps γ as follows. Suppose that $(R, \mathfrak{m}, \kappa)$ is a local ring. Let M be a finite length R -module and suppose we are given a finite filtration (see Homology, Definition 12.16.1)

$$M = F^n \supset F^{n+1} \supset \dots \supset F^{m-1} \supset F^m = 0.$$

Then there is a canonical isomorphism

$$\gamma_{(M, F)} : \bigotimes_i \det_\kappa(F^i/F^{i+1}) \longrightarrow \det_\kappa(M)$$

well defined up to sign(!). One can make the sign explicit either by giving a well defined order of the terms in the tensor product (starting with higher indices unfortunately), and by thinking of the target category for the functor \det_κ as the category of 1-dimensional super vector spaces. See [KM76, Section 1].

Here is another typical result for determinant functors. It is not hard to show. The tricky part is usually to show the existence of a determinant functor.

Lemma 41.2.6. *Let $(R, \mathfrak{m}, \kappa)$ be any local ring. The functor*

$$\det_{\kappa} : \left\{ \begin{array}{l} \text{finite length } R\text{-modules} \\ \text{with isomorphisms} \end{array} \right\} \longrightarrow \left\{ \begin{array}{l} \text{1-dimensional } \kappa\text{-vector spaces} \\ \text{with isomorphisms} \end{array} \right\}$$

endowed with the maps $\gamma_{K \rightarrow L \rightarrow M}$ is characterized by the following properties

- (1) *its restriction to the subcategory of modules annihilated by \mathfrak{m} is isomorphic to the usual determinant functor (see Lemma 41.2.3), and*
- (2) *(1), (2) and (3) of Lemma 41.2.5 hold.*

Proof. Omitted. □

Lemma 41.2.7. *Let $(R, \mathfrak{m}, \kappa)$ be a local ring. Let $I \subset \mathfrak{m}$ be an ideal, and set $R' = R/I$. Let $\det_{R, \kappa}$ denote the determinant functor on the category Mod_R^f finite length R -modules and denote $\det_{R', \kappa}$ the determinant on the category $\text{Mod}_{R'}^f$ of finite length R' -modules. Then $\text{Mod}_{R'}^f \subset \text{Mod}_R^f$ is a full subcategory and there exists an isomorphism of functors*

$$\det_{R, \kappa} \big|_{\text{Mod}_{R'}^f} = \det_{R', \kappa}$$

compatible with the isomorphisms $\gamma_{K \rightarrow L \rightarrow M}$ for either of these functors.

Proof. This can be shown by using the characterization of the pair $(\det_{R', \kappa}, \gamma)$ in Lemma 41.2.6. But really the isomorphism is obtained by mapping a symbol $[x_1, \dots, x_l] \in \det_{R, \kappa}(M)$ to the corresponding symbol $[x_1, \dots, x_l] \in \det_{R', \kappa}(M)$ which “obviously” works. □

Here is a case where we can compute the determinant of a linear map. In fact there is nothing mysterious about this in any case, see Example 41.2.9 for a random example.

Lemma 41.2.8. *Let R be a local ring with residue field κ . Let $u \in R^*$ be a unit. Let M be a module of finite length over R . Denote $u_M : M \rightarrow M$ the map multiplication by u . Then*

$$\det_{\kappa}(u_M) : \det_{\kappa}(M) \longrightarrow \det_{\kappa}(M)$$

is multiplication by \bar{u}^l where $l = \text{length}_R(M)$ and $\bar{u} \in \kappa^$ is the image of u .*

Proof. Denote $f_M \in \kappa^*$ the element such that $\det_{\kappa}(u_M) = f_M \text{id}_{\det_{\kappa}(M)}$. Suppose that $0 \rightarrow K \rightarrow L \rightarrow M \rightarrow 0$ is a short exact sequence of finite R -modules. Then we see that u_K, u_L, u_M give an isomorphism of short exact sequences. Hence by Lemma 41.2.5 (1) we conclude that $f_K f_M = f_L$. This means that by induction on length it suffices to prove the lemma in the case of length 1 where it is trivial. □

Example 41.2.9. Consider the local ring $R = \mathbf{Z}_p$. Set $M = \mathbf{Z}_p/(p^2) \oplus \mathbf{Z}_p/(p^3)$. Let $u : M \rightarrow M$ be the map given by the matrix

$$u = \begin{pmatrix} a & b \\ pc & d \end{pmatrix}$$

where $a, b, c, d \in \mathbf{Z}_p$, and $a, d \in \mathbf{Z}_p^*$. In this case $\det_{\kappa}(u)$ equals multiplication by $a^2 d^3 \text{ mod } p \in \mathbf{F}_p^*$. This can easily be seen by consider the effect of u on the symbol $[p^2 e, pe, pf, e, f]$ where $e = (0, 1) \in M$ and $f = (1, 0) \in M$.

41.3. Periodic complexes

Of course there is a very general notion of periodic complexes. We can require periodicity of the maps, or periodicity of the objects. We will add these here as needed. For the moment we only need the following cases.

Definition 41.3.1. Let R be a ring.

- (1) A *2-periodic complex* over R is given by a quadruple (M, N, φ, ψ) consisting of R -modules M, N and R -module maps $\varphi : M \rightarrow N, \psi : N \rightarrow M$ such that

$$\dots \longrightarrow M \xrightarrow{\varphi} N \xrightarrow{\psi} M \xrightarrow{\varphi} N \longrightarrow \dots$$

is a complex. In this setting we define the *cohomology modules* of the complex to be the R -modules

$$H^0(M, N, \varphi, \psi) = \text{Ker}(\varphi)/\text{Im}(\psi), \quad \text{and} \quad H^1(M, N, \varphi, \psi) = \text{Ker}(\psi)/\text{Im}(\varphi).$$

We say the 2-periodic complex is *exact* if the cohomology groups are zero.

- (2) A *(2, 1)-periodic complex* over R is given by a triple (M, φ, ψ) consisting of an R -module M and R -module maps $\varphi : M \rightarrow M, \psi : M \rightarrow M$ such that

$$\dots \longrightarrow M \xrightarrow{\varphi} M \xrightarrow{\psi} M \xrightarrow{\varphi} M \longrightarrow \dots$$

is a complex. Since this is a special case of a 2-periodic complex we have its *cohomology modules* $H^0(M, \varphi, \psi), H^1(M, \varphi, \psi)$ and a notion of exactness.

In the following we will use any result proved for 2-periodic complexes without further mention for (2, 1)-periodic complexes. It is clear that the collection of 2-periodic complexes (resp. (2, 1)-periodic complexes) forms a category with morphisms $(f, g) : (M, N, \varphi, \psi) \rightarrow (M', N', \varphi', \psi')$ pairs of morphisms $f : M \rightarrow M'$ and $g : N \rightarrow N'$ such that $\varphi' \circ f = f \circ \varphi$ and $\psi' \circ g = g \circ \psi$. In fact it is an abelian category, with kernels and cokernels as in Homology, Lemma 12.12.3. Also, note that a special case are the (2, 1)-periodic complexes of the form $(M, 0, \psi)$. In this special case we have

$$H^0(M, 0, \psi) = \text{Coker}(\psi), \quad \text{and} \quad H^1(M, 0, \psi) = \text{Ker}(\psi).$$

Definition 41.3.2. Let R be a local ring. Let (M, N, φ, ψ) be a 2-periodic complex over R whose cohomology groups have finite length over R . In this case we define the *multiplicity* of (M, N, φ, ψ) to be the integer

$$e_R(M, N, \varphi, \psi) = \text{length}_R(H^0(M, N, \varphi, \psi)) - \text{length}_R(H^1(M, N, \varphi, \psi))$$

We will sometimes (especially in the case of a (2, 1)-periodic complex with $\varphi = 0$) call this the *Herbrand quotient*¹.

Lemma 41.3.3. *Let R be a local ring.*

- (1) *If (M, N, φ, ψ) is a 2-periodic complex such that M, N have finite length. Then $e_R(M, N, \varphi, \psi) = \text{length}_R(M) - \text{length}_R(N)$.*
- (2) *If (M, φ, ψ) is a (2, 1)-periodic complex such that M has finite length. Then $e_R(M, \varphi, \psi) = 0$.*

¹If the residue field of R is finite with q elements it is customary to call the Herbrand quotient $h(M, N, \varphi, \psi) = q^{e_R(M, N, \varphi, \psi)}$ which is equal to the number of elements of H^0 divided by the number of elements of H^1 .

(3) Suppose that we have a short exact sequence of $(2, 1)$ -periodic complexes

$$0 \rightarrow (M_1, N_1, \varphi_1, \psi_1) \rightarrow (M_2, N_2, \varphi_2, \psi_2) \rightarrow (M_3, N_3, \varphi_3, \psi_3) \rightarrow 0$$

If two out of three have cohomology modules of finite length so does the third and we have

$$e_R(M_2, N_2, \varphi_2, \psi_2) = e_R(M_1, N_1, \varphi_1, \psi_1) + e_R(M_3, N_3, \varphi_3, \psi_3).$$

Proof. Proof of (3). Abbreviate $A = (M_1, N_1, \varphi_1, \psi_1)$, $B = (M_2, N_2, \varphi_2, \psi_2)$ and $C = (M_3, N_3, \varphi_3, \psi_3)$. We have a long exact cohomology sequence

$$\dots \rightarrow H^1(C) \rightarrow H^0(A) \rightarrow H^0(B) \rightarrow H^0(C) \rightarrow H^1(A) \rightarrow H^1(B) \rightarrow H^1(C) \rightarrow \dots$$

This gives a finite exact sequence

$$0 \rightarrow I \rightarrow H^0(A) \rightarrow H^0(B) \rightarrow H^0(C) \rightarrow H^1(A) \rightarrow H^1(B) \rightarrow K \rightarrow 0$$

with $0 \rightarrow K \rightarrow H^1(C) \rightarrow I \rightarrow 0$ a filtration. By additivity of the length function (Algebra, Lemma 10.50.3) we see the result. The proofs of (1) and (2) are omitted. \square

Let R be a local ring with residue field κ . Let (M, φ, ψ) be a $(2, 1)$ -periodic complex over R . Assume that M has finite length and that (M, φ, ψ) is exact. We are going to use the determinant construction to define an invariant of this situation. See Section 41.2. Let us abbreviate $K_\varphi = \text{Ker}(\varphi)$, $I_\varphi = \text{Im}(\varphi)$, $K_\psi = \text{Ker}(\psi)$, and $I_\psi = \text{Im}(\psi)$. The short exact sequences

$$0 \rightarrow K_\varphi \rightarrow M \rightarrow I_\varphi \rightarrow 0, \quad 0 \rightarrow K_\psi \rightarrow M \rightarrow I_\psi \rightarrow 0$$

give isomorphisms

$$\gamma_\varphi : \det_\kappa(K_\varphi) \otimes \det_\kappa(I_\varphi) \longrightarrow \det_\kappa(M), \quad \gamma_\psi : \det_\kappa(K_\psi) \otimes \det_\kappa(I_\psi) \longrightarrow \det_\kappa(M),$$

see Lemma 41.2.5. On the other hand the exactness of the complex gives equalities $K_\varphi = I_\psi$, and $K_\psi = I_\varphi$ and hence an isomorphism

$$\sigma : \det_\kappa(K_\varphi) \otimes \det_\kappa(I_\varphi) \longrightarrow \det_\kappa(K_\psi) \otimes \det_\kappa(I_\psi)$$

by switching the factors. Using this notation we can define our invariant.

Definition 41.3.4. Let R be a local ring with residue field κ . Let (M, φ, ψ) be a $(2, 1)$ -periodic complex over R . Assume that M has finite length and that (M, φ, ψ) is exact. The *determinant* of (M, φ, ψ) is the element

$$\det_\kappa(M, \varphi, \psi) \in \kappa^*$$

such that the composition

$$\det_\kappa(M) \xrightarrow{\gamma_\psi \circ \sigma \circ \gamma_\varphi^{-1}} \det_\kappa(M)$$

is multiplication by $(-1)^{\text{length}_R(I_\varphi)\text{length}_R(I_\psi)} \det_\kappa(M, \varphi, \psi)$.

Remark 41.3.5. Here is a more down to earth description of the determinant introduced above. Let R be a local ring with residue field κ . Let (M, φ, ψ) be a $(2, 1)$ -periodic complex over R . Assume that M has finite length and that (M, φ, ψ) is exact. Let us abbreviate $I_\varphi = \text{Im}(\varphi)$, $I_\psi = \text{Im}(\psi)$ as above. Assume that $\text{length}_R(I_\varphi) = a$ and $\text{length}_R(I_\psi) = b$, so that $a + b = \text{length}_R(M)$ by exactness. Choose admissible sequences $x_1, \dots, x_a \in I_\varphi$ and $y_1, \dots, y_b \in I_\psi$ such that the symbol $[x_1, \dots, x_a]$ generates $\det_\kappa(I_\varphi)$ and the symbol $[x_1, \dots, x_b]$ generates $\det_\kappa(I_\psi)$.

Choose $\tilde{x}_i \in M$ such that $\varphi(\tilde{x}_i) = x_i$. Choose $\tilde{y}_j \in M$ such that $\psi(\tilde{y}_j) = y_j$. Then $\det_\kappa(M, \varphi, \psi)$ is characterized by the equality

$$[x_1, \dots, x_a, \tilde{y}_1, \dots, \tilde{y}_b] = (-1)^{ab} \det_\kappa(M, \varphi, \psi)[y_1, \dots, y_b, \tilde{x}_1, \dots, \tilde{x}_a]$$

in $\det_\kappa(M)$. This also explains the sign.

Lemma 41.3.6. *Let R be a local ring with residue field κ . Let (M, φ, ψ) be a $(2, 1)$ -periodic complex over R . Assume that M has finite length and that (M, φ, ψ) is exact. Then*

$$\det_\kappa(M, \varphi, \psi) \det_\kappa(M, \psi, \varphi) = 1.$$

Proof. Omitted. □

Lemma 41.3.7. *Let R be a local ring with residue field κ . Let (M, φ, φ) be a $(2, 1)$ -periodic complex over R . Assume that M has finite length and that (M, φ, φ) is exact. Then $\text{length}_R(M) = 2\text{length}_R(\text{Im}(\varphi))$ and*

$$\det_\kappa(M, \varphi, \psi) = (-1)^{\text{length}_R(\text{Im}(\varphi))} = (-1)^{\frac{1}{2}\text{length}_R(M)}$$

Proof. Follows directly from the sign rule in the definitions. □

Lemma 41.3.8. *Let R be a local ring with residue field κ . Let M be a finite length R -module.*

- (1) *if $\varphi : M \rightarrow M$ is an isomorphism then $\det_\kappa(M, \varphi, 0) = \det_\kappa(\varphi)$.*
- (2) *if $\psi : M \rightarrow M$ is an isomorphism then $\det_\kappa(M, 0, \psi) = \det_\kappa(\psi)^{-1}$.*

Proof. Let us prove (1). Set $\psi = 0$. Then we may, with notation as above Definition 41.3.4, identify $K_\varphi = I_\psi = 0$, $I_\varphi = K_\psi = M$. With these identifications, the map

$$\gamma_\varphi : \kappa \otimes \det_\kappa(M) = \det_\kappa(K_\varphi) \otimes \det_\kappa(I_\varphi) \longrightarrow \det_\kappa(M)$$

is identified with $\det_\kappa(\varphi^{-1})$. On the other hand the map γ_ψ is identified with the identity map. Hence $\gamma_\psi \circ \sigma \circ \gamma_\varphi^{-1}$ is equal to $\det_\kappa(\varphi)$ in this case. Whence the result. We omit the proof of (2). □

Lemma 41.3.9. *Let R be a local ring with residue field κ . Suppose that we have a short exact sequence of $(2, 1)$ -periodic complexes*

$$0 \rightarrow (M_1, \varphi_1, \psi_1) \rightarrow (M_2, \varphi_2, \psi_2) \rightarrow (M_3, \varphi_3, \psi_3) \rightarrow 0$$

with all M_i of finite length, and each (M_1, φ_1, ψ_1) exact. Then

$$\det_\kappa(M_2, \varphi_2, \psi_2) = \det_\kappa(M_1, \varphi_1, \psi_1) \det_\kappa(M_3, \varphi_3, \psi_3).$$

in κ^ .*

Proof. Let us abbreviate $I_{\varphi,i} = \text{Im}(\varphi_i)$, $K_{\varphi,i} = \text{Ker}(\varphi_i)$, $I_{\psi,i} = \text{Im}(\psi_i)$, and $K_{\psi,i} = \text{Ker}(\psi_i)$. Observe that we have a commutative square

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & K_{\varphi,1} & \longrightarrow & K_{\varphi,2} & \longrightarrow & K_{\varphi,3} \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & M_1 & \longrightarrow & M_2 & \longrightarrow & M_3 \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & I_{\varphi,1} & \longrightarrow & I_{\varphi,2} & \longrightarrow & I_{\varphi,3} \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0
 \end{array}$$

of finite length R -modules with exact rows and columns. The top row is exact since it can be identified with the sequence $I_{\psi,1} \rightarrow I_{\psi,2} \rightarrow I_{\psi,3} \rightarrow 0$ of images, and similarly for the bottom row. There is a similar diagram involving the modules $I_{\psi,i}$ and $K_{\psi,i}$. By definition $\det_{\kappa}(M_2, \varphi_2, \psi_2)$ corresponds, up to a sign, to the composition of the left vertical maps in the following diagram

$$\begin{array}{ccc}
 \det_{\kappa}(M_1) \otimes \det_{\kappa}(M_3) & \xrightarrow{\gamma} & \det_{\kappa}(M_2) \\
 \downarrow \gamma^{-1} \otimes \gamma^{-1} & & \downarrow \gamma^{-1} \\
 \det_{\kappa}(K_{\varphi,1}) \otimes \det_{\kappa}(I_{\varphi,1}) \otimes \det_{\kappa}(K_{\varphi,3}) \otimes \det_{\kappa}(I_{\varphi,3}) & \xrightarrow{\gamma \otimes \gamma} & \det_{\kappa}(K_{\varphi,2}) \otimes \det_{\kappa}(I_{\varphi,2}) \\
 \downarrow \sigma \otimes \sigma & & \downarrow \sigma \\
 \det_{\kappa}(K_{\psi,1}) \otimes \det_{\kappa}(I_{\psi,1}) \otimes \det_{\kappa}(K_{\psi,3}) \otimes \det_{\kappa}(I_{\psi,3}) & \xrightarrow{\gamma \otimes \gamma} & \det_{\kappa}(K_{\psi,2}) \otimes \det_{\kappa}(I_{\psi,2}) \\
 \downarrow \gamma \otimes \gamma & & \downarrow \gamma \\
 \det_{\kappa}(M_1) \otimes \det_{\kappa}(M_3) & \xrightarrow{\gamma} & \det_{\kappa}(M_2)
 \end{array}$$

The top and bottom squares are commutative up to sign by applying Lemma 41.2.5 (2). The middle square is trivially commutative (we are just switching factors). Hence we see that $\det_{\kappa}(M_2, \varphi_2, \psi_2) = \epsilon \det_{\kappa}(M_1, \varphi_1, \psi_1) \det_{\kappa}(M_3, \varphi_3, \psi_3)$ for some sign ϵ . And the sign can be worked out, namely the outer rectangle in the diagram above commutes up to

$$\begin{aligned}
 \epsilon &= (-1)^{\text{length}(I_{\varphi,1})\text{length}(K_{\varphi,3}) + \text{length}(I_{\psi,1})\text{length}(K_{\psi,3})} \\
 &= (-1)^{\text{length}(I_{\varphi,1})\text{length}(I_{\psi,3}) + \text{length}(I_{\psi,1})\text{length}(I_{\varphi,3})}
 \end{aligned}$$

(proof omitted). It follows easily from this that the signs work out as well. \square

Example 41.3.10. Let k be a field. Consider the ring $R = k[T]/(T^2)$ of dual numbers over k . Denote t the class of T in R . Let $M = R$ and $\varphi = ut$, $\psi = vt$ with $u, v \in k^*$. In this case $\det_k(M)$ has generator $e = [t, 1]$. We identify $I_{\varphi} = K_{\varphi} = I_{\psi} = K_{\psi} = (t)$. Then $\gamma_{\varphi}(t \otimes t) = u^{-1}[t, 1]$ (since $u^{-1} \in M$ is a lift of $t \in I_{\varphi}$) and $\gamma_{\psi}(t \otimes t) = v^{-1}[t, 1]$ (same reason). Hence we see that $\det_k(M, \varphi, \psi) = -u/v \in k^*$.

Example 41.3.11. Let $R = \mathbf{Z}_p$ and let $M = \mathbf{Z}_p/(p^l)$. Let $\varphi = p^b u$ and $\psi = p^a v$ with $a, b \geq 0, a + b = l$ and $u, v \in \mathbf{Z}_p^*$. Then a computation as in Example 41.3.10 shows that

$$\begin{aligned} \det_{\mathbf{F}_p}(\mathbf{Z}_p/(p^l), p^b u, p^a v) &= (-1)^{ab} u^a / v^b \pmod p \\ &= (-1)^{\text{ord}_p(\alpha)\text{ord}_p(\beta)} \frac{\alpha^{\text{ord}_p(\beta)}}{\beta^{\text{ord}_p(\alpha)}} \pmod p \end{aligned}$$

with $\alpha = p^b u, \beta = p^a v \in \mathbf{Z}_p$. See Lemma 41.4.10 for a more general case (and a proof).

Example 41.3.12. Let $R = k$ be a field. Let $M = k^{\oplus a} \oplus k^{\oplus b}$ be $l = a + b$ dimensional. Let φ and ψ be the following diagonal matrices

$$\varphi = \text{diag}(u_1, \dots, u_a, 0, \dots, 0), \quad \psi = \text{diag}(0, \dots, 0, v_1, \dots, v_b)$$

with $u_i, v_j \in k^*$. In this case we have

$$\det_k(M, \varphi, \psi) = \frac{u_1 \dots u_a}{v_1 \dots v_b}.$$

This can be seen by a direct computation or by computing in case $l = 1$ and using the additivity of Lemma 41.3.9.

Example 41.3.13. Let $R = k$ be a field. Let $M = k^{\oplus a} \oplus k^{\oplus a}$ be $l = 2a$ dimensional. Let φ and ψ be the following block matrices

$$\varphi = \begin{pmatrix} 0 & U \\ 0 & 0 \end{pmatrix}, \quad \psi = \begin{pmatrix} 0 & V \\ 0 & 0 \end{pmatrix},$$

with $U, V \in \text{Mat}(a \times a, k)$ invertible. In this case we have

$$\det_k(M, \varphi, \psi) = (-1)^a \frac{\det(U)}{\det(V)}.$$

This can be seen by a direct computation. The case $a = 1$ is similar to the computation in Example 41.3.10.

Example 41.3.14. Let $R = k$ be a field. Let $M = k^{\oplus 4}$. Let

$$\varphi = \begin{pmatrix} 0 & 0 & 0 & 0 \\ u_1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & u_2 & 0 \end{pmatrix} \quad \psi = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & v_2 & 0 \\ 0 & 0 & 0 & 0 \\ v_1 & 0 & 0 & 0 \end{pmatrix}$$

with $u_1, u_2, v_1, v_2 \in k^*$. Then we have

$$\det_k(M, \varphi, \psi) = -\frac{u_1 u_2}{v_1 v_2}.$$

Next we come to the analogue of the fact that the determinant of a composition of linear endomorphisms is the product of the determinants. To avoid very long formulae we write $I_\varphi = \text{Im}(\varphi)$, and $K_\varphi = \text{Ker}(\varphi)$ for any R -module map $\varphi : M \rightarrow M$. We also denote $\varphi\psi = \varphi \circ \psi$ for a pair of morphisms $\varphi, \psi : M \rightarrow M$.

Lemma 41.3.15. *Let R be a local ring with residue field κ . Let M be a finite length R -module. Let α, β, γ be endomorphisms of M . Assume that*

- (1) $I_\alpha = K_{\beta\gamma}$, and similarly for any permutation of α, β, γ ,
- (2) $K_\alpha = I_{\beta\gamma}$, and similarly for any permutation of α, β, γ .

Then

- (1) *The triple $(M, \alpha, \beta\gamma)$ is an exact $(2, 1)$ -periodic complex.*
- (2) *The triple $(I_\gamma, \alpha, \beta)$ is an exact $(2, 1)$ -periodic complex.*
- (3) *The triple $(M/K_\beta, \alpha, \gamma)$ is an exact $(2, 1)$ -periodic complex.*
- (4) *We have*

$$\det_\kappa(M, \alpha, \beta\gamma) = \det_\kappa(I_\gamma, \alpha, \beta) \det_\kappa(M/K_\beta, \alpha, \gamma).$$

Proof. It is clear that the assumptions imply part (1) of the lemma.

To see part (1) note that the assumptions imply that $I_{\gamma\alpha} = I_{\alpha\gamma}$, and similarly for kernels and any other pair of morphisms. Moreover, we see that $I_{\gamma\beta} = I_{\beta\gamma} = K_\alpha \subset I_\gamma$ and similarly for any other pair. In particular we get a short exact sequence

$$0 \rightarrow I_{\beta\gamma} \rightarrow I_\gamma \xrightarrow{\alpha} I_{\alpha\gamma} \rightarrow 0$$

and similarly we get a short exact sequence

$$0 \rightarrow I_{\alpha\gamma} \rightarrow I_\gamma \xrightarrow{\beta} I_{\beta\gamma} \rightarrow 0.$$

This proves $(I_\gamma, \alpha, \beta)$ is an exact $(2, 1)$ -periodic complex. Hence part (2) of the lemma holds.

To see that α, γ give well defined endomorphisms of M/K_β we have to check that $\alpha(K_\beta) \subset K_\beta$ and $\gamma(K_\beta) \subset K_\beta$. This is true because $\alpha(K_\beta) = \alpha(I_\gamma\alpha) = I_{\alpha\gamma\alpha} \subset I_{\alpha\gamma} = K_\beta$, and similarly in the other case. The kernel of the map $\alpha : M/K_\beta \rightarrow M/K_\beta$ is $K_{\beta\alpha}/K_\beta = I_\gamma/K_\beta$. Similarly, the kernel of $\gamma : M/K_\beta \rightarrow M/K_\beta$ is equal to I_α/K_β . Hence we conclude that (3) holds.

We introduce $r = \text{length}_R(K_\alpha)$, $s = \text{length}_R(K_\beta)$ and $t = \text{length}_R(K_\gamma)$. By the exact sequences above and our hypotheses we have $\text{length}_R(I_\alpha) = s + t$, $\text{length}_R(I_\beta) = r + t$, $\text{length}_R(I_\gamma) = r + s$, and $\text{length}(M) = r + s + t$. Choose

- (1) an admissible sequence $x_1, \dots, x_r \in K_\alpha$ generating K_α
- (2) an admissible sequence $y_1, \dots, y_s \in K_\beta$ generating K_β ,
- (3) an admissible sequence $z_1, \dots, z_t \in K_\gamma$ generating K_γ ,
- (4) elements $\tilde{x}_i \in M$ such that $\beta\gamma\tilde{x}_i = x_i$,
- (5) elements $\tilde{y}_i \in M$ such that $\alpha\gamma\tilde{y}_i = y_i$,
- (6) elements $\tilde{z}_i \in M$ such that $\beta\alpha\tilde{z}_i = z_i$.

With these choices the sequence $y_1, \dots, y_s, \alpha\tilde{z}_1, \dots, \alpha\tilde{z}_t$ is an admissible sequence in I_α generating it. Hence, by Remark 41.3.5 the determinant $D = \det_\kappa(M, \alpha, \beta\gamma)$ is the unique element of κ^* such that

$$\begin{aligned} & [y_1, \dots, y_s, \alpha\tilde{z}_1, \dots, \alpha\tilde{z}_t, \tilde{x}_1, \dots, \tilde{x}_r] \\ &= (-1)^{r(s+t)} D[x_1, \dots, x_r, \gamma\tilde{y}_1, \dots, \gamma\tilde{y}_s, \tilde{z}_1, \dots, \tilde{z}_t] \end{aligned}$$

By the same remark, we see that $D_1 = \det_\kappa(M/K_\beta, \alpha, \gamma)$ is characterized by

$$[y_1, \dots, y_s, \alpha\tilde{z}_1, \dots, \alpha\tilde{z}_t, \tilde{x}_1, \dots, \tilde{x}_r] = (-1)^{rt} D_1[y_1, \dots, y_s, \gamma\tilde{x}_1, \dots, \gamma\tilde{x}_r, \tilde{z}_1, \dots, \tilde{z}_t]$$

By the same remark, we see that $D_2 = \det_\kappa(I_\gamma, \alpha, \beta)$ is characterized by

$$[y_1, \dots, y_s, \gamma\tilde{x}_1, \dots, \gamma\tilde{x}_r, \tilde{z}_1, \dots, \tilde{z}_t] = (-1)^{rs} D_2[x_1, \dots, x_r, \gamma\tilde{y}_1, \dots, \gamma\tilde{y}_s, \tilde{z}_1, \dots, \tilde{z}_t]$$

Combining the formulas above we see that $D = D_1 D_2$ as desired. □

Lemma 41.3.16. *Let R be a local ring with residue field κ . Let $\alpha : (M, \varphi, \psi) \rightarrow (M', \varphi', \psi')$ be a morphism of $(2, 1)$ -periodic complexes over R . Assume*

- (1) *M, M' have finite length,*

- (2) $(M, \varphi, \psi), (M', \varphi', \psi')$ are exact,
- (3) the maps φ, ψ induce the zero map on $K = \text{Ker}(\alpha)$, and
- (4) the maps φ, ψ induce the zero map on $Q = \text{Coker}(\alpha)$.

Denote $N = \alpha(M) \subset M'$. We obtain two short exact sequences of $(2, 1)$ -periodic complexes

$$\begin{aligned} 0 \rightarrow (N, \varphi', \psi') \rightarrow (M', \varphi', \psi') \rightarrow (Q, 0, 0) \rightarrow 0 \\ 0 \rightarrow (K, 0, 0) \rightarrow (M, \varphi, \psi) \rightarrow (N, \varphi', \psi') \rightarrow 0 \end{aligned}$$

which induce two isomorphisms $\alpha_i : Q \rightarrow K, i = 0, 1$. Then

$$\det_{\kappa}(M, \varphi, \psi) = \det_{\kappa}(\alpha_0^{-1} \circ \alpha_1) \det_{\kappa}(M', \varphi', \psi')$$

In particular, if $\alpha_0 = \alpha_1$, then $\det_{\kappa}(M, \varphi, \psi) = \det_{\kappa}(M', \varphi', \psi')$.

Proof. There are (at least) two ways to prove this lemma. One is to produce an enormous commutative diagram using the properties of the determinants. The other is to use the characterization of the determinants in terms of admissible sequences of elements. It is the second approach that we will use.

First let us explain precisely what the maps α_i are. Namely, α_0 is the composition

$$\alpha_0 : Q = H^0(Q, 0, 0) \rightarrow H^1(N, \varphi', \psi') \rightarrow H^2(K, 0, 0) = K$$

and α_1 is the composition

$$\alpha_1 : Q = H^1(Q, 0, 0) \rightarrow H^2(N, \varphi', \psi') \rightarrow H^3(K, 0, 0) = K$$

coming from the boundary maps of the short exact sequences of complexes displayed in the lemma. The fact that the complexes $(M, \varphi, \psi), (M', \varphi', \psi')$ are exact implies these maps are isomorphisms.

We will use the notation $I_{\varphi} = \text{Im}(\varphi), K_{\varphi} = \text{Ker}(\varphi)$ and similarly for the other maps. Exactness for M and M' means that $K_{\varphi} = I_{\psi}$ and three similar equalities. We introduce $k = \text{length}_R(K), a = \text{length}_R(I_{\varphi}), b = \text{length}_R(I_{\psi})$. Then we see that $\text{length}_R(M) = a + b$, and $\text{length}_R(N) = a + b - k, \text{length}_R(Q) = k$ and $\text{length}_R(M') = a + b$. The exact sequences below will show that also $\text{length}_R(I_{\varphi'}) = a$ and $\text{length}_R(I_{\psi'}) = b$.

The assumption that $K \subset K_{\varphi} = I_{\psi}$ means that φ factors through N to give an exact sequence

$$0 \rightarrow \alpha(I_{\psi}) \rightarrow N \xrightarrow{\varphi\alpha^{-1}} I_{\psi} \rightarrow 0.$$

Here $\varphi\alpha^{-1}(x') = y$ means $x' = \alpha(x)$ and $y = \varphi(x)$. Similarly, we have

$$0 \rightarrow \alpha(I_{\varphi}) \rightarrow N \xrightarrow{\psi\alpha^{-1}} I_{\varphi} \rightarrow 0.$$

The assumption that ψ' induces the zero map on Q means that $I_{\psi'} = K_{\varphi'} \subset N$. This means the quotient $\varphi'(N) \subset I_{\varphi'}$ is identified with Q . Note that $\varphi'(N) = \alpha(I_{\varphi})$. Hence we conclude there is an isomorphism

$$\varphi' : Q \rightarrow I_{\varphi'} / \alpha(I_{\varphi})$$

simply described by $\varphi'(x' \text{ mod } N) = \varphi'(x') \text{ mod } \alpha(I_{\varphi})$. In exactly the same way we get

$$\psi' : Q \rightarrow I_{\psi'} / \alpha(I_{\psi})$$

Finally, note that α_0 is the composition

$$Q \xrightarrow{\varphi'} I_{\varphi'} / \alpha(I_{\varphi}) \xrightarrow{\psi\alpha^{-1}|_{I_{\varphi'} / \alpha(I_{\varphi})}} K$$

and similarly $\alpha_1 = \varphi\alpha^{-1}|_{I_{\psi'}/\alpha(I_\psi)} \circ \psi'$.

To shorten the formulas below we are going to write αx instead of $\alpha(x)$ in the following. No confusion should result since all maps are indicated by greek letters and elements by roman letters. We are going to choose

- (1) an admissible sequence $z_1, \dots, z_k \in K$ generating K ,
- (2) elements $z'_i \in M$ such that $\varphi z'_i = z_i$,
- (3) elements $z''_i \in M$ such that $\psi z''_i = z_i$,
- (4) elements $x_{k+1}, \dots, x_a \in I_\varphi$ such that $z_1, \dots, z_k, x_{k+1}, \dots, x_a$ is an admissible sequence generating I_φ ,
- (5) elements $\tilde{x}_i \in M$ such that $\varphi \tilde{x}_i = x_i$,
- (6) elements $y_{k+1}, \dots, y_b \in I_\psi$ such that $z_1, \dots, z_k, y_{k+1}, \dots, y_b$ is an admissible sequence generating I_ψ ,
- (7) elements $\tilde{y}_i \in M$ such that $\psi \tilde{y}_i = y_i$, and
- (8) elements $w_1, \dots, w_k \in M'$ such that $w_1 \bmod N, \dots, w_k \bmod N$ are an admissible sequence in Q generating Q .

By Remark 41.3.5 the element $D = \det_\kappa(M, \varphi, \psi) \in \kappa^*$ is characterized by

$$\begin{aligned} & [z_1, \dots, z_k, x_{k+1}, \dots, x_a, z'_1, \dots, z'_k, \tilde{y}_{k+1}, \dots, \tilde{y}_b] \\ &= (-1)^{ab} D [z_1, \dots, z_k, y_{k+1}, \dots, y_b, z'_1, \dots, z'_k, \tilde{x}_{k+1}, \dots, \tilde{x}_a] \end{aligned}$$

Note that by the discussion above $\alpha x_{k+1}, \dots, \alpha x_a, \varphi w_1, \dots, \varphi w_k$ is an admissible sequence generating $I_{\varphi'}$ and $\alpha y_{k+1}, \dots, \alpha y_b, \psi w_1, \dots, \psi w_k$ is an admissible sequence generating $I_{\psi'}$. Hence by Remark 41.3.5 the element $D' = \det_\kappa(M', \varphi', \psi') \in \kappa^*$ is characterized by

$$\begin{aligned} & [\alpha x_{k+1}, \dots, \alpha x_a, \varphi' w_1, \dots, \varphi' w_k, \alpha \tilde{y}_{k+1}, \dots, \alpha \tilde{y}_b, w_1, \dots, w_k] \\ &= (-1)^{ab} D' [\alpha y_{k+1}, \dots, \alpha y_b, \psi' w_1, \dots, \psi' w_k, \alpha \tilde{x}_{k+1}, \dots, \alpha \tilde{x}_a, w_1, \dots, w_k] \end{aligned}$$

Note how in the first, resp. second displayed formula the the first, resp. last k entries of the symbols on both sides are the same. Hence these formulas are really equivalent to the equalities

$$\begin{aligned} & [\alpha x_{k+1}, \dots, \alpha x_a, \alpha z'_1, \dots, \alpha z'_k, \alpha \tilde{y}_{k+1}, \dots, \alpha \tilde{y}_b] \\ &= (-1)^{ab} D [\alpha y_{k+1}, \dots, \alpha y_b, \alpha z'_1, \dots, \alpha z'_k, \alpha \tilde{x}_{k+1}, \dots, \alpha \tilde{x}_a] \end{aligned}$$

and

$$\begin{aligned} & [\alpha x_{k+1}, \dots, \alpha x_a, \varphi' w_1, \dots, \varphi' w_k, \alpha \tilde{y}_{k+1}, \dots, \alpha \tilde{y}_b] \\ &= (-1)^{ab} D' [\alpha y_{k+1}, \dots, \alpha y_b, \psi' w_1, \dots, \psi' w_k, \alpha \tilde{x}_{k+1}, \dots, \alpha \tilde{x}_a] \end{aligned}$$

in $\det_\kappa(N)$. Note that $\varphi' w_1, \dots, \varphi' w_k$ and $\alpha z'_1, \dots, \alpha z'_k$ are admissible sequences generating the module $I_{\varphi'}/\alpha(I_\varphi)$. Write

$$[\varphi' w_1, \dots, \varphi' w_k] = \lambda_0 [\alpha z'_1, \dots, \alpha z'_k]$$

in $\det_\kappa(I_{\varphi'}/\alpha(I_\varphi))$ for some $\lambda_0 \in \kappa^*$. Similarly, write

$$[\psi' w_1, \dots, \psi' w_k] = \lambda_1 [\alpha z'_1, \dots, \alpha z'_k]$$

in $\det_\kappa(I_{\psi'}/\alpha(I_\psi))$ for some $\lambda_1 \in \kappa^*$. On the one hand it is clear that

$$\alpha_i([w_1, \dots, w_k]) = \lambda_i [z_1, \dots, z_k]$$

for $i = 0, 1$ by our description of α_i above, which means that

$$\det_\kappa(\alpha_0^{-1} \circ \alpha_1) = \lambda_1 / \lambda_0$$

and on the other hand it is clear that

$$\begin{aligned} & \lambda_0[\alpha x_{k+1}, \dots, \alpha x_a, \alpha z''_1, \dots, \alpha z''_k, \alpha \tilde{y}_{k+1}, \dots, \alpha \tilde{y}_b] \\ &= [\alpha x_{k+1}, \dots, \alpha x_a, \varphi' w_1, \dots, \varphi' w_k, \alpha \tilde{y}_{k+1}, \dots, \alpha \tilde{y}_b] \end{aligned}$$

and

$$\begin{aligned} & \lambda_1[\alpha y_{k+1}, \dots, \alpha y_b, \alpha z'_1, \dots, \alpha z'_k, \alpha \tilde{x}_{k+1}, \dots, \alpha \tilde{x}_a] \\ &= [\alpha y_{k+1}, \dots, \alpha y_b, \psi' w_1, \dots, \psi' w_k, \alpha \tilde{x}_{k+1}, \dots, \alpha \tilde{x}_a] \end{aligned}$$

which imply $\lambda_0 D = \lambda_1 D'$. The lemma follows. □

41.4. Symbols

The correct generality for this construction is perhaps the situation of the following lemma.

Lemma 41.4.1. *Let A be a Noetherian local ring. Let M be a finite A -module of dimension 1. Assume $\varphi, \psi : M \rightarrow M$ are two injective A -module maps, and assume $\varphi(\psi(M)) = \psi(\varphi(M))$, for example if φ and ψ commute. Then $\text{length}_R(M/\varphi\psi M) < \infty$ and $(M/\varphi\psi M, \varphi, \psi)$ is an exact $(2, 1)$ -periodic complex.*

Proof. Let \mathfrak{q} be a minimal prime of the support of M . Then $M_{\mathfrak{q}}$ is a finite length $A_{\mathfrak{q}}$ -module, see Algebra, Lemma 10.61.3. Hence both φ and ψ induce isomorphisms $M_{\mathfrak{q}} \rightarrow M_{\mathfrak{q}}$. Thus the support of $M/\varphi\psi M$ is $\{\mathfrak{m}_A\}$ and hence it has finite length (see lemma cited above). Finally, the kernel of φ on $M/\varphi\psi M$ is clearly $\psi M/\varphi\psi M$, and hence the kernel of φ is the image of ψ on $M/\varphi\psi M$. Similarly the other way since $M/\varphi\psi M = M/\psi\varphi M$ by assumption. □

Lemma 41.4.2. *Let A be a Noetherian local ring. Let $a, b \in A$.*

- (1) *If M is a finite A -module of dimension 1 such that a, b are nonzerodivisors on M , then $\text{length}_A(M/abM) < \infty$ and $(M/abM, a, b)$ is a $(2, 1)$ -periodic exact complex.*
- (2) *If a, b are nonzerodivisors and $\dim(A) = 1$ then $\text{length}_A(A/(ab)) < \infty$ and $(A/(ab), a, b)$ is a $(2, 1)$ -periodic exact complex.*

In particular, in these cases $\det_{\kappa}(M/abM, a, b) \in \kappa^$, resp. $\det_{\kappa}(A/(ab), a, b) \in \kappa^*$ are defined.*

Proof. Follows from Lemma 41.4.1. □

Definition 41.4.3. Let A be a Noetherian local ring with residue field κ . Let $a, b \in A$. Let M be a finite A -module of dimension 1 such that a, b are nonzerodivisors on M . We define the *symbol associated to M, a, b* to be the element

$$d_M(a, b) = \det_{\kappa}(M/abM, a, b) \in \kappa^*$$

Lemma 41.4.4. *Let A be a Noetherian local ring. Let $a, b, c \in A$. Let M be a finite A -module with $\dim(M) = 1$. Assume a, b, c are nonzerodivisors on M . Then*

$$d_M(a, bc) = d_M(a, b)d_M(a, c)$$

and $d_M(a, b)d_M(b, a) = 1$.

Proof. The first statement is immediate from Lemma 41.3.15 above. The second comes from Lemma 41.3.6. □

Definition 41.4.5. Let A be a Noetherian local domain of dimension 1 with residue field κ . Let K be the fraction field of A . We define the *tame symbol* of A to be the map

$$K^* \times K^* \longrightarrow \kappa^*, \quad (x, y) \longmapsto d_A(x, y)$$

where $d_A(x, y)$ is extended to $K^* \times K^*$ by the multiplicativity of Lemma 41.4.4.

It is clear that we may extend more generally $d_M(-, -)$ to certain rings of fractions of A (even if A is not a domain).

Lemma 41.4.6. *Let A be a Noetherian local ring. Let M be a finite A -module of dimension 1. Let $b \in A$ be a nonzerodivisor on M , and let $u \in A^*$. Then*

$$d_M(u, b) = u^{\text{length}_M(M/bM)} \pmod{\mathfrak{m}_A}.$$

In particular, if $M = A$, then $d_A(u, b) = u^{\text{ord}_A(b)} \pmod{\mathfrak{m}_A}$.

Proof. Note that in this case $M/ubM = M/bM$ on which multiplication by b is zero. Hence $d_M(u, b) = \det_{\kappa}(u|_{M/bM})$ by Lemma 41.3.8. The lemma then follows from Lemma 41.2.8. \square

Lemma 41.4.7. *Let A be a Noetherian local ring. Let $a, b \in A$. Let*

$$0 \rightarrow M \rightarrow M' \rightarrow M'' \rightarrow 0$$

be a short exact sequence of A -modules of dimension 1 such that a, b are nonzerodivisors on all three A -modules. Then

$$d_{M'}(a, b) = d_M(a, b)d_{M''}(a, b)$$

in κ^ .*

Proof. It is easy to see that this leads to a short exact sequence of exact $(2, 1)$ -periodic complexes

$$0 \rightarrow (M/abM, a, b) \rightarrow (M'/abM', a, b) \rightarrow (M''/abM'', a, b) \rightarrow 0$$

Hence the lemma follows from Lemma 41.3.9. \square

Lemma 41.4.8. *Let A be a Noetherian local ring. Let $\alpha : M \rightarrow M'$ be a homomorphism of finite A -modules of dimension 1. Let $a, b \in A$. Assume*

- (1) a, b are nonzerodivisors on both M and M' , and
- (2) $\dim(\text{Ker}(\alpha)), \dim(\text{Coker}(\alpha)) \leq 0$.

Then $d_M(a, b) = d_{M'}(a, b)$.

Proof. If $a \in A^*$, then the equality follows from the equality $\text{length}(M/bM) = \text{length}(M'/bM')$ and Lemma 41.4.6. Similarly if b is a unit the lemma holds as well (by the symmetry of Lemma 41.4.4). Hence we may assume that $a, b \in \mathfrak{m}_A$. This in particular implies that \mathfrak{m} is not an associated prime of M , and hence $\alpha : M \rightarrow M'$ is injective. This permits us to think of M as a submodule of M' . By assumption M'/M is a finite A -module with support $\{\mathfrak{m}_A\}$ and hence has finite length. Note that for any third module M'' with $M \subset M'' \subset M'$ the maps $M \rightarrow M''$ and $M'' \rightarrow M'$ satisfy the assumptions of the lemma as well. This reduces us, by induction on the length of M'/M , to the case where $\text{length}_A(M'/M) = 1$. Finally, in this case consider the map

$$\bar{\alpha} : M/abM \longrightarrow M'/abM'.$$

By construction the cokernel Q of $\bar{\alpha}$ has length 1. Since $a, b \in \mathfrak{m}_A$, they act trivially on Q . It also follows that the kernel K of $\bar{\alpha}$ has length 1 and hence also a, b act trivially on K . Hence we may apply Lemma 41.3.16. Thus it suffices to see that the two maps $\alpha_i : Q \rightarrow K$ are the same. In fact, both maps are equal to the map $q = x' \bmod \text{Im}(\bar{\alpha}) \mapsto abx' \in K$. We omit the verification. \square

Lemma 41.4.9. *Let A be a Noetherian local ring. Let M be a finite A -module with $\dim(M) = 1$. Let $a, b \in A$ nonzerodivisors on M . Let $\mathfrak{q}_1, \dots, \mathfrak{q}_t$ be the minimal primes in the support of M . Then*

$$d_M(a, b) = \prod_{i=1, \dots, t} d_{A/\mathfrak{q}_i}(a, b)^{\text{length}_{A/\mathfrak{q}_i}(M_{\mathfrak{q}_i})}$$

as elements of κ^* .

Proof. Choose a filtration by A -submodules

$$0 = M_0 \subset M_1 \subset \dots \subset M_n = M$$

such that each quotient M_j/M_{j-1} is isomorphic to A/\mathfrak{p}_j for some prime ideal \mathfrak{p}_j of A . See Algebra, Lemma 10.61.1. For each j we have either $\mathfrak{p}_j = \mathfrak{q}_i$ for some i , or $\mathfrak{p}_j = \mathfrak{m}_A$. Moreover, for a fixed i , the number of j such that $\mathfrak{p}_j = \mathfrak{q}_i$ is equal to $\text{length}_{A/\mathfrak{q}_i}(M_{\mathfrak{q}_i})$ by Algebra, Lemma 10.61.5. Hence $d_{M_j}(a, b)$ is defined for each j and

$$d_{M_j}(a, b) = \begin{cases} d_{M_{j-1}}(a, b)d_{A/\mathfrak{q}_i}(a, b) & \text{if } \mathfrak{p}_j = \mathfrak{q}_i \\ d_{M_{j-1}}(a, b) & \text{if } \mathfrak{p}_j = \mathfrak{m}_A \end{cases}$$

by Lemma 41.4.7 in the first instance and Lemma 41.4.8 in the second. Hence the lemma. \square

Lemma 41.4.10. *Let A be a discrete valuation ring with fraction field K . For nonzero $x, y \in K$ we have*

$$d_A(x, y) = (-1)^{\text{ord}_A(x)\text{ord}_A(y)} \frac{x^{\text{ord}_A(y)}}{y^{\text{ord}_A(x)}} \bmod \mathfrak{m}_A,$$

in other words the symbol is equal to the usual tame symbol.

Proof. By multiplicativity it suffices to prove this when $x, y \in A$. Let $t \in A$ be a uniformizer. Write $x = t^b u$ and $y = t^a v$ for some $a, b \geq 0$ and $u, v \in A^*$. Set $l = a + b$. Then t^{l-1}, \dots, t^b is an admissible sequence in $(x)/(xy)$ and t^{l-1}, \dots, t^a is an admissible sequence in $(y)/(xy)$. Hence by Remark 41.3.5 we see that $d_A(x, y)$ is characterized by the equation

$$[t^{l-1}, \dots, t^b, v^{-1}t^{b-1}, \dots, v^{-1}] = (-1)^{ab} d_A(x, y) [t^{l-1}, \dots, t^a, u^{-1}t^{a-1}, \dots, u^{-1}].$$

Hence by the admissible relations for the symbols $[x_1, \dots, x_l]$ we see that

$$d_A(x, y) = (-1)^{ab} u^a / v^b \bmod \mathfrak{m}_A$$

as desired. \square

We add the following lemma here. It is very similar to Algebra, Lemma 10.115.2.

Lemma 41.4.11. *Let R be a local Noetherian domain of dimension 1 with maximal ideal \mathfrak{m} . Let $a, b \in \mathfrak{m}$ be nonzero. There exists a finite ring extension $R \subset R'$ with same field of fractions, and $t, a', b' \in R'$ such that $a = ta'$ and $b = tb'$ and $R' = a'R' + b'R'$.*

Proof. Set $I = (a, b)$. The idea is to blow up R in I as in the proof of Algebra, Lemma 10.115.2. Instead of doing the algebraic argument we work geometrically. Let $X = \text{Proj}(\bigoplus I^d/I^{d+1})$. By Divisors, Lemma 30.18.7 this is an integral scheme. The morphism $X \rightarrow \text{Spec}(R)$ is projective by Divisors, Lemma 30.18.11. By Algebra, Lemma 10.109.2 and the fact that X is quasi-compact we see that the fibre of $X \rightarrow \text{Spec}(R)$ over \mathfrak{m} is finite. By Properties, Lemma 27.27.5 there exists an affine open $U \subset X$ containing this fibre. Hence $X = U$ because $X \rightarrow \text{Spec}(R)$ is closed. In other words X is affine, say $X = \text{Spec}(R')$. By Morphisms, Lemma 28.16.2 we see that $R \rightarrow R'$ is of finite type. Since $X \rightarrow \text{Spec}(R)$ is proper and affine it is integral (see Morphisms, Lemma 28.44.7). Hence $R \rightarrow R'$ is of finite type and integral, hence finite (Algebra, Lemma 10.35.5). By Divisors, Lemma 30.18.4 we see that IR' is a locally principal ideal. Since R' is semi-local we see that IR' is principal, see Algebra, Lemma 10.75.6, say $IR' = (t)$. Then we have $a = a't$ and $b = b't$ and everything is clear. \square

Lemma 41.4.12. *Let A be a Noetherian local ring. Let $a, b \in A$. Let M be a finite A -module of dimension 1 on which each of $a, b, b - a$ are nonzerodivisors. Then*

$$d_M(a, b - a)d_M(b, b) = d_M(b, b - a)d_M(a, b)$$

in κ^* .

Proof. By Lemma 41.4.9 it suffices to show the relation when $M = A/\mathfrak{q}$ for some prime $\mathfrak{q} \subset A$ with $\dim(A/\mathfrak{q}) = 1$.

In case $M = A/\mathfrak{q}$ we may replace A by A/\mathfrak{q} and a, b by their images in A/\mathfrak{q} . Hence we may assume $A = M$ and A a local Noetherian domain of dimension 1. The reason is that the residue field κ of A and A/\mathfrak{q} are the same and that for any A/\mathfrak{q} -module M the determinant taken over A or over A/\mathfrak{q} are canonically identified. See Lemma 41.2.7.

It suffices to show the relation when both a, b are in the maximal ideal. Namely, the case where one or both are units follows from Lemma 41.4.6.

Choose an extension $A \subset A'$ and factorizations $a = ta', b = tb'$ as in Lemma 41.4.11. Note that also $b - a = t(b' - a')$ and that $A' = (a', b') = (a', b' - a') = (b' - a', b')$. Here and in the following we think of A' as an A -module and a, b, a', b', t as A -module endomorphisms of A' . We will use the notation $d_{A'}^A(a', b')$ and so on to indicate

$$d_{A'}^A(a', b') = \det_{\kappa}(A'/a'b'A', a', b')$$

which is defined by Lemma 41.4.1. The upper index A is used to distinguish this from the already defined symbol $d_{A'}(a', b')$ which is different (for example because it has values in the residue field of A' which may be different from κ). By Lemma 41.4.8 we see that $d_A(a, b) = d_{A'}^A(a, b)$, and similarly for the other combinations. Using this and multiplicativity we see that it suffices to prove

$$d_{A'}^A(a', b' - a')d_{A'}^A(b', b') = d_{A'}^A(b', b' - a')d_{A'}^A(a', b')$$

Now, since $(a', b') = A'$ and so on we have

$$\begin{aligned} A'/(a'(b' - a')) &\cong A'/(a') \oplus A'/(b' - a') \\ A'/(b'(b' - a')) &\cong A'/(b') \oplus A'/(b' - a') \\ A'/(a'b') &\cong A'/(a') \oplus A'/(b') \end{aligned}$$

Moreover, note that multiplication by $b' - a'$ on $A/(a')$ is equal to multiplication by b' , and that multiplication by $b' - a'$ on $A/(b')$ is equal to multiplication by $-a'$. Using Lemmas 41.3.8 and 41.3.9 we conclude

$$\begin{aligned} d_{A'}^A(a', b' - a') &= \det_{\kappa}(b'|_{A'/(a')})^{-1} \det_{\kappa}(a'|_{A'/(b'-a')}) \\ d_{A'}^A(b', b' - a') &= \det_{\kappa}(-a'|_{A'/(b')})^{-1} \det_{\kappa}(b'|_{A'/(b'-a')}) \\ d_{A'}^A(a', b') &= \det_{\kappa}(b'|_{A'/(a')})^{-1} \det_{\kappa}(a'|_{A'/(b')}) \end{aligned}$$

Hence we conclude that

$$(-1)^{\text{length}_A(A'/(b'))} d_{A'}^A(a', b' - a') = d_{A'}^A(b', b' - a') d_{A'}^A(a', b')$$

the sign coming from the $-a'$ in the second equality above. On the other hand, by Lemma 41.3.7 we have $d_{A'}^A(b', b') = (-1)^{\text{length}_A(A'/(b'))}$, and the lemma is proved. \square

The tame symbol is a Steinberg symbol.

Lemma 41.4.13. *Let A be a Noetherian local domain of dimension 1. Let $K = f.f.(A)$. For $x \in K \setminus \{0, 1\}$ we have*

$$d_A(x, 1 - x) = 1$$

Proof. Write $x = a/b$ with $a, b \in A$. The hypothesis implies, since $1 - x = (b - a)/b$, that also $b - a \neq 0$. Hence we compute

$$d_A(x, 1 - x) = d_A(a, b - a) d_A(a, b)^{-1} d_A(b, b - a)^{-1} d_A(b, b)$$

Thus we have to show that $d_A(a, b - a) d_A(b, b) = d_A(b, b - a) d_A(a, b)$. This is Lemma 41.4.12. \square

41.5. Lengths and determinants

In this section we use the determinant to compare lattices. The key lemma is the following.

Lemma 41.5.1. *Let R be a noetherian local ring. Let $\mathfrak{q} \subset R$ be a prime with $\dim(R/\mathfrak{q}) = 1$. Let $\varphi : M \rightarrow N$ be a homomorphism of finite R -modules. Assume there exist $x_1, \dots, x_l \in M$ and $y_1, \dots, y_l \in M$ with the following properties*

- (1) $M = \langle x_1, \dots, x_l \rangle$,
- (2) $\langle x_1, \dots, x_i \rangle / \langle x_1, \dots, x_{i-1} \rangle \cong R/\mathfrak{q}$ for $i = 1, \dots, l$,
- (3) $N = \langle y_1, \dots, y_l \rangle$, and
- (4) $\langle y_1, \dots, y_i \rangle / \langle y_1, \dots, y_{i-1} \rangle \cong R/\mathfrak{q}$ for $i = 1, \dots, l$.

Then φ is injective if and only if $\varphi_{\mathfrak{q}}$ is an isomorphism, and in this case we have

$$\text{length}_R(\text{Coker}(\varphi)) = \text{ord}_{R/\mathfrak{q}}(f)$$

where $f \in \kappa(\mathfrak{q})$ is the element such that

$$[\varphi(x_1), \dots, \varphi(x_l)] = f[y_1, \dots, y_l]$$

in $\det_{\kappa(\mathfrak{q})}(N_{\mathfrak{q}})$.

Proof. First, note that the lemma holds in case $l = 1$. Namely, in this case x_1 is a basis of M over R/\mathfrak{q} and y_1 is a basis of N over R/\mathfrak{q} and we have $\varphi(x_1) = f y_1$ for some $f \in R$. Thus φ is injective if and only if $f \notin \mathfrak{q}$. Moreover, $\text{Coker}(\varphi) = R/(f, \mathfrak{q})$ and hence the lemma holds by definition of $\text{ord}_{R/\mathfrak{q}}(f)$ (see Algebra, Definition 10.117.2).

In fact, suppose more generally that $\varphi(x_i) = f_i y_i$ for some $f_i \in R$, $f_i \notin \mathfrak{q}$. Then the induced maps

$$\langle x_1, \dots, x_i \rangle / \langle x_1, \dots, x_{i-1} \rangle \longrightarrow \langle y_1, \dots, y_i \rangle / \langle y_1, \dots, y_{i-1} \rangle$$

are all injective and have cokernels isomorphic to $R/(f_i, \mathfrak{q})$. Hence we see that

$$\text{length}_R(\text{Coker}(\varphi)) = \sum \text{ord}_{R/\mathfrak{q}}(f_i).$$

On the other hand it is clear that

$$[\varphi(x_1), \dots, \varphi(x_l)] = f_1 \dots f_l [y_1, \dots, y_l]$$

in this case from the admissible relation (b) for symbols. Hence we see the result holds in this case also.

We prove the general case by induction on l . Assume $l > 1$. Let $i \in \{1, \dots, l\}$ be minimal such that $\varphi(x_1) \in \langle y_1, \dots, y_i \rangle$. We will argue by induction on i . If $i = 1$, then we get a commutative diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \langle x_1 \rangle & \longrightarrow & \langle x_1, \dots, x_i \rangle & \longrightarrow & \langle x_1, \dots, x_i \rangle / \langle x_1 \rangle \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & \langle y_1 \rangle & \longrightarrow & \langle y_1, \dots, y_i \rangle & \longrightarrow & \langle y_1, \dots, y_i \rangle / \langle y_1 \rangle \longrightarrow 0 \end{array}$$

and the lemma follows from the snake lemma and induction on l . Assume now that $i > 1$. Write $\varphi(x_1) = a_1 y_1 + \dots + a_{i-1} y_{i-1} + a y_i$ with $a_j, a \in R$ and $a \notin \mathfrak{q}$ (since otherwise i was not minimal). Set

$$x'_j = \begin{cases} x_j & \text{if } j = 1 \\ ax_j & \text{if } j \geq 2 \end{cases} \quad \text{and} \quad y'_j = \begin{cases} y_j & \text{if } j < i \\ ay_j & \text{if } j \geq i \end{cases}$$

Let $M' = \langle x'_1, \dots, x'_l \rangle$ and $N' = \langle y'_1, \dots, y'_l \rangle$. Since $\varphi(x'_1) = a_1 y'_1 + \dots + a_{i-1} y'_{i-1} + y'_i$ by construction and since for $j > 1$ we have $\varphi(x'_j) = a \varphi(x_j) \in \langle y'_1, \dots, y'_l \rangle$ we get a commutative diagram of R -modules and maps

$$\begin{array}{ccc} M' & \xrightarrow{\varphi'} & N' \\ \downarrow & & \downarrow \\ M & \xrightarrow{\varphi} & N \end{array}$$

By the result of the second paragraph of the proof we know that $\text{length}_R(M/M') = (l-1)\text{ord}_{R/\mathfrak{q}}(a)$ and similarly $\text{length}_R(M/M') = (l-i+1)\text{ord}_{R/\mathfrak{q}}(a)$. By a diagram chase this implies that

$$\text{length}_R(\text{Coker}(\varphi')) = \text{length}_R(\text{Coker}(\varphi)) + i \text{ord}_{R/\mathfrak{q}}(a).$$

On the other hand, it is clear that writing

$$[\varphi(x_1), \dots, \varphi(x_l)] = f[y_1, \dots, y_l], \quad [\varphi'(x'_1), \dots, \varphi'(x'_l)] = f'[y'_1, \dots, y'_l]$$

we have $f' = a^i f$. Hence it suffices to prove the lemma for the case that $\varphi(x_1) = a_1 y_1 + \dots + a_{i-1} y_{i-1} + y_i$, i.e., in the case that $a = 1$. Next, recall that

$$[y_1, \dots, y_l] = [y_1, \dots, y_{i-1}, a_1 y_1 + \dots + a_{i-1} y_{i-1} + y_i, y_{i+1}, \dots, y_l]$$

by the admissible relations for symbols. The sequence $y_1, \dots, y_{i-1}, a_1 y_1 + \dots + a_{i-1} y_{i-1} + y_i, y_{i+1}, \dots, y_l$ satisfies the conditions (3), (4) of the lemma also. Hence,

we may actually assume that $\varphi(x_1) = y_i$. In this case, note that we have $\mathfrak{q}x_1 = 0$ which implies also $\mathfrak{q}y_i = 0$. We have

$$[y_1, \dots, y_l] = -[y_1, \dots, y_{i-2}, y_i, y_{i-1}, y_{i+1}, \dots, y_l]$$

by the third of the admissible relations defining $\det_{\kappa(\mathfrak{q})}(N_{\mathfrak{q}})$. Hence we may replace y_1, \dots, y_l by the sequence $y'_1, \dots, y'_l = y_1, \dots, y_{i-2}, y_i, y_{i-1}, y_{i+1}, \dots, y_l$ (which also satisfies conditions (3) and (4) of the lemma). Clearly this decreases the invariant i by 1 and we win by induction on i . \square

To use the previous lemma we show that often sequences of elements with the required properties exist.

Lemma 41.5.2. *Let R be a local Noetherian ring. Let $\mathfrak{q} \subset R$ be a prime ideal. Let M be a finite R -module such that \mathfrak{q} is one of the minimal primes of the support of M . Then there exist $x_1, \dots, x_l \in M$ such that*

- (1) *the support of $M/\langle x_1, \dots, x_l \rangle$ does not contain \mathfrak{q} , and*
- (2) *$\langle x_1, \dots, x_i \rangle / \langle x_1, \dots, x_{i-1} \rangle \cong R/\mathfrak{q}$ for $i = 1, \dots, l$.*

Moreover, in this case $l = \text{length}_{R_{\mathfrak{q}}}(M_{\mathfrak{q}})$.

Proof. The condition that \mathfrak{q} is a minimal prime in the support of M implies that $l = \text{length}_{R_{\mathfrak{q}}}(M_{\mathfrak{q}})$ is finite (see Algebra, Lemma 10.61.3). Hence we can find $y_1, \dots, y_l \in M_{\mathfrak{q}}$ such that $\langle y_1, \dots, y_i \rangle / \langle y_1, \dots, y_{i-1} \rangle \cong \kappa(\mathfrak{q})$ for $i = 1, \dots, l$. We can find $f_i \in R$, $f_i \notin \mathfrak{q}$ such that $f_i y_i$ is the image of some element $z_i \in M$. Moreover, as R is Noetherian we can write $\mathfrak{q} = (g_1, \dots, g_t)$ for some $g_j \in R$. By assumption $g_j y_i \in \langle y_1, \dots, y_{i-1} \rangle$ inside the module $M_{\mathfrak{q}}$. By our choice of z_i we can find some further elements $f_{ji} \in R$, $f_{ji} \notin \mathfrak{q}$ such that $f_{ij} g_j z_i \in \langle z_1, \dots, z_{i-1} \rangle$ (equality in the module M). The lemma follows by taking

$$x_1 = f_{11} f_{12} \dots f_{1t} z_1, \quad x_2 = f_{11} f_{12} \dots f_{1t} f_{21} f_{22} \dots f_{2t} z_2,$$

and so on. Namely, since all the elements f_i, f_{ij} are invertible in $R_{\mathfrak{q}}$ we still have that $R_{\mathfrak{q}} x_1 + \dots + R_{\mathfrak{q}} x_i / R_{\mathfrak{q}} x_1 + \dots + R_{\mathfrak{q}} x_{i-1} \cong \kappa(\mathfrak{q})$ for $i = 1, \dots, l$. By construction, $\mathfrak{q} x_i \in \langle x_1, \dots, x_{i-1} \rangle$. Thus $\langle x_1, \dots, x_i \rangle / \langle x_1, \dots, x_{i-1} \rangle$ is an R -module generated by one element, annihilated \mathfrak{q} such that localizing at \mathfrak{q} gives a q -dimensional vector space over $\kappa(\mathfrak{q})$. Hence it is isomorphic to R/\mathfrak{q} . \square

Here is the main result of this section. We will see below the various different consequences of this proposition. The reader is encouraged to first prove the easier Lemma 41.5.4 his/herself.

Proposition 41.5.3. *Let R be a local Noetherian ring with residue field κ . Suppose that (M, φ, ψ) is a $(2, 1)$ -periodic complex over R . Assume*

- (1) *M is a finite R -module,*
- (2) *the cohomology modules of (M, φ, ψ) are of finite length, and*
- (3) *$\dim(\text{Supp}(M)) = 1$.*

Let \mathfrak{q}_i , $i = 1, \dots, t$ be the minimal primes of the support of M . Then we have²

$$-e_R(M, \varphi, \psi) = \sum_{i=1, \dots, t} \text{ord}_{R/\mathfrak{q}_i} (\det_{\kappa(\mathfrak{q}_i)}(M_{\mathfrak{q}_i}, \varphi_{\mathfrak{q}_i}, \psi_{\mathfrak{q}_i}))$$

² Obviously we could get rid of the minus sign by redefining $\det_{\kappa}(M, \varphi, \psi)$ as the inverse of its current value, see Definition 41.3.4.

Proof. We first reduce to the case $t = 1$ in the following way. Note that $\text{Supp}(M) = \{\mathfrak{m}, \mathfrak{q}_1, \dots, \mathfrak{q}_t\}$, where $\mathfrak{m} \subset R$ is the maximal ideal. Let M_i denote the image of $M \rightarrow M_{\mathfrak{q}_i}$, so $\text{Supp}(M_i) = \{\mathfrak{m}, \mathfrak{q}_i\}$. The map φ (resp. ψ) induces an R -module map $\varphi_i : M_i \rightarrow M_i$ (resp. $\psi_i : M_i \rightarrow M_i$). Thus we get a morphism of $(2, 1)$ -periodic complexes

$$(M, \varphi, \psi) \longrightarrow \bigoplus_{i=1, \dots, t} (M_i, \varphi_i, \psi_i).$$

The kernel and cokernel of this map have support equal to $\{\mathfrak{m}\}$ (or are zero). Hence by Lemma 41.3.3 these $(2, 1)$ -periodic complexes have multiplicity 0. In other words we have

$$e_R(M, \varphi, \psi) = \sum_{i=1, \dots, t} e_R(M_i, \varphi_i, \psi_i)$$

On the other hand we clearly have $M_{\mathfrak{q}_i} = M_{i, \mathfrak{q}_i}$, and hence the terms of the right hand side of the formula of the lemma are equal to the expressions

$$\text{ord}_{R/\mathfrak{q}_i} (\det_{\kappa(\mathfrak{q}_i)}(M_{i, \mathfrak{q}_i}, \varphi_{i, \mathfrak{q}_i}, \psi_{i, \mathfrak{q}_i}))$$

In other words, if we can prove the lemma for each of the modules M_i , then the lemma holds. This reduces us to the case $t = 1$.

Assume we have a $(2, 1)$ -periodic complex (M, φ, ψ) over a Noetherian local ring with M a finite R -module, $\text{Supp}(M) = \{\mathfrak{m}, \mathfrak{q}\}$, and finite length cohomology modules. The proof in this case follows from Lemma 41.5.1 and careful bookkeeping. Denote $K_\varphi = \text{Ker}(\varphi)$, $I_\varphi = \text{Im}(\varphi)$, $K_\psi = \text{Ker}(\psi)$, and $I_\psi = \text{Im}(\psi)$. Since R is Noetherian these are all finite R -modules. Set

$$a = \text{length}_{R_{\mathfrak{q}}}(I_{\varphi, \mathfrak{q}}) = \text{length}_{R_{\mathfrak{q}}}(K_{\psi, \mathfrak{q}}), \quad b = \text{length}_{R_{\mathfrak{q}}}(I_{\psi, \mathfrak{q}}) = \text{length}_{R_{\mathfrak{q}}}(K_{\varphi, \mathfrak{q}}).$$

Equalities because the complex becomes exact after localizing at \mathfrak{q} . Note that $l = \text{length}_{R_{\mathfrak{q}}}(M_{\mathfrak{q}})$ is equal to $l = a + b$.

We are going to use Lemma 41.5.2 to choose sequences of elements in finite R -modules N with support contained in $\{\mathfrak{m}, \mathfrak{q}\}$. In this case $N_{\mathfrak{q}}$ has finite length, say $n \in \mathbf{N}$. Let us call a sequence $w_1, \dots, w_n \in N$ with properties (1) and (2) of Lemma 41.5.2 a “good sequence”. Note that the quotient $N/\langle w_1, \dots, w_n \rangle$ of N by the submodule generated by a good sequence has support (contained in) $\{\mathfrak{m}\}$ and hence has finite length (Algebra, Lemma 10.61.3). Moreover, the symbol $[w_1, \dots, w_n] \in \det_{\kappa(\mathfrak{q})}(N_{\mathfrak{q}})$ is a generator, see Lemma 41.2.4.

Having said this we choose good sequences

$$\begin{array}{ll} x_1, \dots, x_b & \text{in } K_\varphi, & t_1, \dots, t_a & \text{in } K_\psi, \\ y_1, \dots, y_a & \text{in } I_\varphi \cap \langle t_1, \dots, t_a \rangle, & s_1, \dots, s_b & \text{in } I_\psi \cap \langle x_1, \dots, x_b \rangle. \end{array}$$

We will adjust our choices a little bit as follows. Choose lifts $\tilde{y}_i \in M$ of $y_i \in I_\varphi$ and $\tilde{s}_i \in M$ of $s_i \in I_\psi$. It may not be the case that $\mathfrak{q}\tilde{y}_1 \subset \langle x_1, \dots, x_b \rangle$ and it may not be the case that $\mathfrak{q}\tilde{s}_1 \subset \langle t_1, \dots, t_a \rangle$. However, using that \mathfrak{q} is finitely generated (as in the proof of Lemma 41.5.2) we can find a $d \in R$, $d \notin \mathfrak{q}$ such that $\mathfrak{q}d\tilde{y}_1 \subset \langle x_1, \dots, x_b \rangle$ and $\mathfrak{q}d\tilde{s}_1 \subset \langle t_1, \dots, t_a \rangle$. Thus after replacing y_i by dy_i , \tilde{y}_i by $d\tilde{y}_i$, s_i by ds_i and \tilde{s}_i by $d\tilde{s}_i$ we see that we may assume also that $x_1, \dots, x_b, \tilde{y}_1, \dots, \tilde{y}_a$ and $t_1, \dots, t_a, \tilde{s}_1, \dots, \tilde{s}_b$ are good sequences in M .

Finally, we choose a good sequence z_1, \dots, z_l in the finite R -module

$$\langle x_1, \dots, x_b, \tilde{y}_1, \dots, \tilde{y}_a \rangle \cap \langle t_1, \dots, t_a, \tilde{s}_1, \dots, \tilde{s}_b \rangle.$$

Note that this is also a good sequence in M .

Since $I_{\varphi, \mathfrak{q}} = K_{\psi, \mathfrak{q}}$ there is a unique element $h \in \kappa(\mathfrak{q})$ such that $[y_1, \dots, y_a] = h[t_1, \dots, t_a]$ inside $\det_{\kappa(\mathfrak{q})}(K_{\psi, \mathfrak{q}})$. Similarly, as $I_{\psi, \mathfrak{q}} = K_{\varphi, \mathfrak{q}}$ there is a unique element $h \in \kappa(\mathfrak{q})$ such that $[s_1, \dots, s_b] = g[x_1, \dots, x_b]$ inside $\det_{\kappa(\mathfrak{q})}(K_{\varphi, \mathfrak{q}})$. We can also do this with the three good sequences we have in M . All in all we get the following identities

$$\begin{aligned} [y_1, \dots, y_a] &= h[t_1, \dots, t_a] \\ [s_1, \dots, s_b] &= g[x_1, \dots, x_b] \\ [z_1, \dots, z_l] &= f_{\varphi}[x_1, \dots, x_b, \tilde{y}_1, \dots, \tilde{y}_a] \\ [z_1, \dots, z_l] &= f_{\psi}[t_1, \dots, t_a, \tilde{s}_1, \dots, \tilde{s}_b] \end{aligned}$$

for some $g, h, f_{\varphi}, f_{\psi} \in \kappa(\mathfrak{q})$.

Having set up all this notation let us compute $\det_{\kappa(\mathfrak{q})}(M, \varphi, \psi)$. Namely, consider the element $[z_1, \dots, z_l]$. Under the map $\gamma_{\psi} \circ \sigma \circ \gamma_{\varphi}^{-1}$ of Definition 41.3.4 we have

$$\begin{aligned} [z_1, \dots, z_l] &= f_{\varphi}[x_1, \dots, x_b, \tilde{y}_1, \dots, \tilde{y}_a] \\ &\mapsto f_{\varphi}[x_1, \dots, x_b] \otimes [y_1, \dots, y_a] \\ &\mapsto f_{\varphi}h/g[t_1, \dots, t_a] \otimes [s_1, \dots, s_b] \\ &\mapsto f_{\varphi}h/g[t_1, \dots, t_a, \tilde{s}_1, \dots, \tilde{s}_b] \\ &= f_{\varphi}h/f_{\psi}g[z_1, \dots, z_l] \end{aligned}$$

This means that $\det_{\kappa(\mathfrak{q})}(M_{\mathfrak{q}}, \varphi_{\mathfrak{q}}, \psi_{\mathfrak{q}})$ is equal to $f_{\varphi}h/f_{\psi}g$ up to a sign.

We abbreviate the following quantities

$$\begin{aligned} k_{\varphi} &= \text{length}_R(K_{\varphi}/\langle x_1, \dots, x_b \rangle) \\ k_{\psi} &= \text{length}_R(K_{\psi}/\langle t_1, \dots, t_a \rangle) \\ i_{\varphi} &= \text{length}_R(I_{\varphi}/\langle y_1, \dots, y_a \rangle) \\ i_{\psi} &= \text{length}_R(I_{\psi}/\langle s_1, \dots, s_b \rangle) \\ m_{\varphi} &= \text{length}_R(M/\langle x_1, \dots, x_b, \tilde{y}_1, \dots, \tilde{y}_a \rangle) \\ m_{\psi} &= \text{length}_R(M/\langle t_1, \dots, t_a, \tilde{s}_1, \dots, \tilde{s}_b \rangle) \\ \delta_{\varphi} &= \text{length}_R(\langle x_1, \dots, x_b, \tilde{y}_1, \dots, \tilde{y}_a \rangle \langle z_1, \dots, z_l \rangle) \\ \delta_{\psi} &= \text{length}_R(\langle t_1, \dots, t_a, \tilde{s}_1, \dots, \tilde{s}_b \rangle \langle z_1, \dots, z_l \rangle) \end{aligned}$$

Using the exact sequences $0 \rightarrow K_{\varphi} \rightarrow M \rightarrow I_{\varphi} \rightarrow 0$ we get $m_{\varphi} = k_{\varphi} + i_{\varphi}$. Similarly we have $m_{\psi} = k_{\psi} + i_{\psi}$. We have $\delta_{\varphi} + m_{\varphi} = \delta_{\psi} + m_{\psi}$ since this is equal to the colength of $\langle z_1, \dots, z_l \rangle$ in M . Finally, we have

$$\delta_{\varphi} = \text{ord}_{R/\mathfrak{q}}(f_{\varphi}), \quad \delta_{\psi} = \text{ord}_{R/\mathfrak{q}}(f_{\psi})$$

by our first application of the key Lemma 41.5.1.

Next, let us compute the multiplicity of the periodic complex

$$\begin{aligned}
 e_R(M, \varphi, \psi) &= \text{length}_R(K_\varphi/I_\psi) - \text{length}_R(K_\psi/I_\varphi) \\
 &= \text{length}_R(\langle x_1, \dots, x_b \rangle / \langle s_1, \dots, s_b \rangle) + k_\varphi - i_\psi \\
 &\quad - \text{length}_R(\langle t_1, \dots, t_a \rangle / \langle y_1, \dots, y_a \rangle) - k_\psi + i_\varphi \\
 &= \text{ord}_{R/\mathfrak{q}}(g/h) + k_\varphi - i_\psi - k_\psi + i_\varphi \\
 &= \text{ord}_{R/\mathfrak{q}}(g/h) + m_\varphi - m_\psi \\
 &= \text{ord}_{R/\mathfrak{q}}(g/h) + \delta_\psi - \delta_\varphi \\
 &= \text{ord}_{R/\mathfrak{q}}(f_\psi g / f_\varphi h)
 \end{aligned}$$

where we used the key Lemma 41.5.1 twice in the third equality. By our computation of $\det_{\kappa(\mathfrak{q})}(M_{\mathfrak{q}}, \varphi_{\mathfrak{q}}, \psi_{\mathfrak{q}})$ this proves the proposition. \square

In most applications the following lemma suffices.

Lemma 41.5.4. *Let R be a Noetherian local ring with maximal ideal \mathfrak{m} . Let M be a finite R -module, and let $\psi : M \rightarrow M$ be an R -module map. Assume that*

- (1) $\text{Ker}(\psi)$ and $\text{Coker}(\psi)$ have finite length, and
- (2) $\dim(\text{Supp}(M)) \leq 1$.

Write $\text{Supp}(M) = \{\mathfrak{m}, \mathfrak{q}_1, \dots, \mathfrak{q}_t\}$ and denote $f_i \in \kappa(\mathfrak{q}_i)^*$ the element such that $\det_{\kappa(\mathfrak{q}_i)}(\psi_{\mathfrak{q}_i}) : \det_{\kappa(\mathfrak{q}_i)}(M_{\mathfrak{q}_i}) \rightarrow \det_{\kappa(\mathfrak{q}_i)}(M_{\mathfrak{q}_i})$ is multiplication by f_i . Then we have

$$\text{length}_R(\text{Coker}(\psi)) - \text{length}_R(\text{Ker}(\psi)) = \sum_{i=1, \dots, t} \text{ord}_{R/\mathfrak{q}_i}(f_i).$$

Proof. Recall that $H^0(M, 0, \psi) = \text{Coker}(\psi)$ and $H^1(M, 0, \psi) = \text{Ker}(\psi)$, see remarks above Definition 41.3.2. The lemma follows by combining Proposition 41.5.3 with Lemma 41.3.8.

Alternative proof. Reduce to the case $\text{Supp}(M) = \{\mathfrak{m}, \mathfrak{q}\}$ as in the proof of Proposition 41.5.3. Then directly combine Lemmas 41.5.1 and 41.5.2 to prove this specific case of Proposition 41.5.3. There is much less bookkeeping in this case, and the reader is encouraged to work this out. Details omitted. \square

Lemma 41.5.5. *Let R be a Noetherian local ring with maximal ideal \mathfrak{m} . Let M be a finite R -module. Let $x \in R$. Assume that*

- (1) $\dim(\text{Supp}(M)) \leq 1$, and
- (2) $\dim(M/xM) \leq 0$.

Write $\text{Supp}(M) = \{\mathfrak{m}, \mathfrak{q}_1, \dots, \mathfrak{q}_t\}$. Then

$$\text{length}_R(M_x) - \text{length}_R(xM) = \sum_{i=1, \dots, t} \text{ord}_{R/\mathfrak{q}_i}(x) \text{length}_{R/\mathfrak{q}_i}(M_{\mathfrak{q}_i}).$$

where $M_x = M/xM$ and ${}_xM = \text{Ker}(x : M \rightarrow M)$.

Proof. This is a special case of Lemma 41.5.4. To see that $f_i = x^{\text{length}_{R/\mathfrak{q}_i}(M_{\mathfrak{q}_i})}$ see Lemma 41.2.8. \square

Lemma 41.5.6. *Let R be a Noetherian local ring with maximal ideal \mathfrak{m} . Let $I \subset R$ be an ideal and let $x \in R$. Assume x is a nonzerodivisor on R/I and that $\dim(R/I) = 1$. Then*

$$\text{length}_R(R/(x, I)) = \sum_i \text{length}_R(R/(x, \mathfrak{q}_i)) \text{length}_{R/\mathfrak{q}_i}((R/I)_{\mathfrak{q}_i})$$

where $\mathfrak{q}_1, \dots, \mathfrak{q}_n$ are the minimal primes over I . More generally if M is any finite Cohen-Macaulay module of dimension 1 over R and $\dim(M/xM) = 0$, then

$$\text{length}_R(M/xM) = \sum_i \text{length}_R(R/(x, \mathfrak{q}_i)) \text{length}_{R_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}).$$

where $\mathfrak{q}_1, \dots, \mathfrak{q}_t$ are the minimal primes of the support of M .

Proof. These are special cases of Lemma 41.5.5. □

Lemma 41.5.7. *Let A be a Noetherian local ring. Let M be a finite A -module. Let $a, b \in A$. Assume*

- (1) $\dim(A) = 1$,
- (2) both a and b are nonzerodivisors in A ,
- (3) A has no embedded primes,
- (4) M has no embedded associated primes,
- (5) $\text{Supp}(M) = \text{Spec}(A)$.

Let $I = \{x \in A \mid x(a/b) \in A\}$. Let $\mathfrak{q}_1, \dots, \mathfrak{q}_t$ be the minimal primes of A . Then $(a/b)IM \subset M$ and

$$\text{length}_A(M/(a/b)IM) - \text{length}_A(M/IM) = \sum_i \text{length}_{A_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}) \text{ord}_{A/\mathfrak{q}_i}(a/b)$$

Proof. Since M has no embedded associated primes, and since the support of M is $\text{Spec}(A)$ we see that $\text{Ass}(M) = \{\mathfrak{q}_1, \dots, \mathfrak{q}_t\}$. Hence a, b are nonzerodivisors on M . Note that

$$\begin{aligned} &\text{length}_A(M/(a/b)IM) \\ &= \text{length}_A(bM/aIM) \\ &= \text{length}_A(M/aIM) - \text{length}_A(M/bM) \\ &= \text{length}_A(M/aM) + \text{length}_A(aM/aIM) - \text{length}_A(M/bM) \\ &= \text{length}_A(M/aM) + \text{length}_A(M/IM) - \text{length}_A(M/bM) \end{aligned}$$

as the injective map $b : M \rightarrow bM$ maps $(a/b)IM$ to aIM and the injective map $a : M \rightarrow aM$ maps IM to aIM . Hence the left hand side of the equation of the lemma is equal to

$$\text{length}_A(M/aM) - \text{length}_A(M/bM).$$

Applying the second formula of Lemma 41.5.6 with $x = a, b$ respectively and using Algebra, Definition 10.117.2 of the ord-functions we get the result. □

41.6. Application to tame symbol

In this section we apply the results above to show the following lemma.

Lemma 41.6.1. *Let A be a 2-dimensional Noetherian local domain. Let $K = f.f.(A)$. Let $f, g \in K^*$. Let $\mathfrak{q}_1, \dots, \mathfrak{q}_t$ be the height 1 primes \mathfrak{q} of A such that either f or g is not an element of $A_{\mathfrak{q}}^*$. Then we have*

$$\sum_{i=1, \dots, t} \text{ord}_{A/\mathfrak{q}_i}(d_{A_{\mathfrak{q}_i}}(f, g)) = 0$$

We can also write this as

$$\sum_{\text{height}(\mathfrak{q})=1} \text{ord}_{A/\mathfrak{q}}(d_{A_{\mathfrak{q}}}(f, g)) = 0$$

since at any height one prime \mathfrak{q} of A where $f, g \in A_{\mathfrak{q}}^*$ we have $d_{A_{\mathfrak{q}}}(f, g) = 1$ by Lemma 41.4.6.

Proof. Since the tame symbols $d_{A_q}(f, g)$ are additive (Lemma 41.4.4) and the order functions $\text{ord}_{A/q}$ are additive (Algebra, Lemma 10.117.1) it suffices to prove the formula when $f = a \in A$ and $g = b \in A$. In this case we see that we have to show

$$\sum_{\text{height}(\mathfrak{q})=1} \text{ord}_{A/q}(\det_{\kappa}(A_{\mathfrak{q}}/(ab), a, b)) = 0$$

By Proposition 41.5.3 this is equivalent to showing that

$$e_A(A/(ab), a, b) = 0.$$

Since the complex $A/(ab) \xrightarrow{a} A/(ab) \xrightarrow{b} A/(ab) \xrightarrow{a} A/(ab)$ is exact we win. \square

41.7. Setup

We will throughout work over a locally Noetherian universally catenary base S endowed with a dimension function δ . Although it is likely possible to generalize (parts of) the discussion in the chapter, it seems that this is a good first approximation. We usually do not assume our schemes are separated or quasi-compact. Many interesting algebraic stacks are non-separated and/or non-quasi-compact and this is a good case study to see how to develop a reasonable theory for those as well. In order to reference these hypotheses we give it a number.

Situation 41.7.1. Here S is a locally Noetherian, and universally catenary scheme. Moreover, we assume S is endowed with a dimension function $\delta : S \rightarrow \mathbf{Z}$.

See Morphisms, Definition 28.18.1 for the notion of a universally catenary scheme, and see Topology, Definition 5.19.1 for the notion of a dimension function. Recall that any locally Noetherian catenary scheme locally has a dimension function, see Properties, Lemma 27.11.3. Moreover, there are lots of schemes which are universally catenary, see Morphisms, Lemma 28.18.4.

Let (S, δ) be as in Situation 41.7.1. Any scheme X locally of finite type over S is locally Noetherian and catenary. In fact, X has a canonical dimension function

$$\delta = \delta_{X/S} : X \rightarrow \mathbf{Z}$$

associated to $(f : X \rightarrow S, \delta)$ given by the rule $\delta_{X/S}(x) = \delta(f(x)) + \text{trdeg}_{\kappa(f(x))} \kappa(x)$. See Morphisms, Lemma 28.31.2. Moreover, if $h : X \rightarrow Y$ is a morphism of schemes locally of finite type over S , and $x \in X$, $y = h(x)$, then obviously $\delta_{X/S}(x) = \delta_{Y/S}(y) + \text{trdeg}_{\kappa(y)} \kappa(x)$. We will freely use this function and its properties in the following.

Here are the basic examples of setups as above. In fact, the main interest lies in the case where the base is the spectrum of a field, or the case where the base is the spectrum of a Dedekind ring (e.g. \mathbf{Z} , or a discrete valuation ring).

Example 41.7.2. Here $S = \text{Spec}(k)$ and k is a field. We set $\delta(pt) = 0$ where pt indicates the unique point of S . The pair (S, δ) is an example of a situation as in Situation 41.7.1 by Morphisms, Lemma 28.18.4.

Example 41.7.3. Here $S = \text{Spec}(A)$, where A is a Noetherian domain of dimension 1. For example we could consider $A = \mathbf{Z}$. We set $\delta(\mathfrak{p}) = 0$ if \mathfrak{p} is a maximal ideal and $\delta(\mathfrak{p}) = 1$ if $\mathfrak{p} = (0)$ corresponds to the generic point. This is an example of Situation 41.7.1 by Morphisms, Lemma 28.18.4.

In good cases δ corresponds to the dimension function.

Lemma 41.7.4. *Let (S, δ) be as in Situation 41.7.1. Assume in addition S is a Jacobson scheme, and $\delta(s) = 0$ for every closed point s of S . Let X be locally of finite type over S . Let $Z \subset X$ be an integral closed subscheme and let $\xi \in Z$ be its generic point. The following integers are the same:*

- (1) $\delta_{X/S}(\xi)$,
- (2) $\dim(Z)$, and
- (3) $\dim(\mathcal{O}_{Z,z})$ where z is a closed point of Z .

Proof. Let $X \rightarrow S$, $\xi \in Z \subset X$ be as in the lemma. Since X is locally of finite type over S we see that X is Jacobson, see Morphisms, Lemma 28.17.9. Hence closed points of X are dense in every closed subset of Z and map to closed points of S . Hence given any chain of irreducible closed subsets of Z we can end it with a closed point of Z . It follows that $\dim(Z) = \sup_z (\dim(\mathcal{O}_{Z,z}))$ (see Properties, Lemma 27.11.4) where $z \in Z$ runs over the closed points of Z . Note that $\dim(\mathcal{O}_{Z,z}) = \delta(\xi) - \delta(z)$ by the properties of a dimension function. For each closed $z \in Z$ the field extension $\kappa(z) \supset \kappa(f(z))$ is finite, see Morphisms, Lemma 28.17.8. Hence $\delta_{X/S}(z) = \delta(f(z)) = 0$ for $z \in Z$ closed. It follows that all three integers are equal. \square

In the situation of the lemma above the value of δ at the generic point of a closed irreducible subset is the dimension of the irreducible closed subset. However, in general we cannot expect the equality to hold. For example if $S = \text{Spec}(\mathbf{C}[[t]])$ and $X = \text{Spec}(\mathbf{C}((t)))$ then we would get $\delta(x) = 1$ for the unique point of X , but $\dim(X) = 0$. Still we want to think of $\delta_{X/S}$ as giving the dimension of the irreducible closed subschemes. Thus we introduce the following terminology.

Definition 41.7.5. Let (S, δ) as in Situation 41.7.1. For any scheme X locally of finite type over S and any irreducible closed subset $Z \subset X$ we define

$$\dim_\delta(Z) = \delta(\xi)$$

where $\xi \in Z$ is the generic point of Z . We will call this the δ -dimension of Z . If Z is a closed subscheme of X , then we define $\dim_\delta(Z)$ as the supremum of the δ -dimensions of its irreducible components.

41.8. Cycles

Since we are not assuming our schemes are quasi-compact we have to be a little careful when defining cycles. We have to allow infinite sums because a rational function may have infinitely many poles for example. In any case, if X is quasi-compact then a cycle is a finite sum as usual.

Definition 41.8.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $k \in \mathbf{Z}$.

- (1) A collection of closed subschemes $\{Z_i\}_{i \in I}$ of X is said to be *locally finite* if for every quasi-compact open $U \subset X$ the set

$$\#\{i \in I \mid Z_i \cap U \neq \emptyset\}$$

is finite.

- (2) A *cycle on X* is a formal sum

$$\alpha = \sum n_Z [Z]$$

where the sum is over integral closed subschemes $Z \subset X$, each $n_Z \in \mathbf{Z}$, and the collection $\{Z; n_Z \neq 0\}$ is locally finite.

- (3) A k -cycle, on X is a cycle

$$\alpha = \sum n_Z [Z]$$

where $n_Z \neq 0 \Rightarrow \dim_\delta(Z) = k$.

- (4) The abelian group of all k -cycles on X is denoted $Z_k(X)$.

In other words, a k -cycle on X is a locally finite formal \mathbf{Z} -linear combination of integral closed subschemes of δ -dimension k . Addition of k -cycles $\alpha = \sum n_Z [Z]$ and $\beta = \sum m_Z [Z]$ is given by

$$\alpha + \beta = \sum (n_Z + m_Z) [Z],$$

i.e., by adding the coefficients.

41.9. Cycle associated to a closed subscheme

Lemma 41.9.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $Z \subset X$ be a closed subscheme.*

- (1) *The collection of irreducible components of Z is locally finite.*
- (2) *Let $Z' \subset Z$ be an irreducible component and let $\xi \in Z'$ be its generic point. Then*

$$\text{length}_{\mathcal{O}_{X, \xi}} \mathcal{O}_{Z, \xi} < \infty$$

- (3) *If $\dim_\delta(Z) \leq k$ and $\xi \in Z$ with $\delta(\xi) = k$, then ξ is a generic point of an irreducible component of Z .*

Proof. Let $U \subset X$ be a quasi-compact open subscheme. Then U is a Noetherian scheme, and hence has a Noetherian underlying topological space (Properties, Lemma 27.5.5). Hence every subspace is Noetherian and has finitely many irreducible components (see Topology, Lemma 5.8.2). This proves (1).

Let $Z' \subset Z$, $\xi \in Z'$ be as in (2). Then $\dim(\mathcal{O}_{Z, \xi}) = 0$ (for example by Properties, Lemma 27.11.4). Hence $\mathcal{O}_{Z, \xi}$ is Noetherian local ring of dimension zero, and hence has finite length over itself (see Algebra, Proposition 10.59.6). Hence, it also has finite length over $\mathcal{O}_{X, \xi}$, see Algebra, Lemma 10.50.12.

Assume $\xi \in Z$ and $\delta(\xi) = k$. Consider the closure $Z' = \overline{\{\xi\}}$. It is an irreducible closed subscheme with $\dim_\delta(Z') = k$ by definition. Since $\dim_\delta(Z) = k$ it must be an irreducible component of Z . Hence we see (3) holds. \square

Definition 41.9.2. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $Z \subset X$ be a closed subscheme.

- (1) For any irreducible component $Z' \subset Z$ with generic point ξ the integer $m_{Z', Z} = \text{length}_{\mathcal{O}_{X, \xi}} \mathcal{O}_{Z, \xi}$ (Lemma 41.9.1) is called the *multiplicity of Z' in Z* .
- (2) Assume $\dim_\delta(Z) \leq k$. The k -cycle associated to Z is

$$[Z]_k = \sum m_{Z', Z} [Z']$$

where the sum is over the irreducible components of Z of δ -dimension k . (This is a k -cycle by Lemma 41.9.1.)

It is important to note that we only define $[Z]_k$ if the δ -dimension of Z does not exceed k . In other words, by convention, if we write $[Z]_k$ then this implies that $\dim_\delta(Z) \leq k$.

41.10. Cycle associated to a coherent sheaf

Lemma 41.10.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{F} be a coherent \mathcal{O}_X -module.*

- (1) *The collection of irreducible components of the support of \mathcal{F} is locally finite.*
- (2) *Let $Z' \subset \text{Supp}(\mathcal{F})$ be an irreducible component and let $\xi \in Z'$ be its generic point. Then*

$$\text{length}_{\mathcal{O}_{X,\xi}} \mathcal{F}_\xi < \infty$$

- (3) *If $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$ and $\xi \in Z$ with $\delta(\xi) = k$, then ξ is a generic point of an irreducible component of $\text{Supp}(\mathcal{F})$.*

Proof. By Cohomology of Schemes, Lemma 29.9.7 the support Z of \mathcal{F} is a closed subset of X . We may think of Z as a reduced closed subscheme of X (Schemes, Lemma 25.12.4). Hence (1) and (3) follow immediately by applying Lemma 41.9.1 to $Z \subset X$.

Let $\xi \in Z'$ be as in (2). In this case for any specialization $\xi' \rightsquigarrow \xi$ in X we have $\mathcal{F}_{\xi'} = 0$. Recall that the non-maximal primes of $\mathcal{O}_{X,\xi}$ correspond to the points of X specializing to ξ (Schemes, Lemma 25.13.2). Hence \mathcal{F}_ξ is a finite $\mathcal{O}_{X,\xi}$ -module whose support is $\{\mathfrak{m}_\xi\}$. Hence it has finite length by Algebra, Lemma 10.61.3. \square

Definition 41.10.2. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{F} be a coherent \mathcal{O}_X -module.

- (1) For any irreducible component $Z' \subset \text{Supp}(\mathcal{F})$ with generic point ξ the integer $m_{Z',\mathcal{F}} = \text{length}_{\mathcal{O}_{X,\xi}} \mathcal{F}_\xi$ (Lemma 41.10.1) is called the *multiplicity of Z' in \mathcal{F}* .
- (2) Assume $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$. The *k -cycle associated to \mathcal{F}* is

$$[\mathcal{F}]_k = \sum m_{Z',\mathcal{F}} [Z']$$

where the sum is over the irreducible components of $\text{Supp}(\mathcal{F})$ of δ -dimension k . (This is a k -cycle by Lemma 41.10.1.)

It is important to note that we only define $[\mathcal{F}]_k$ if \mathcal{F} is coherent and the δ -dimension of $\text{Supp}(\mathcal{F})$ does not exceed k . In other words, by convention, if we write $[\mathcal{F}]_k$ then this implies that \mathcal{F} is coherent on X and $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$.

Lemma 41.10.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $Z \subset X$ be a closed subscheme. If $\dim_\delta(Z) \leq k$, then $[Z]_k = [\mathcal{O}_Z]_k$.*

Proof. This is because in this case the multiplicities $m_{Z',Z}$ and m_{Z',\mathcal{O}_Z} agree by definition. \square

Lemma 41.10.4. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $0 \rightarrow \mathcal{F} \rightarrow \mathcal{G} \rightarrow \mathcal{H} \rightarrow 0$ be a short exact sequence of coherent sheaves on X . Assume that the δ -dimension of the supports of \mathcal{F} , \mathcal{G} , and \mathcal{H} is $\leq k$. Then $[\mathcal{G}]_k = [\mathcal{F}]_k + [\mathcal{H}]_k$.*

Proof. Follows immediately from additivity of lengths, see Algebra, Lemma 10.50.3. \square

41.11. Preparation for proper pushforward

Lemma 41.11.1. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume X, Y integral and $\dim_\delta(X) = \dim_\delta(Y)$. Then either $f(X)$ is contained in a proper closed subscheme of Y , or f is dominant and the extension of function fields $R(Y) \subset R(X)$ is finite.*

Proof. The closure $\overline{f(X)} \subset Y$ is irreducible as X is irreducible (Topology, Lemmas 5.7.2 and 5.7.3). If $\overline{f(X)} \neq Y$, then we are done. If $\overline{f(X)} = Y$, then f is dominant and by Morphisms, Lemma 28.8.5 we see that the generic point η_Y of Y is in the image of f . Of course this implies that $f(\eta_X) = \eta_Y$, where $\eta_X \in X$ is the generic point of X . Since $\delta(\eta_X) = \delta(\eta_Y)$ we see that $R(Y) = \kappa(\eta_Y) \subset \kappa(\eta_X) = R(X)$ is an extension of transcendence degree 0. Hence $R(Y) \subset R(X)$ is a finite extension by Morphisms, Lemma 28.47.4 (which applies by Morphisms, Lemma 28.16.8). \square

Lemma 41.11.2. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume f is quasi-compact, and $\{Z_i\}_{i \in I}$ is a locally finite collection of closed subsets of X . Then $\{f(Z_i)\}_{i \in I}$ is a locally finite collection of closed subsets of Y .*

Proof. Let $V \subset Y$ be a quasi-compact open subset. Since f is quasi-compact the open $f^{-1}(V)$ is quasi-compact. Hence the set $\{i \in I \mid Z_i \cap f^{-1}(V) \neq \emptyset\}$ is finite by assumption (Definition 41.8.1). Since this is the same as the set

$$\{i \in I \mid f(Z_i) \cap V \neq \emptyset\} = \{i \in I \mid \overline{f(Z_i)} \cap V \neq \emptyset\}$$

the lemma is proved. \square

41.12. Proper pushforward

Definition 41.12.1. Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume f is proper.

- (1) Let $Z \subset X$ be an integral closed subscheme with $\dim_\delta(Z) = k$. We define

$$f_*[Z] = \begin{cases} 0 & \text{if } \dim_\delta(f(Z)) < k, \\ \deg(Z/f(Z))[f(Z)] & \text{if } \dim_\delta(f(Z)) = k. \end{cases}$$

Here we think of $f(Z) \subset Y$ as an integral closed subscheme. The degree of Z over $f(Z)$ is finite if $\dim_\delta(f(Z)) = \dim_\delta(Z)$ by Lemma 41.11.1.

- (2) Let $\alpha = \sum n_Z[Z]$ be a k -cycle on X . The *pushforward* of α as the sum

$$f_*\alpha = \sum n_Z f_*[Z]$$

where each $f_*[Z]$ is defined as above. The sum is locally finite by Lemma 41.11.2 above.

By definition the proper pushforward of cycles

$$f_* : Z_k(X) \longrightarrow Z_k(Y)$$

is a homomorphism of abelian groups. It turns $X \mapsto Z_k(X)$ into a covariant functor on the category of schemes locally of finite type over S with morphisms equal to proper morphisms.

Lemma 41.12.2. *Let (S, δ) be as in Situation 41.7.1. Let X, Y , and Z be locally of finite type over S . Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be proper morphisms. Then $g_* \circ f_* = (g \circ f)_*$ as maps $Z_k(X) \rightarrow Z_k(Z)$.*

Proof. Let $W \subset X$ be an integral closed subscheme of dimension k . Consider $W' = f(Z) \subset Y$ and $W'' = g(f(Z)) \subset Z$. Since f, g are proper we see that W' (resp. W'') is an integral closed subscheme of Y (resp. Z). We have to show that $g_*(f_*[W]) = (f \circ g)_*[W]$. If $\dim_\delta(W'') < k$, then both sides are zero. If $\dim_\delta(W'') = k$, then we see the induced morphisms

$$W \longrightarrow W' \longrightarrow W''$$

both satisfy the hypotheses of Lemma 41.11.1. Hence

$$g_*(f_*[W]) = \deg(W/W') \deg(W'/W'')[W''], \quad (f \circ g)_*[W] = \deg(W/W'')[W''].$$

Then we can apply Morphisms, Lemma 28.47.6 to conclude. □

Lemma 41.12.3. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume f is proper.*

(1) *Let $Z \subset X$ be a closed subscheme with $\dim_\delta(Z) \leq k$. Then*

$$f_*[Z]_k = [f_*\mathcal{O}_Z]_k.$$

(2) *Let \mathcal{F} be a coherent sheaf on X such that $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$. Then*

$$f_*[\mathcal{F}]_k = [f_*\mathcal{F}]_k.$$

Note that the statement makes sense since $f_\mathcal{F}$ and $f_*\mathcal{O}_Z$ are coherent \mathcal{O}_Y -modules by Cohomology of Schemes, Proposition 29.17.2.*

Proof. Part (1) follows from (2) and Lemma 41.10.3. Let \mathcal{F} be a coherent sheaf on X . Assume that $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$. By Cohomology of Schemes, Lemma 29.9.7 there exists a closed subscheme $i : Z \rightarrow X$ and a coherent \mathcal{O}_Z -module \mathcal{G} such that $i_*\mathcal{G} \cong \mathcal{F}$ and such that the support of \mathcal{F} is Z . Let $Z' \subset Y$ be the scheme theoretic image of $f|_Z : Z \rightarrow Y$. Consider the commutative diagram of schemes

$$\begin{array}{ccc} Z & \xrightarrow{\quad} & X \\ f|_Z \downarrow & & \downarrow f \\ Z' & \xrightarrow{\quad} & Y \end{array}$$

We have $f_*\mathcal{F} = f_*i_*\mathcal{G} = i'_*(f|_Z)_*\mathcal{G}$ by going around the diagram in two ways. Suppose we know the result holds for closed immersions and for $f|_Z$. Then we see that

$$f_*[\mathcal{F}]_k = f_*i_*[\mathcal{G}]_k = (i')_*(f|_Z)_*[\mathcal{G}]_k = (i')_*[(f|_Z)_*\mathcal{G}]_k = [(i')_*(f|_Z)_*\mathcal{G}]_k = [f_*\mathcal{F}]_k$$

as desired. The case of a closed immersion is straightforward (omitted). Note that $f|_Z : Z \rightarrow Z'$ is a dominant morphism (see Morphisms, Lemma 28.6.3). Thus we have reduced to the case where $\dim_\delta(X) \leq k$ and $f : X \rightarrow Y$ is proper and dominant.

Assume $\dim_\delta(X) \leq k$ and $f : X \rightarrow Y$ is proper and dominant. Since f is dominant, for every irreducible component $Z \subset Y$ with generic point η there exists a point $\xi \in X$ such that $f(\xi) = \eta$. Hence $\delta(\eta) \leq \delta(\xi) \leq k$. Thus we see that in the expressions

$$f_*[\mathcal{F}]_k = \sum n_Z[Z], \quad \text{and} \quad [f_*\mathcal{F}]_k = \sum m_Z[Z].$$

whenever $n_Z \neq 0$, or $m_Z \neq 0$ the integral closed subscheme Z is actually an irreducible component of Y of δ -dimension k . Pick such an integral closed subscheme $Z \subset Y$ and denote η its generic point. Note that for any $\xi \in X$ with $f(\xi) = \eta$ we

have $\delta(\xi) \geq k$ and hence ξ is a generic point of an irreducible component of X of δ -dimension k as well (see Lemma 41.9.1). Since f is quasi-compact and X is locally Noetherian, there can be only finitely many of these and hence $f^{-1}(\{\eta\})$ is finite. By Morphisms, Lemma 28.47.1 there exists an open neighbourhood $\eta \in V \subset Y$ such that $f^{-1}(V) \rightarrow V$ is finite. Replacing Y by V and X by $f^{-1}(V)$ we reduce to the case where Y is affine, and f is finite.

Write $Y = \text{Spec}(R)$ and $X = \text{Spec}(A)$ (possible as a finite morphism is affine). Then R and A are Noetherian rings and A is finite over R . Moreover $\mathcal{F} = \widetilde{M}$ for some finite A -module M . Note that $f_*\mathcal{F}$ corresponds to M viewed as an R -module. Let $\mathfrak{p} \subset R$ be the minimal prime corresponding to $\eta \in Y$. The coefficient of Z in $[f_*\mathcal{F}]_k$ is clearly $\text{length}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}})$. Let $\mathfrak{q}_i, i = 1, \dots, t$ be the primes of A lying over \mathfrak{p} . Then $A_{\mathfrak{p}} = \prod A_{\mathfrak{q}_i}$ since $A_{\mathfrak{p}}$ is an Artinian ring being finite over the dimension zero local Noetherian ring $R_{\mathfrak{p}}$. Clearly the coefficient of Z in $f_*[\mathcal{F}]_k$ is

$$\sum_{i=1, \dots, t} [\kappa(\mathfrak{q}_i) : \kappa(\mathfrak{p})] \text{length}_{A_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i})$$

Hence the desired equality follows from Algebra, Lemma 10.50.12. \square

41.13. Preparation for flat pullback

Recall that a morphism $f : X \rightarrow Y$ which is locally of finite type is said to have relative dimension r if every nonempty fibre is equidimensional of dimension r . See Morphisms, Definition 28.30.1.

Lemma 41.13.1. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume f is flat of relative dimension r . For any closed subset $Z \subset Y$ we have*

$$\dim_{\delta}(f^{-1}(Z)) = \dim_{\delta}(Z) + r.$$

If Z is irreducible and $Z' \subset f^{-1}(Z)$ is an irreducible component, then Z' dominates Z and $\dim_{\delta}(Z') = \dim_{\delta}(Z) + r$.

Proof. It suffices to prove the final statement. We may replace Y by the integral closed subscheme Z and X by the scheme theoretic inverse image $f^{-1}(Z) = Z \times_Y X$. Hence we may assume $Z = Y$ is integral and f is a flat morphism of relative dimension r . Since Y is locally Noetherian the morphism f which is locally of finite type, is actually locally of finite presentation. Hence Morphisms, Lemma 28.26.9 applies and we see that f is open. Let $\xi \in X$ be a generic point of an irreducible component of X . By the openness of f we see that $f(\xi)$ is the generic point η of $Z = Y$. Note that $\dim_{\xi}(X_{\eta}) = r$ by assumption that f has relative dimension r . On the other hand, since ξ is a generic point of X we see that $\mathcal{O}_{X, \xi} = \mathcal{O}_{X_{\eta}, \xi}$ has only one prime ideal and hence has dimension 0. Thus by Morphisms, Lemma 28.29.1 we conclude that the transcendence degree of $\kappa(\xi)$ over $\kappa(\eta)$ is r . In other words, $\delta(\xi) = \delta(\eta) + r$ as desired. \square

Here is the lemma that we will use to prove that the flat pullback of a locally finite collection of closed subschemes is locally finite.

Lemma 41.13.2. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume $\{Z_i\}_{i \in I}$ is a locally finite collection of closed subsets of Y . Then $\{f^{-1}(Z_i)\}_{i \in I}$ is a locally finite collection of closed subsets of X .*

Proof. Let $U \subset X$ be a quasi-compact open subset. Since the image $f(U) \subset Y$ is a quasi-compact subset there exists a quasi-compact open $V \subset Y$ such that $f(U) \subset V$. Note that

$$\{i \in I \mid f^{-1}(Z_i) \cap U \neq \emptyset\} \subset \{i \in I \mid Z_i \cap V \neq \emptyset\}.$$

Since the right hand side is finite by assumption we win. □

41.14. Flat pullback

In the following we use $f^{-1}(Z)$ to denote the *scheme theoretic inverse image* of a closed subscheme $Z \subset Y$ for a morphism of schemes $f : X \rightarrow Y$. We recall that the scheme theoretic inverse image is the fibre product

$$\begin{array}{ccc} f^{-1}(Z) & \longrightarrow & X \\ \downarrow & & \downarrow \\ Z & \longrightarrow & Y \end{array}$$

and it is also the closed subscheme of X cut out by the quasi-coherent sheaf of ideals $f^{-1}(\mathcal{I})\mathcal{O}_X$, if $\mathcal{I} \subset \mathcal{O}_Y$ is the quasi-coherent sheaf of ideals corresponding to Z in Y . (This is discussed in Schemes, Section 25.4 and Lemma 25.17.6 and Definition 25.17.7.)

Definition 41.14.1. Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a morphism. Assume f is flat of relative dimension r .

- (1) Let $Z \subset Y$ be an integral closed subscheme of δ -dimension k . We define $f^*[Z]$ to be the $(k+r)$ -cycle on X to the scheme theoretic inverse image

$$f^*[Z] = [f^{-1}(Z)]_{k+r}.$$

This makes sense since $\dim_\delta(f^{-1}(Z)) = k+r$ by Lemma 41.13.1.

- (2) Let $\alpha = \sum n_i[Z_i]$ be a k -cycle on Y . The *flat pullback of α by f* is the sum

$$f^*\alpha = \sum n_i f^*[Z_i]$$

where each $f^*[Z_i]$ is defined as above. The sum is locally finite by Lemma 41.13.2.

- (3) We denote $f^* : Z_k(Y) \rightarrow Z_{k+r}(X)$ the map of abelian groups so obtained.

An open immersion is flat. This is an important though trivial special case of a flat morphism. If $U \subset X$ is open then sometimes the pullback by $j : U \rightarrow X$ of a cycle is called the *restriction* of the cycle to U . Note that in this case the maps

$$j^* : Z_k(X) \longrightarrow Z_k(U)$$

are all *surjective*. The reason is that given any integral closed subscheme $Z' \subset U$, we can take the closure of Z' in X and think of it as a reduced closed subscheme of X (see Schemes, Lemma 25.12.4). And clearly $Z \cap U = Z'$, in other words $j^*[Z] = [Z']$ whence the surjectivity. In fact a little bit more is true.

Lemma 41.14.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $U \subset X$ be an open subscheme, and denote $i : Y = X \setminus U \rightarrow X$ as a reduced closed subscheme of X . For every $k \in \mathbf{Z}$ the sequence*

$$Z_k(Y) \xrightarrow{i_*} Z_k(X) \xrightarrow{j^*} Z_k(U) \longrightarrow 0$$

is an exact complex of abelian groups.

Proof. By the description above the basis elements $[Z]$ of the free abelian group $Z_k(X)$ map either to (distinct) basis elements $[Z \cap U]$ or to zero if $Z \subset Y$. Hence the lemma is clear. \square

Lemma 41.14.3. *Let (S, δ) be as in Situation 41.7.1. Let X, Y, Z be locally of finite type over S . Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be flat morphisms of relative dimensions r and s . Then $g \circ f$ is flat of relative dimension $r + s$ and*

$$f^* \circ g^* = (g \circ f)^*$$

as maps $Z_k(Z) \rightarrow Z_{k+r+s}(X)$.

Proof. The composition is flat of relative dimension $r + s$ by Morphisms, Lemma 28.30.3. Suppose that

- (1) $W \subset Z$ is a closed integral subscheme of δ -dimension k ,
- (2) $W' \subset Y$ is a closed integral subscheme of δ -dimension $k + s$ with $W' \subset g^{-1}(W)$, and
- (3) $W'' \subset Y$ is a closed integral subscheme of δ -dimension $k + s + r$ with $W'' \subset f^{-1}(W')$.

We have to show that the coefficient n of $[W'']$ in $(g \circ f)^*[W]$ agrees with the coefficient m of $[W'']$ in $f^*(g^*[W])$. That it suffices to check the lemma in these cases follows from Lemma 41.13.1. Let $\xi'' \in W''$, $\xi' \in W'$ and $\xi \in W$ be the generic points. Consider the local rings $A = \mathcal{O}_{Z, \xi}$, $B = \mathcal{O}_{Y, \xi'}$ and $C = \mathcal{O}_{X, \xi''}$. Then we have local flat ring maps $A \rightarrow B$, $B \rightarrow C$ and moreover

$$n = \text{length}_C(C/\mathfrak{m}_A C), \quad \text{and} \quad m = \text{length}_C(C/\mathfrak{m}_B C) \text{length}_B(B/\mathfrak{m}_A B)$$

Hence the equality follows from Algebra, Lemma 10.50.14. \square

Lemma 41.14.4. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r .*

- (1) *Let $Z \subset Y$ be a closed subscheme with $\dim_\delta(Z) \leq k$. Then we have $\dim_\delta(f^{-1}(Z)) \leq k + r$ and $[f^{-1}(Z)]_{k+r} = f^*[Z]_k$ in $Z_{k+r}(X)$.*
- (2) *Let \mathcal{F} be a coherent sheaf on Y with $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$. Then we have $\dim_\delta(\text{Supp}(f^*\mathcal{F})) \leq k + r$ and*

$$f^*[\mathcal{F}]_k = [f^*\mathcal{F}]_{k+r}$$

in $Z_{k+r}(X)$.

Proof. Part (1) follows from part (2) by Lemma 41.10.3 and the fact that $f^*\mathcal{O}_Z = \mathcal{O}_{f^{-1}(Z)}$.

Proof of (2). As X, Y are locally Noetherian we may apply Cohomology of Schemes, Lemma 29.9.1 to see that \mathcal{F} is of finite type, hence $f^*\mathcal{F}$ is of finite type (Modules, Lemma 17.9.2), hence $f^*\mathcal{F}$ is coherent (Cohomology of Schemes, Lemma 29.9.1 again). Thus the lemma makes sense. Let $W \subset Y$ be an integral closed subscheme of δ -dimension k , and let $W' \subset X$ be an integral closed subscheme of dimension

$k + r$ mapping into W under f . We have to show that the coefficient n of $[W]$ in $f^*[\mathcal{F}]_k$ agrees with the coefficient m of $[W]$ in $[f^*\mathcal{F}]_{k+r}$. Let $\xi \in W$ and $\xi' \in W'$ be the generic points. Let $A = \mathcal{O}_{Y,\xi}$, $B = \mathcal{O}_{X,\xi'}$ and set $M = \mathcal{F}_\xi$ as an A -module. (Note that M has finite length by our dimension assumptions, but we actually do not need to verify this. See Lemma 41.10.1.) We have $f^*\mathcal{F}_{\xi'} = B \otimes_A M$. Thus we see that

$$n = \text{length}_B(B \otimes_A M) \quad \text{and} \quad m = \text{length}_A(M)\text{length}_B(B/\mathfrak{m}_A B)$$

Thus the equality follows from Algebra, Lemma 10.50.13. □

41.15. Push and pull

In this section we verify that proper pushforward and flat pullback are compatible when this makes sense. By the work we did above this is a consequence of cohomology and base change.

Lemma 41.15.1. *Let (S, δ) be as in Situation 41.7.1. Let*

$$\begin{array}{ccc} X' & \xrightarrow{\quad} & X \\ f' \downarrow & & \downarrow f \\ Y' & \xrightarrow{\quad g \quad} & Y \end{array}$$

be a fibre product diagram of schemes locally of finite type over S . Assume $f : X \rightarrow Y$ proper and $g : Y' \rightarrow Y$ flat of relative dimension r . Then also f' is proper and g' is flat of relative dimension r . For any k -cycle α on X we have

$$g^* f_* \alpha = f'_*(g')^* \alpha$$

in $Z_{k+r}(Y')$.

Proof. The assertion that f' is proper follows from Morphisms, Lemma 28.42.5. The assertion that g' is flat of relative dimension r follows from Morphisms, Lemmas 28.30.2 and 28.26.7. It suffices to prove the equality of cycles when $\alpha = [W]$ for some integral closed subscheme $W \subset X$ of δ -dimension k . Note that in this case we have $\alpha = [\mathcal{O}_W]_k$, see Lemma 41.10.3. By Lemmas 41.12.3 and 41.14.4 it therefore suffices to show that $f'_*(g')^*\mathcal{O}_W$ is isomorphic to $g^*f_*\mathcal{O}_W$. This follows from cohomology and base change, see Cohomology of Schemes, Lemma 29.5.2. □

Lemma 41.15.2. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a finite locally free morphism of degree d (see Morphisms, Definition 28.46.1). Then f is both proper and flat of relative dimension 0, and*

$$f_* f^* \alpha = d\alpha$$

for every $\alpha \in Z_k(Y)$.

Proof. A finite locally free morphism is flat and finite by Morphisms, Lemma 28.46.2, and a finite morphism is proper by Morphisms, Lemma 28.44.10. We omit showing that a finite morphism has relative dimension 0. Thus the formula makes sense. To prove it, let $Z \subset Y$ be an integral closed subscheme of δ -dimension k . It suffices to prove the formula for $\alpha = [Z]$. Since the base change of a finite locally free morphism is finite locally free (Morphisms, Lemma 28.46.4) we see that $f_* f^* \mathcal{O}_Z$ is a finite locally free sheaf of rank d on Z . Hence

$$f_* f^* [Z] = f_* f^* [\mathcal{O}_Z]_k = [f_* f^* \mathcal{O}_Z]_k = d[Z]$$

where we have used Lemmas 41.14.4 and 41.12.3. \square

41.16. Preparation for principal divisors

Recall that if Z is an irreducible closed subset of a scheme X , then the codimension of Z in X is equal to the dimension of the local ring $\mathcal{O}_{X,\xi}$, where $\xi \in Z$ is the generic point. See Properties, Lemma 27.11.4.

Definition 41.16.1. Let X be a locally Noetherian scheme. Assume X is integral. Let $f \in R(X)^*$. For every integral closed subscheme $Z \subset X$ of codimension 1 we define the *order of vanishing of f along Z* as the integer

$$\text{ord}_Z(f) = \text{ord}_{\mathcal{O}_{X,\xi}}(f)$$

where the right hand side is the notion of Algebra, Definition 10.117.2 and ξ is the generic point of Z .

Of course it can happen that $\text{ord}_Z(f) < 0$. In this case we say that f has a *pole* along Z and that $-\text{ord}_Z(f) > 0$ is the *order of pole of f along Z* . Note that for $f, g \in R(X)^*$ we have

$$\text{ord}_Z(fg) = \text{ord}_Z(f) + \text{ord}_Z(g).$$

Lemma 41.16.2. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral. If $Z \subset X$ is an integral closed subscheme of codimension 1, then $\dim_\delta(Z) = \dim_\delta(X) - 1$.

Proof. This is more or less the defining property of a dimension function. \square

Lemma 41.16.3. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral. Let $f \in R(X)^*$. Then the set

$$\{Z \subset X \mid Z \text{ is integral, closed of codimension 1 and } \text{ord}_Z(f) \neq 0\}$$

is locally finite in X .

Proof. This is true simply because there exists a nonempty open subscheme $U \subset X$ such that f corresponds to a section of $\Gamma(U, \mathcal{O}_X^*)$, and hence the codimension 1 irreducibles which can occur in the set of the lemma are all irreducible components of $X \setminus U$. Hence Lemma 41.9.1 gives the desired result. \square

Lemma 41.16.4. Let $f : X \rightarrow Y$ be a morphism of schemes. Let $\xi \in Y$ be a point. Assume that

- (1) X, Y are integral,
- (2) X is locally Noetherian
- (3) f is proper, dominant and $R(X) \subset R(Y)$ is finite, and
- (4) $\dim(\mathcal{O}_{Y,\xi}) = 1$.

Then there exists an open neighbourhood $V \subset Y$ of ξ such that $f|_{f^{-1}(V)} : f^{-1}(V) \rightarrow V$ is finite.

Proof. This lemma is a special case of Varieties, Lemma 32.24.2. Here is a direct argument in this case. By Cohomology of Schemes, Lemma 29.19.2 it suffices to prove that $f^{-1}(\{\xi\})$ is finite. We replace Y by an affine open, say $Y = \text{Spec}(R)$. Note that R is Noetherian, as X is assumed locally Noetherian. Since f is proper it is quasi-compact. Hence we can find a finite affine open covering $X = U_1 \cup \dots \cup U_n$ with each $U_i = \text{Spec}(A_i)$. Note that $R \rightarrow A_i$ is a finite type injective

homomorphism of domains with $f.f.(R) \subset f.f.(A_i)$ finite. Thus the lemma follows from Algebra, Lemma 10.109.2. \square

41.17. Principal divisors

The following definition is the key to everything that follows.

Definition 41.17.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral with $\dim_\delta(X) = n$. Let $f \in R(X)^*$. The *principal divisor associated to f* is the $(n - 1)$ -cycle

$$\text{div}(f) = \text{div}_X(f) = \sum \text{ord}_Z(f)[Z]$$

where the sum is over integral closed subschemes of codimension 1 and $\text{ord}_Z(f)$ is as in Definition 41.16.1. This makes sense by Lemmas 41.16.2 and 41.16.3.

Lemma 41.17.2. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral with $\dim_\delta(X) = n$. Let $f, g \in R(X)^*$. Then

$$\text{div}(fg) = \text{div}(f) + \text{div}(g)$$

in $Z_{n-1}(X)$.

Proof. This is clear from the additivity of the ord functions. \square

An important role in the discussion of principal divisors is played by the “universal” principal divisor $[0] - [\infty]$ on \mathbf{P}_S^1 . To make this more precise, let us denote

$$D_0, D_\infty \subset \mathbf{P}_S^1 = \text{Proj}_S(\mathcal{O}_S[X_0, X_1])$$

the closed subscheme cut out by the section X_1 , resp. X_0 of $\mathcal{O}(1)$. These are effective Cartier divisors, see Divisors, Definition 30.9.1 and Lemma 30.9.20. The following lemma says that loosely speaking we have “ $\text{div}(X_1/X_0) = [D_0] - [D_1]$ ” and that this is the universal principal divisor.

Lemma 41.17.3. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let $f \in R(X)^*$. Let $U \subset X$ be a nonempty open such that f corresponds to a section $f \in \Gamma(U, \mathcal{O}_X^*)$. Let $Y \subset X \times_S \mathbf{P}_S^1$ be the closure of the graph of $f : U \rightarrow \mathbf{P}_S^1$. Then

- (1) the projection morphism $p : Y \rightarrow X$ is proper,
- (2) $p|_{p^{-1}(U)} : p^{-1}(U) \rightarrow U$ is an isomorphism,
- (3) the pullbacks $q^{-1}D_0$ and $q^{-1}D_\infty$ via the morphism $q : Y \rightarrow \mathbf{P}_S^1$ are effective Cartier divisors on Y ,
- (4) we have

$$\text{div}_Y(f) = [q^{-1}D_0]_{n-1} - [q^{-1}D_\infty]_{n-1}$$

- (5) we have

$$\text{div}_X(f) = p_* \text{div}_Y(f)$$

- (6) if we view $Y_0 = q^{-1}D_0$, and $Y_\infty = q^{-1}D_\infty$ as closed subschemes of X via the morphism p then we have

$$\text{div}_X(f) = [Y_0]_{n-1} - [Y_\infty]_{n-1}$$

Proof. Since X is integral, we see that U is integral. Hence Y is integral, and $(1, f)(U) \subset Y$ is an open dense subscheme. Also, note that the closed subscheme $Y \subset X \times_S \mathbf{P}_S^1$ does not depend on the choice of the open U , since after all it is the closure of the one point set $\{\eta'\} = \{(1, f)(\eta)\}$ where $\eta \in X$ is the generic point. Having said this let us prove the assertions of the lemma.

For (1) note that p is the composition of the closed immersion $Y \rightarrow X \times_S \mathbf{P}_S^1 = \mathbf{P}_X^1$ with the proper morphism $\mathbf{P}_X^1 \rightarrow X$. As a composition of proper morphisms is proper (Morphisms, Lemma 28.42.4) we conclude.

It is clear that $Y \cap U \times_S \mathbf{P}_S^1 = (1, f)(U)$. Thus (2) follows. It also follows that $\dim_\delta(Y) = n$.

Note that $q(\eta') = f(\eta)$ is not contained in D_0 or D_∞ since $f \in R(X)^*$. Hence $q^{-1}D_0$ and $q^{-1}D_\infty$ are effective Cartier divisors on Y by Divisors, Lemma 30.9.12. Thus we see (3). It also follows that $\dim_\delta(q^{-1}D_0) = n - 1$ and $\dim_\delta(q^{-1}D_\infty) = n - 1$.

Consider the effective Cartier divisor $q^{-1}D_0$. At every point $\xi \in q^{-1}D_0$ we have $f \in \mathcal{O}_{Y,\xi}$ and the local equation for $q^{-1}D_0$ is given by f . In particular, if $\delta(\xi) = n - 1$ so ξ is the generic point of a integral closed subscheme Z of δ -dimension $n - 1$, then we see that the coefficient of $[Z]$ in $\text{div}_Y(f)$ is

$$\text{ord}_Z(f) = \text{length}_{\mathcal{O}_{Y,\xi}}(\mathcal{O}_{Y,\xi}/f\mathcal{O}_{Y,\xi}) = \text{length}_{\mathcal{O}_{Y,\xi}}(\mathcal{O}_{q^{-1}D_0,\xi})$$

which is the coefficient of $[Z]$ in $[q^{-1}D_0]_{n-1}$. A similar argument using the rational function $1/f$ shows that $-[q^{-1}D_\infty]$ agrees with the terms with negative coefficients in the expression for $\text{div}_Y(f)$. Hence (4) follows.

Note that $D_0 \rightarrow S$ is an isomorphism. Hence we see that $X \times_S D_0 \rightarrow X$ is an isomorphism as well. Clearly we have $q^{-1}D_0 = Y \cap X \times_S D_0$ (scheme theoretic intersection) inside $X \times_S \mathbf{P}_S^1$. Hence it is really the case that $Y_0 \rightarrow X$ is a closed immersion. By the same token we see that

$$p_*\mathcal{O}_{q^{-1}D_0} = \mathcal{O}_{Y_0}$$

and hence by Lemma 41.12.3 we have $p_*[q^{-1}D_0]_{n-1} = [Y_0]_{n-1}$. Of course the same is true for D_∞ and Y_∞ . Hence to finish the proof of the lemma it suffices to prove the last assertion.

Let $Z \subset X$ be an integral closed subscheme of δ -dimension $n - 1$. We want to show that the coefficient of $[Z]$ in $\text{div}(f)$ is the same as the coefficient of $[Z]$ in $[Y_0]_{n-1} - [Y_\infty]_{n-1}$. We may apply Lemma 41.16.4 to the morphism $p : Y \rightarrow X$ and the generic point $\xi \in Z$. Hence we may replace X by an affine open neighbourhood of ξ and assume that $p : Y \rightarrow X$ is finite. Write $X = \text{Spec}(R)$ and $Y = \text{Spec}(A)$ with p induced by a finite homomorphism $R \rightarrow A$ of Noetherian domains which induces an isomorphism $f.f.(R) \cong f.f.(A)$ of fraction fields. Now we have $f \in f.f.(R)$ and a prime $\mathfrak{p} \subset R$ with $\dim(R_\mathfrak{p}) = 1$. The coefficient of $[Z]$ in $\text{div}_X(f)$ is $\text{ord}_{R_\mathfrak{p}}(f)$. The coefficient of $[Z]$ in $p_*\text{div}_Y(f)$ is

$$\sum_{\mathfrak{q} \text{ lying over } \mathfrak{p}} [\kappa(\mathfrak{q}) : \kappa(\mathfrak{p})] \text{ord}_{A_\mathfrak{q}}(f)$$

The desired equality therefore follows from Algebra, Lemma 10.117.8. □

This lemma will be superseded by the more general Lemma 41.20.1.

Lemma 41.17.4. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Assume X, Y are integral and $n = \dim_\delta(Y)$. Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r . Let $g \in R(Y)^*$. Then*

$$f^*(\operatorname{div}_Y(g)) = \operatorname{div}_X(g)$$

in $Z_{n+r-1}(X)$.

Proof. Note that since f is flat it is dominant so that f induces an embedding $R(Y) \subset R(X)$, and hence we may think of g as an element of $R(X)^*$. Let $Z \subset X$ be an integral closed subscheme of δ -dimension $n + r - 1$. Let $\xi \in Z$ be its generic point. If $\dim_\delta(f(Z)) > n - 1$, then we see that the coefficient of $[Z]$ in the left and right hand side of the equation is zero. Hence we may assume that $Z' = \overline{f(Z)}$ is an integral closed subscheme of Y of δ -dimension $n - 1$. Let $\xi' = f(\xi)$. It is the generic point of Z' . Set $A = \mathcal{O}_{Y, \xi'}$, $B = \mathcal{O}_{X, \xi}$. The ring map $A \rightarrow B$ is a flat local homomorphism of Noetherian local domains of dimension 1. We have $g \in f.f.(A)$. What we have to show is that

$$\operatorname{ord}_A(g)\operatorname{length}_B(B/\mathfrak{m}_A B) = \operatorname{ord}_B(g).$$

This follows from Algebra, Lemma 10.50.13 (details omitted). □

41.18. Two fun results on principal divisors

The first lemma implies that the pushforward of a principal divisor along a generically finite morphism is a principal divisor.

Lemma 41.18.1. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Assume X, Y are integral and $n = \dim_\delta(X) = \dim_\delta(Y)$. Let $p : X \rightarrow Y$ be a dominant proper morphism. Let $f \in R(X)^*$. Set*

$$g = Nm_{R(X)/R(Y)}(f).$$

Then we have $p_*\operatorname{div}(f) = \operatorname{div}(g)$.

Proof. Let $Z \subset Y$ be an integral closed subscheme of δ -dimension $n - 1$. We want to show that the coefficient of $[Z]$ in $p_*\operatorname{div}(f)$ and $\operatorname{div}(g)$ are equal. We may apply Lemma 41.16.4 to the morphism $p : X \rightarrow X$ and the generic point $\xi \in Z$. Hence we may replace X by an affine open neighbourhood of ξ and assume that $p : Y \rightarrow X$ is finite. Write $X = \operatorname{Spec}(R)$ and $Y = \operatorname{Spec}(A)$ with p induced by a finite homomorphism $R \rightarrow A$ of Noetherian domains which induces an finite field extension $f.f.(R) \subset f.f.(A)$ of fraction fields. Now we have $f \in f.f.(A)$, $g = Nm(f) \in f.f.(R)$, and a prime $\mathfrak{p} \subset R$ with $\dim(R_{\mathfrak{p}}) = 1$. The coefficient of $[Z]$ in $\operatorname{div}_Y(g)$ is $\operatorname{ord}_{R_{\mathfrak{p}}}(g)$. The coefficient of $[Z]$ in $p_*\operatorname{div}_X(f)$ is

$$\sum_{\mathfrak{q} \text{ lying over } \mathfrak{p}} [\kappa(\mathfrak{q}) : \kappa(\mathfrak{p})]\operatorname{ord}_{A_{\mathfrak{q}}}(f)$$

The desired equality therefore follows from Algebra, Lemma 10.117.8. □

The following lemma says that the degree of a principal divisor on a proper curve is zero.

Lemma 41.18.2. *Let K be any field. Let X be a 1-dimensional integral scheme endowed with a proper morphism $c : X \rightarrow \operatorname{Spec}(K)$. Let $f \in K(X)^*$ be an invertible rational function. Then*

$$\sum_{x \in X \text{ closed}} [\kappa(x) : K]\operatorname{ord}_{\mathcal{O}_{X,x}}(f) = 0$$

where ord is as in Algebra, Definition 10.117.2. In other words, $c_* \text{div}(f) = 0$.

Proof. Consider the diagram

$$\begin{array}{ccc} Y & \xrightarrow{p} & X \\ q \downarrow & & \downarrow c \\ \mathbf{P}_K^1 & \xrightarrow{c'} & \text{Spec}(K) \end{array}$$

that we constructed in Lemma 41.17.3 starting with X and the rational function f over $S = \text{Spec}(K)$. We will use all the results of this lemma without further mention. We have to show that $c_* \text{div}_X(f) = c_* p_* \text{div}_Y(f) = 0$. This is the same as proving that $c'_* q_* \text{div}_Y(f) = 0$. If $q(Y)$ is a closed point of \mathbf{P}_K^1 then we see that $\text{div}_X(f) = 0$ and the lemma holds. Thus we may assume that q is dominant. Since $\text{div}_Y(f) = [q^{-1}D_0]_0 - [q^{-1}D_\infty]_0$ we see (by definition of flat pullback) that $\text{div}_Y(f) = q^*([D_0]_0 - [D_\infty]_0)$. Suppose we can show that $q : Y \rightarrow \mathbf{P}_K^1$ is finite locally free of degree d (see Morphisms, Definition 28.46.1). Then by Lemma 41.15.2 we get $q_* \text{div}_Y(f) = d([D_0]_0 - [D_\infty]_0)$. Since clearly $c'_*[D_0]_0 = c'_*[D_\infty]_0$ we win.

It remains to show that q is finite locally free. (It will automatically have some given degree as \mathbf{P}_K^1 is connected.) Since $\dim(\mathbf{P}_K^1) = 1$ we see that q is finite for example by Lemma 41.16.4. All local rings of \mathbf{P}_K^1 at closed points are regular local rings of dimension 1 (in other words discrete valuation rings), since they are localizations of $K[T]$ (see Algebra, Lemma 10.110.1). Hence for $y \in Y$ closed the local ring $\mathcal{O}_{Y,y}$ will be flat over $\mathcal{O}_{\mathbf{P}_K^1, q(y)}$ as soon as it is torsion free. This is obviously the case as $\mathcal{O}_{Y,y}$ is a domain and q is dominant. Thus q is flat. Hence q is finite locally free by Morphisms, Lemma 28.46.2. \square

41.19. Rational equivalence

In this section we define *rational equivalence* on k -cycles. We will allow locally finite sums of images of principal divisors (under closed immersions). This leads to some pretty strange phenomena, see Example 41.19.3. However, if we do not allow these then we do not know how to prove that capping with chern classes of line bundles factors through rational equivalence.

Definition 41.19.1. Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Let $k \in \mathbf{Z}$.

- (1) Given any locally finite collection $\{W_j \subset X\}$ of integral closed subschemes with $\dim_\delta(W_j) = k + 1$, and any $f_j \in R(W_j)^*$ we may consider

$$\sum (i_j)_* \text{div}(f_j) \in Z_k(X)$$

where $i_j : W_j \rightarrow X$ is the inclusion morphism. This makes sense as the morphism $\coprod i_j : \coprod W_j \rightarrow X$ is proper.

- (2) We say that $\alpha \in Z_k(X)$ is *rationally equivalent to zero* if α is a cycle of the form displayed above.
- (3) We say $\alpha, \beta \in Z_k(X)$ are *rationally equivalent* and we write $\alpha \sim_{rat} \beta$ if $\alpha - \beta$ is rationally equivalent to zero.
- (4) We define

$$A_k(X) = Z_k(X) / \sim_{rat}$$

to be the *Chow group of k -cycles on X* . This is sometimes called the *Chow group of k -cycles module rational equivalence on X* .

There are many other interesting (adequate) equivalence relations. Rational equivalence is the coarsest one of them all. A very simple but important lemma is the following.

Lemma 41.19.2. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Let $U \subset X$ be an open subscheme, and denote $i : Y = X \setminus U \rightarrow X$ as a reduced closed subscheme of X . Let $k \in \mathbf{Z}$. Suppose $\alpha, \beta \in Z_k(X)$. If $\alpha|_U \sim_{\text{rat}} \beta|_U$ then there exist a cycle $\gamma \in Z_k(Y)$ such that*

$$\alpha \sim_{\text{rat}} \beta + i_*\gamma.$$

In other words, the sequence

$$A_k(Y) \xrightarrow{i_*} A_k(X) \xrightarrow{j_*} A_k(U) \longrightarrow 0$$

is an exact complex of abelian groups.

Proof. Let $\{W_j\}_{j \in J}$ be a locally finite collection of integral closed subschemes of δ -dimension $k + 1$, and let $f_j \in R(W_j)^*$ be elements such that $(\alpha - \beta)|_U = \sum (i_j)_* \text{div}(f_j)$ as in the definition. Set $W'_j \subset X$ equal to the closure of W_j . Suppose that $V \subset X$ is a quasi-compact open. Then also $V \cap U$ is quasi-compact open in U as V is Noetherian. Hence the set $\{j \in J \mid W_j \cap V \neq \emptyset\} = \{j \in J \mid W'_j \cap V \neq \emptyset\}$ is finite since $\{W_j\}$ is locally finite. In other words we see that $\{W'_j\}$ is also locally finite. Since $R(W_j) = R(W'_j)$ we see that

$$\alpha - \beta - \sum (i'_j)_* \text{div}(f_j)$$

is a cycle supported on Y and the lemma follows (see Lemma 41.14.2). □

Example 41.19.3. Here is a “strange” example. Suppose that S is the spectrum of a field k with δ as in Example 41.7.2. Suppose that $X = C_1 \cup C_2 \cup \dots$ is an infinite union of curves $C_j \cong \mathbf{P}_k^1$ glued together in the following way: The point $\infty \in C_j$ is glued transversally to the point $0 \in C_{j+1}$ for $j = 1, 2, 3, \dots$. Take the point $0 \in C_1$. This gives a zero cycle $[0] \in Z_0(X)$. The “strangeness” in this situation is that actually $[0] \sim_{\text{rat}} 0$! Namely we can choose the rational function $f_j \in R(C_j)$ to be the function which has a simple zero at 0 and a simple pole at ∞ and no other zeros or poles. Then we see that the sum $\sum (i_j)_* \text{div}(f_j)$ is exactly the 0-cycle $[0]$. In fact it turns out that $A_0(X) = 0$ in this example. If you find this too bizarre, then you can just make sure your spaces are always quasi-compact (so X does not even exist for you).

Remark 41.19.4. Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Suppose we have infinite collections $\alpha_i, \beta_i \in Z_k(X)$, $i \in I$ of k -cycles on X . Suppose that the supports of α_i and β_i form locally finite collections of closed subsets of X so that $\sum \alpha_i$ and $\sum \beta_i$ are defined as cycles. Moreover, assume that $\alpha_i \sim_{\text{rat}} \beta_i$ for each i . Then it is not clear that $\sum \alpha_i \sim_{\text{rat}} \sum \beta_i$. Namely, the problem is that the rational equivalences may be given by locally finite families $\{W_{i,j}, f_{i,j} \in R(W_{i,j})^*\}_{j \in J_i}$ but the union $\{W_{i,j}\}_{i \in I, j \in J_i}$ may not be locally finite.

In many cases in practice, one has a locally finite family of closed subsets $\{T_i\}_{i \in I}$ such that α_i, β_i are supported on T_i and such that $\alpha_i = \beta_i$ in $A_k(T_i)$, in other words,

the families $\{W_{i,j}, f_{i,j} \in R(W_{i,j})^*\}_{j \in J_i}$ consist of subschemes $W_{i,j} \subset T_i$. In this case it is true that $\sum \alpha_i \sim_{rat} \sum \beta_i$ on X , simply because the family $\{W_{i,j}\}_{i \in I, j \in J_i}$ is automatically locally finite in this case.

41.20. Properties of rational equivalence

Lemma 41.20.1. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be schemes locally of finite type over S . Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r . Let $\alpha \sim_{rat} \beta$ be rationally equivalent k -cycles on Y . Then $f^*\alpha \sim_{rat} f^*\beta$ as $(k + r)$ -cycles on X .*

Proof. What do we have to show? Well, suppose we are given a collection

$$i_j : W_j \longrightarrow Y$$

of closed immersions, with each W_j integral of δ -dimension $k + 1$ and rational functions $f_j \in R(W_j)^*$. Moreover, assume that the collection $\{i_j(W_j)\}_{j \in J}$ is locally finite on Y . Then we have to show that

$$f^*(\sum i_{j,*} \text{div}(f_j))$$

is rationally equivalent to zero on X .

Consider the fibre products

$$i'_j : W'_j = W_j \times_Y X \longrightarrow X.$$

For each j , consider the collection $\{W'_{j,l}\}_{l \in L_j}$ of irreducible components $W'_{j,l} \subset W'_j$ having δ -dimension $k + 1$. We may write

$$[W'_j]_{k+1} = \sum_{l \in L_j} n_{j,l} [W'_{j,l}]_{k+1}$$

for some $n_{j,l} > 0$. By Lemma 41.13.1 we see that $W'_{j,l} \rightarrow W_j$ is dominant and hence we can let $f_{j,l} \in R(W'_{j,l})^*$ denote the image of f_j under the map of fields $R(W_j) \rightarrow R(W'_{j,l})$. We claim that

- (1) the collection $\{W'_{j,l}\}_{j \in J, l \in L_j}$ is locally finite on X , and
- (2) with obvious notation $f^*(\sum i_{j,*} \text{div}(f_j)) = \sum i'_{j,l,*} \text{div}(f_{j,l}^{n_{j,l}})$.

Clearly this claim implies the lemma.

To show (1), note that $\{W'_j\}$ is a locally finite collection of closed subschemes of X by Lemma 41.13.2. Hence if $U \subset X$ is quasi-compact, then U meets only finitely many W'_j . By Lemma 41.9.1 the collection of irreducible components of each W_j is locally finite as well. Hence we see only finitely many $W'_{j,l}$ meet U as desired.

Let $Z \subset X$ be an integral closed subscheme of δ -dimension $k + r$. We have to show that the coefficient n of $[Z]$ in $f^*(\sum i_{j,*} \text{div}(f_j))$ is equal to the coefficient m of $[Z]$ in $\sum i'_{j,l,*} \text{div}(f_{j,l}^{n_{j,l}})$. Let Z' be the closure of $f(Z)$ which is an integral closed subscheme of Y . By Lemma 41.13.1 we have $\dim_\delta(Z') \geq k$. If $\dim_\delta(Z') > k$, then the coefficients n and m are both zero, since the generic point of Z will not be contained in any W'_j or $W'_{j,l}$. Hence we may assume that $\dim_\delta(Z') = k$.

We are going to translate the equality of n and m into algebra. Namely, let $\xi' \in Z'$ and $\xi \in Z$ be the generic points. Set $A = \mathcal{O}_{Y, \xi'}$ and $B = \mathcal{O}_{X, \xi}$. Note that A, B are Noetherian, $A \rightarrow B$ is flat, local, and that $\mathfrak{m}_A B$ is an ideal of definition of the

local ring B . There are finitely many j such that W_j passes through ξ' , and these correspond to prime ideals

$$\mathfrak{p}_1, \dots, \mathfrak{p}_T \subset A$$

with the property that $\dim(A/\mathfrak{p}_t) = 1$ for each $t = 1, \dots, T$. The rational functions f_j correspond to elements $f_t \in \kappa(\mathfrak{p}_t)^*$. Say \mathfrak{p}_t corresponds to W_j . By construction, the closed subschemes $W'_{j,l}$ which meet ξ correspond 1 – 1 with minimal primes

$$\mathfrak{p}_t B \subset \mathfrak{q}_{t,1}, \dots, \mathfrak{q}_{t,S_t} \subset B$$

over $\mathfrak{p}_t B$. The integers $n_{j,l}$ correspond to the integers

$$n_{t,s} = \text{length}_{B_{\mathfrak{q}_{t,s}}}((B/\mathfrak{p}_t B)_{B_{\mathfrak{q}_{t,s}}})$$

The rational functions $f_{j,l}$ correspond to the images $f_{t,s} \in \kappa(\mathfrak{q}_{t,s})^*$ of the elements $f_t \in \kappa(\mathfrak{p}_t)^*$. Putting everything together we see that

$$n = \sum \text{ord}_{A/\mathfrak{p}_t}(f_t) \text{length}_B(B/\mathfrak{m}_A B)$$

and that

$$m = \sum \text{ord}_{B/\mathfrak{q}_{t,s}}(f_{t,s}) \text{length}_{B_{\mathfrak{q}_{t,s}}}((B/\mathfrak{p}_t B)_{B_{\mathfrak{q}_{t,s}}})$$

Note that it suffices to prove the equality for each $t \in \{1, \dots, T\}$ separately. Writing $f_t = x/y$ for some nonzero $\bar{x}, \bar{y} \in A/\mathfrak{p}_t$ coming from $x, y \in A$ we see that it suffices to prove

$$\text{length}_{A/\mathfrak{p}_t}(A/(\mathfrak{p}_t, x)) \text{length}_B(B/\mathfrak{m}_A B) = \text{length}_B(B/(x, \mathfrak{p}_t)B)$$

(equality uses Algebra, Lemma 10.50.13) equals

$$\sum_{s=1, \dots, S_t} \text{ord}_{B/\mathfrak{q}_{t,s}}(B/(x, \mathfrak{q}_{t,s})) \text{length}_{B_{\mathfrak{q}_{t,s}}}((B/\mathfrak{p}_t B)_{B_{\mathfrak{q}_{t,s}}})$$

and similarly for y . Note that as $x \notin \mathfrak{p}_t$ we see that x is a nonzerodivisor on A/\mathfrak{p}_t . As $A \rightarrow B$ is flat it follows that x is a nonzerodivisor on the module $M = B/\mathfrak{p}_t B$. Hence the equality above follows from Lemma 41.5.6. \square

Lemma 41.20.2. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be schemes locally of finite type over S . Let $p : X \rightarrow Y$ be a proper morphism. Suppose $\alpha, \beta \in Z_k(X)$ are rationally equivalent. Then $p_*\alpha$ is rationally equivalent to $p_*\beta$.*

Proof. What do we have to show? Well, suppose we are given a collection

$$i_j : W_j \rightarrow X$$

of closed immersions, with each W_j integral of δ -dimension $k + 1$ and rational functions $f_j \in R(W_j)^*$. Moreover, assume that the collection $\{i_j(W_j)\}_{j \in J}$ is locally finite on X . Then we have to show that

$$p_* \left(\sum i_{j,*} \text{div}(f_j) \right)$$

is rationally equivalent to zero on X .

Note that the sum is equal to

$$\sum p_* i_{j,*} \text{div}(f_j).$$

Let $W'_j \subset Y$ be the integral closed subscheme which is the image of $p \circ i_j$. The collection $\{W'_j\}$ is locally finite in Y by Lemma 41.11.2. Hence it suffices to show, for a given j , that either $p_* i_{j,*} \text{div}(f_j) = 0$ or that it is equal to $i'_{j,*} \text{div}(g_j)$ for some $g_j \in R(W'_j)^*$.

The arguments above therefore reduce us to the case of a since integral closed subscheme $W \subset X$ of δ -dimension $k + 1$. Let $f \in R(W)^*$. Let $W' = p(W)$ as above. We get a commutative diagram of morphisms

$$\begin{array}{ccc} W & \longrightarrow & X \\ p' \downarrow & & \downarrow p \\ W' & \xrightarrow{i'} & Y \end{array}$$

Note that $p_*i_*\text{div}(f) = i'_*(p')_*\text{div}(f)$ by Lemma 41.12.2. As explained above we have to show that $(p')_*\text{div}(f)$ is the divisor of a rational function on W' or zero. There are three cases to distinguish.

The case $\dim_\delta(W') < k$. In this case automatically $(p')_*\text{div}(f) = 0$ and there is nothing to prove.

The case $\dim_\delta(W') = k$. Let us show that $(p')_*\text{div}(f) = 0$ in this case. Let $\eta \in W'$ be the generic point. Note that $c : W_\eta \rightarrow \text{Spec}(K)$ is a proper integral curve over $K = \kappa(\eta)$ whose function field $K(W_\eta)$ is identified with $R(W)$. Here is a diagram

$$\begin{array}{ccc} W_\eta & \longrightarrow & W \\ c \downarrow & & \downarrow p' \\ \text{Spec}(K) & \longrightarrow & W' \end{array}$$

Let us denote $f_\eta \in K(W_\eta)^*$ the rational function corresponding to $f \in R(W)^*$. Moreover, the closed points ξ of W_η correspond 1 – 1 to the closed integral subschemes $Z = Z_\xi \subset W$ of δ -dimension k with $p'(Z) = W'$. Note that the multiplicity of Z_ξ in $\text{div}(f)$ is equal to $\text{ord}_{\mathcal{O}_{W_\eta, \xi}}(f_\eta)$ simply because the local rings $\mathcal{O}_{W_\eta, \xi}$ and $\mathcal{O}_{W, \xi}$ are identified (as subrings of their fraction fields). Hence we see that the multiplicity of $[W']$ in $(p')_*\text{div}(f)$ is equal to the multiplicity of $[\text{Spec}(K)]$ in $c_*\text{div}(f_\eta)$. By Lemma 41.18.2 this is zero.

The case $\dim_\delta(W') = k + 1$. In this case Lemma 41.18.1 applies, and we see that indeed $p'_*\text{div}(f) = \text{div}(g)$ for some $g \in R(W')^*$ as desired. \square

41.21. Different characterizations of rational equivalence

Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Given any closed subscheme $Z \subset X \times_S \mathbf{P}_S^1 = X \times \mathbf{P}^1$ we let Z_0 , resp. Z_∞ be the scheme theoretic closed subscheme $Z_0 = \text{pr}_2^{-1}(D_0)$, resp. $Z_\infty = \text{pr}_2^{-1}(D_\infty)$. Here D_0, D_∞ are as defined just above Lemma 41.17.3.

Lemma 41.21.1. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Let $W \subset X \times_S \mathbf{P}_S^1$ be an integral closed subscheme of δ -dimension $k + 1$. Assume $W \neq W_0$, and $W \neq W_\infty$. Then*

- (1) W_0, W_∞ are effective Cartier divisors of W ,
- (2) W_0, W_∞ can be viewed as closed subschemes of X and

$$[W_0]_k \sim_{\text{rat}} [W_\infty]_k,$$

- (3) for any locally finite family of integral closed subschemes $W_i \subset X \times_S \mathbf{P}_S^1$ of δ -dimension $k + 1$ with $W_i \neq (W_i)_0$ and $W_i \neq (W_i)_\infty$ we have $\sum([(W_i)_0]_k - [(W_i)_\infty]_k) \sim_{\text{rat}} 0$ on X , and

- (4) for any $\alpha \in Z_k(X)$ with $\alpha \sim_{rat} 0$ there exists a locally finite family of integral closed subschemes $W_i \subset X \times_S \mathbf{P}_S^1$ as above such that $\alpha = \sum([W_i]_0)_k - [W_i]_\infty)_k$.

Proof. Part (1) follows from Divisors, Lemma 30.9.12 since the generic point of W is not mapped into D_0 or D_∞ under the projection $X \times_S \mathbf{P}_S^1 \rightarrow \mathbf{P}_S^1$ by assumption.

Since $X \times_S D_0 \rightarrow X$ is an isomorphism we see that W_0 is isomorphic to a closed subscheme of X . Similarly for W_∞ . Consider the morphism $p : W \rightarrow X$. It is proper and on W we have $[W_0]_k \sim_{rat} [W_\infty]_k$. Hence part (2) follows from Lemma 41.20.2 as clearly $p_*[W_0]_k = [W_0]_k$ and similarly for W_∞ .

The only content of statement (3) is, given parts (1) and (2), that the collection $\{(W_i)_0, (W_i)_\infty\}$ is a locally finite collection of closed subschemes of X . This is clear.

Suppose that $\alpha \sim_{rat} 0$. By definition this means there exist integral closed subschemes $V_i \subset X$ of δ -dimension $k + 1$ and rational functions $f_i \in R(V_i)^*$ such that the family $\{V_i\}_{i \in I}$ is locally finite in X and such that $\alpha = \sum(V_i \rightarrow X)_* \text{div}(f_i)$. Let

$$W_i \subset V_i \times_S \mathbf{P}_S^1 \subset X \times_S \mathbf{P}_S^1$$

be the closure of the graph of the rational map f_i as in Lemma 41.17.3. Then we have that $(V_i \rightarrow X)_* \text{div}(f_i)$ is equal to $[(W_i)_0]_k - [(W_i)_\infty]_k$ by that same lemma. Hence the result is clear. \square

Lemma 41.21.2. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Let Z be a closed subscheme of $X \times \mathbf{P}^1$. Assume $\dim_\delta(Z) \leq k + 1$, $\dim_\delta(Z_0) \leq k$, $\dim_\delta(Z_\infty) \leq k$ and assume any embedded point ξ (Divisors, Definition 30.4.1) of Z has $\delta(\xi) < k$. Then*

$$[Z_0]_k \sim_{rat} [Z_\infty]_k$$

as k -cycles on X .

Proof. Let $\{W_i\}_{i \in I}$ be the collection of irreducible components of Z which have δ -dimension $k + 1$. Write

$$[Z]_{k+1} = \sum n_i [W_i]$$

with $n_i > 0$ as per definition. Note that $\{W_i\}$ is a locally finite collection of closed subsets of $X \times_S \mathbf{P}_S^1$ by Lemma 41.9.1. We claim that

$$[Z_0]_k = \sum n_i [(W_i)_0]_k$$

and similarly for $[Z_\infty]_k$. If we prove this then the lemma follows from Lemma 41.21.1.

Let $Z' \subset X$ be an integral closed subscheme of δ -dimension k . To prove the equality above it suffices to show that the coefficient n of $[Z']$ in $[Z_0]_k$ is the same as the coefficient m of $[Z']$ in $\sum n_i [(W_i)_0]_k$. Let $\xi' \in Z'$ be the generic point. Set $\xi = (\xi', 0) \in X \times_S \mathbf{P}_S^1$. Consider the local ring $A = \mathcal{O}_{X \times_S \mathbf{P}_S^1, \xi}$. Let $I \subset A$ be the ideal cutting out Z , in other words so that $A/I = \mathcal{O}_{Z, \xi}$. Let $t \in A$ be the element cutting out $X \times_S D_0$ (i.e., the coordinate of \mathbf{P}^1 at zero pulled back). By our choice of $\xi' \in Z'$ we have $\delta(\xi) = k$ and hence $\dim(A/I) = 1$. Since ξ is not an embedded point by definition we see that A/I is Cohen-Macaulay. Since $\dim_\delta(Z_0) = k$ we see that $\dim(A/(t, I)) = 0$ which implies that t is a nonzerodivisor on A/I . Finally, the irreducible closed subschemes W_i passing through ξ correspond

to the minimal primes $I \subset \mathfrak{q}_i$ over I . The multiplicities n_i correspond to the lengths $\text{length}_{A_{\mathfrak{q}_i}}(A/I)_{\mathfrak{q}_i}$. Hence we see that

$$n = \text{length}_A(A/(t, I))$$

and

$$m = \sum \text{length}_A(A/(t, \mathfrak{q}_i)) \text{length}_{A_{\mathfrak{q}_i}}(A/I)_{\mathfrak{q}_i}$$

Thus the result follows from Lemma 41.5.6. □

Lemma 41.21.3. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Let \mathcal{F} be a coherent sheaf on $X \times \mathbf{P}^1$. Let $i_0, i_\infty : X \rightarrow X \times \mathbf{P}^1$ be the closed immersion such that $i_t(x) = (x, t)$. Denote $\mathcal{F}_0 = i_0^* \mathcal{F}$ and $\mathcal{F}_\infty = i_\infty^* \mathcal{F}$. Assume*

- (1) $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k + 1$,
- (2) $\dim_\delta(\text{Supp}(\mathcal{F}_0)) \leq k$, $\dim_\delta(\text{Supp}(\mathcal{F}_\infty)) \leq k$, and
- (3) any nonmaximal associated point (insert future reference here) $\xi \in \text{Supp}(\mathcal{F})$ of \mathcal{F} has $\delta(\xi) < k$.

Then

$$[\mathcal{F}_0]_k \sim_{\text{rat}} [\mathcal{F}_\infty]_k$$

as k -cycles on X .

Proof. Let $\{W_i\}_{i \in I}$ be the collection of irreducible components of $\text{Supp}(\mathcal{F})$ which have δ -dimension $k + 1$. Write

$$[\mathcal{F}]_{k+1} = \sum n_i [W_i]$$

with $n_i > 0$ as per definition. Note that $\{W_i\}$ is a locally finite collection of closed subsets of $X \times_S \mathbf{P}_S^1$ by Lemma 41.10.1. We claim that

$$[\mathcal{F}_0]_k = \sum n_i [(W_i)_0]_k$$

and similarly for $[\mathcal{F}_\infty]_k$. If we prove this then the lemma follows from Lemma 41.21.1.

Let $Z' \subset X$ be an integral closed subscheme of δ -dimension k . To prove the equality above it suffices to show that the coefficient n of $[Z']$ in $[\mathcal{F}_0]_k$ is the same as the coefficient m of $[Z']$ in $\sum n_i [(W_i)_0]_k$. Let $\xi' \in Z'$ be the generic point. Set $\xi = (\xi', 0) \in X \times_S \mathbf{P}_S^1$. Consider the local ring $A = \mathcal{O}_{X \times_S \mathbf{P}_S^1, \xi}$. Let $M = \mathcal{F}_\xi$ as an A -module. Let $t \in A$ be the element cutting out $X \times_S D_0$ (i.e., the coordinate of \mathbf{P}^1 at zero pulled back). By our choice of $\xi' \in Z'$ we have $\delta(\xi) = k$ and hence $\dim(M) = 1$. Since ξ is not an associated point of \mathcal{F} by definition we see that M is Cohen-Macaulay module. Since $\dim_\delta(\text{Supp}(\mathcal{F}_0)) = k$ we see that $\dim(M/tM) = 0$ which implies that t is a nonzerodivisor on M . Finally, the irreducible closed subschemes W_i passing through ξ correspond to the minimal primes \mathfrak{q}_i of $\text{Ass}(M)$. The multiplicities n_i correspond to the lengths $\text{length}_{A_{\mathfrak{q}_i}} M_{\mathfrak{q}_i}$. Hence we see that

$$n = \text{length}_A(M/tM)$$

and

$$m = \sum \text{length}_A(A/(t, \mathfrak{q}_i)A) \text{length}_{A_{\mathfrak{q}_i}} M_{\mathfrak{q}_i}$$

Thus the result follows from Lemma 41.5.6. □

41.22. Rational equivalence and K-groups

In this section we compare the cycle groups $Z_k(X)$ and the Chow groups $A_k(X)$ with certain K_0 -groups of abelian categories of coherent sheaves on X . We avoid having to talk about $K_1(\mathcal{A})$ for an abelian category \mathcal{A} by dint of Homology, Lemma 12.10.3. In particular, the motivation for the precise form of Lemma 41.22.4 is that lemma.

Let us introduce the following notation. Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . We denote $Coh(X) = Coh(\mathcal{O}_X)$ the category of coherent sheaves on X . It is an abelian category, see Cohomology of Schemes, Lemma 29.9.2. For any $k \in \mathbf{Z}$ we let $Coh_{\leq k}(X)$ be the full subcategory of $Coh(X)$ consisting of those coherent sheaves \mathcal{F} having $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k$.

Lemma 41.22.1. *Let us introduce the following notation. Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . The categories $Coh_{\leq k}(X)$ are Serre subcategories of the abelian category $Coh(X)$.*

Proof. Omitted. The definition of a Serre subcategory is Homology, Definition 12.9.1. □

Lemma 41.22.2. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . There are maps*

$$Z_k(X) \longrightarrow K_0(Coh_{\leq k}(X)/Coh_{\leq k-1}(X)) \longrightarrow Z_k(X)$$

whose composition is the identity. The first is the map

$$\sum n_Z[Z] \mapsto \left[\bigoplus_{n_Z > 0} \mathcal{O}_Z^{\oplus n_Z} \right] - \left[\bigoplus_{n_Z < 0} \mathcal{O}_Z^{\oplus -n_Z} \right]$$

and the second comes from the map $\mathcal{F} \mapsto [\mathcal{F}]_k$. If X is quasi-compact, then both maps are isomorphisms.

Proof. Note that the direct sum $\bigoplus_{n_Z > 0} \mathcal{O}_Z^{\oplus n_Z}$ is indeed a coherent sheaf on X since the family $\{Z \mid n_Z > 0\}$ is locally finite on X . The map $\mathcal{F} \rightarrow [\mathcal{F}]_k$ is additive on $Coh_{\leq k}(X)$, see Lemma 41.10.4. And $[\mathcal{F}]_k = 0$ if $\mathcal{F} \in Coh_{\leq k-1}(X)$. This implies we have the left map as shown in the lemma. It is clear that their composition is the identity.

In case X is quasi-compact we will show that the right arrow is injective. Suppose that $q \in K_0(Coh_{\leq k}(X)/Coh_{\leq k+1}(X))$ maps to zero in $Z_k(X)$. By Homology, Lemma 12.10.3 we can find a $\tilde{q} \in K_0(Coh_{\leq k}(X))$ mapping to q . Write $\tilde{q} = [\mathcal{F}] - [\mathcal{G}]$ for some $\mathcal{F}, \mathcal{G} \in K_0(Coh_{\leq k}(X))$. Since X is quasi-compact we may apply Cohomology of Schemes, Lemma 29.12.3. This shows that there exist integral closed subschemes $Z_j, T_i \subset X$ and (nonzero) ideal sheaves $\mathcal{I}_j \subset \mathcal{O}_{Z_j}, \mathcal{I}_i \subset \mathcal{O}_{T_i}$ such that \mathcal{F} , resp. \mathcal{G} have filtrations whose successive quotients are the sheaves \mathcal{I}_j , resp. \mathcal{I}_i . In particular we see that $\dim_\delta(Z_j), \dim_\delta(T_i) \leq k$. In other words we have

$$[\mathcal{F}] = \sum_j [\mathcal{I}_j], \quad [\mathcal{G}] = \sum_i [\mathcal{I}_i],$$

in $K_0(Coh_{\leq k}(X))$. Our assumption is that $\sum_j [\mathcal{I}_j]_k - \sum_i [\mathcal{I}_i]_k = 0$. It is clear that we may throw out the indices j , resp. i such that $\dim_\delta(Z_j) < k$, resp. $\dim_\delta(T_i) < k$, since the corresponding sheaves are in $Coh_{k-1}(X)$ and also do not contribute to the cycle. Moreover, the exact sequences $0 \rightarrow \mathcal{I}_j \rightarrow \mathcal{O}_{Z_j} \rightarrow \mathcal{O}_{Z_j}/\mathcal{I}_j \rightarrow 0$ and

$0 \rightarrow \mathcal{I}_i \rightarrow \mathcal{O}_{T_i} \rightarrow \mathcal{O}_{Z_i}/\mathcal{I}_i \rightarrow 0$ show similarly that we may replace \mathcal{I}_j , resp. \mathcal{I}_i by \mathcal{O}_{Z_j} , resp. \mathcal{O}_{T_i} . OK, and finally, at this point it is clear that our assumption

$$\sum_j [\mathcal{O}_{Z_j}]_k - \sum_i [\mathcal{O}_{T_i}]_k = 0$$

implies that in $K_0(\text{Coh}_k(X))$ we have also $\sum_j [\mathcal{O}_{Z_j}] - \sum_i [\mathcal{O}_{T_i}] = 0$ as desired. \square

Remark 41.22.3. It seems likely that the arrows of Lemma 41.22.2 are not isomorphisms if X is not quasi-compact. For example, suppose X is an infinite disjoint union $X = \coprod_{n \in \mathbf{N}} \mathbf{P}_k^1$ over a field k . Let \mathcal{F} , resp. \mathcal{G} be the coherent sheaf on X whose restriction to the n th summand is equal to the skyscraper sheaf at 0 associated to $\mathcal{O}_{\mathbf{P}_k^1,0}/\mathfrak{m}_0^n$, resp. $\kappa(0)^{\oplus n}$. The cycle associated to \mathcal{F} is equal to the cycle associated to \mathcal{G} , namely both are equal to $\sum n[0_n]$ where $0_n \in X$ denotes 0 on the n th component of X . But there seems to be no way to show that $[\mathcal{F}] = [\mathcal{G}]$ in $K_0(\text{Coh}(X))$ since any proof we can envision uses infinitely many relations.

Lemma 41.22.4. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Let \mathcal{F} be a coherent sheaf on X . Let*

$$\dots \longrightarrow \mathcal{F} \xrightarrow{\varphi} \mathcal{F} \xrightarrow{\psi} \mathcal{F} \xrightarrow{\varphi} \mathcal{F} \longrightarrow \dots$$

be a complex as in Homology, Equation (12.10.2.1). Assume that

- (1) $\dim_\delta(\text{Supp}(\mathcal{F})) \leq k + 1$.
- (2) $\dim_\delta(\text{Supp}(H^i(\mathcal{F}, \varphi, \psi))) \leq k$ for $i = 0, 1$.

Then we have

$$[H^0(\mathcal{F}, \varphi, \psi)]_k \sim_{\text{rat}} [H^1(\mathcal{F}, \varphi, \psi)]_k$$

as k -cycles on X .

Proof. Let $\{W_j\}_{j \in J}$ be the collection of irreducible components of $\text{Supp}(\mathcal{F})$ which have δ -dimension $k + 1$. Note that $\{W_j\}$ is a locally finite collection of closed subsets of X by Lemma 41.10.1. For every j , let $\xi_j \in W_j$ be the generic point. Set

$$f_j = \det_{\kappa(\xi_j)}(\mathcal{F}_{\xi_j}, \varphi_{\xi_j}, \psi_{\xi_j}) \in R(W_j)^*.$$

See Definition 41.3.4 for notation. We claim that

$$-[H^0(\mathcal{F}, \varphi, \psi)]_k + [H^1(\mathcal{F}, \varphi, \psi)]_k = \sum (W_j \rightarrow X)_* \text{div}(f_j)$$

If we prove this then the lemma follows.

Let $Z \subset X$ be an integral closed subscheme of δ -dimension k . To prove the equality above it suffices to show that the coefficient n of $[Z]$ in $[H^0(\mathcal{F}, \varphi, \psi)]_k - [H^1(\mathcal{F}, \varphi, \psi)]_k$ is the same as the coefficient m of $[Z]$ in $\sum (W_j \rightarrow X)_* \text{div}(f_j)$. Let $\xi \in Z$ be the generic point. Consider the local ring $A = \mathcal{O}_{X,\xi}$. Let $M = \mathcal{F}_\xi$ as an A -module. Denote $\varphi, \psi : M \rightarrow M$ the action of φ, ψ on the stalk. By our choice of $\xi \in Z$ we have $\delta(\xi) = k$ and hence $\dim(M) = 1$. Finally, the integral closed subschemes W_j passing through ξ correspond to the minimal primes \mathfrak{q}_i of $\text{Supp}(M)$. In each case the element $f_j \in R(W_j)^*$ corresponds to the element $\det_{\kappa(\mathfrak{q}_i)}(M_{\mathfrak{q}_i}, \varphi, \psi)$ in $\kappa(\mathfrak{q}_i)^*$. Hence we see that

$$n = -e_A(M, \varphi, \psi)$$

and

$$m = \sum \text{ord}_{A/\mathfrak{q}_i}(\det_{\kappa(\mathfrak{q}_i)}(M_{\mathfrak{q}_i}, \varphi, \psi))$$

Thus the result follows from Proposition 41.5.3. \square

Lemma 41.22.5. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Denote $B_k(X)$ the image of the map*

$$K_0(\text{Coh}_{\leq k}(X)/\text{Coh}_{\leq k-1}(X)) \longrightarrow K_0(\text{Coh}_{\leq k+1}(X)/\text{Coh}_{\leq k-1}(X)).$$

There is a commutative diagram

$$\begin{CD} K_0\left(\frac{\text{Coh}_{\leq k}(X)}{\text{Coh}_{\leq k-1}(X)}\right) @>>> B_k(X) @<<< K_0\left(\frac{\text{Coh}_{\leq k+1}(X)}{\text{Coh}_{\leq k-1}(X)}\right) \\ @VVV @VVV @. \\ Z_k(X) @>>> A_k(X) @. \end{CD}$$

where the left vertical arrow is the one from Lemma 41.22.2. If X is quasi-compact then both vertical arrows are isomorphisms.

Proof. Suppose we have an element $[A] - [B]$ of $K_0(\text{Coh}_{\leq k}(X)/\text{Coh}_{\leq k-1}(X))$ which maps to zero in $B_k(X)$, i.e., in $K_0(\text{Coh}_{\leq k+1}(X)/\text{Coh}_{\leq k-1}(X))$. Suppose $[A] = [\mathcal{A}]$ and $[B] = [\mathcal{B}]$ for some coherent sheaves \mathcal{A}, \mathcal{B} on X supported in δ -dimension $\leq k$. The assumption that $[A] - [B]$ maps to zero in the group $K_0(\text{Coh}_{\leq k+1}(X)/\text{Coh}_{\leq k-1}(X))$ means that there exists coherent sheaves $\mathcal{A}', \mathcal{B}'$ on X supported in δ -dimension $\leq k - 1$ such that $[\mathcal{A} \oplus \mathcal{A}'] - [\mathcal{B} \oplus \mathcal{B}']$ is zero in $K_0(\text{Coh}_{\leq k+1}(X))$ (use part (1) of Homology, Lemma 12.10.3). By part (2) of Homology, Lemma 12.10.3 this means there exists a $(2, 1)$ -periodic complex $(\mathcal{F}, \varphi, \psi)$ in the category $\text{Coh}_{\leq k+1}(X)$ such that $\mathcal{A} \oplus \mathcal{A}' = H^0(\mathcal{F}, \varphi, \psi)$ and $\mathcal{B} \oplus \mathcal{B}' = H^1(\mathcal{F}, \varphi, \psi)$. By Lemma 41.22.4 this implies that

$$[\mathcal{A} \oplus \mathcal{A}']_k \sim_{rat} [\mathcal{B} \oplus \mathcal{B}']_k$$

This proves that $[A] - [B]$ maps to zero via the composition

$$K_0(\text{Coh}_{\leq k}(X)/\text{Coh}_{\leq k-1}(X)) \longrightarrow Z_k(X) \longrightarrow A_k(X).$$

In other words this proves the commutative diagram exists.

Next, assume that X is quasi-compact. By Lemma 41.22.2 the left vertical arrow is bijective. Hence it suffices to show any $\alpha \in Z_k(X)$ which is rationally equivalent to zero maps to zero in $B_k(X)$ via the inverse of the left vertical arrow composed with the horizontal arrow. By Lemma 41.21.1 we see that $\alpha = \sum([\mathcal{O}_{(W_i)_0}]_k - [\mathcal{O}_{(W_i)_\infty}]_k)$ for some closed integral subschemes $W_i \subset X \times_S \mathbf{P}^1_S$ of δ -dimension $k + 1$. Moreover the family $\{W_i\}$ is finite because X is quasi-compact. Note that the ideal sheaves $\mathcal{I}_i, \mathcal{J}_i \subset \mathcal{O}_{W_i}$ of the effective Cartier divisors $(W_i)_0, (W_i)_\infty$ are isomorphic (as \mathcal{O}_{W_i} -modules). This is true because the ideal sheaves of D_0 and D_∞ on \mathbf{P}^1 are isomorphic and $\mathcal{I}_i, \mathcal{J}_i$ are the pullbacks of these. (Some details omitted.) Hence we have short exact sequences

$$0 \rightarrow \mathcal{I}_i \rightarrow \mathcal{O}_{W_i} \rightarrow \mathcal{O}_{(W_i)_0} \rightarrow 0, \quad 0 \rightarrow \mathcal{J}_i \rightarrow \mathcal{O}_{W_i} \rightarrow \mathcal{O}_{(W_i)_\infty} \rightarrow 0$$

of coherent \mathcal{O}_{W_i} -modules. Also, since $[\mathcal{O}_{(W_i)_0}]_k = [p_*\mathcal{O}_{(W_i)_0}]_k$ in $Z_k(X)$ we see that the inverse of the left vertical arrow maps $[\mathcal{O}_{(W_i)_0}]_k$ to the element $[p_*\mathcal{O}_{(W_i)_0}]$ in $K_0(\text{Coh}_{\leq k}(X)/\text{Coh}_{\leq k-1}(X))$. Thus we have

$$\begin{aligned} \alpha &= \sum([\mathcal{O}_{(W_i)_0}]_k - [\mathcal{O}_{(W_i)_\infty}]_k) \\ &\mapsto \sum([p_*\mathcal{O}_{(W_i)_0}] - [p_*\mathcal{O}_{(W_i)_\infty}]) \\ &= \sum([p_*\mathcal{O}_{W_i}] - [p_*\mathcal{I}_i] - [p_*\mathcal{O}_{W_i}] + [p_*\mathcal{J}_i]) \end{aligned}$$

in $K_0(\text{Coh}_{\leq k+1}(X)/\text{Coh}_{\leq k-1}(X))$. By what was said above this is zero, and we win. \square

Remark 41.22.6. Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Assume X is quasi-compact. The result of Lemma 41.22.5 in particular gives a map

$$A_k(X) \longrightarrow K_0(\text{Coh}(X)/\text{Coh}_{\leq k-1}(X)).$$

We have not been able to find a statement or conjecture in the literature as to whether this map should be injective or not. If X is connected nonsingular, then, using the isomorphism $K_0(X) = K^0(X)$ (see insert future reference here) and chern classes (see below), one can show that the map is an isomorphism up to $(p-1)!$ -torsion where $p = \dim_\delta(X) - k$.

41.23. Preparation for the divisor associated to an invertible sheaf

For the following remarks, see Divisors, Section 30.15. Let X be a scheme. Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let $\xi \in X$ be a point. If $s_\xi, s'_\xi \in \mathcal{L}_\xi$ generate \mathcal{L}_ξ as $\mathcal{O}_{X,\xi}$ -module, then there exists a unit $u \in \mathcal{O}_{X,\xi}^*$ such that $s_\xi = us'_\xi$. The stalk of the sheaf of meromorphic sections $\mathcal{K}_X(\mathcal{L})$ of \mathcal{L} at x is equal to $\mathcal{K}_{X,x} \otimes_{\mathcal{O}_{X,x}} \mathcal{L}_x$. Thus the image of any meromorphic section s of \mathcal{L} in the stalk at x can be written as $s = fs_\xi$ with $f \in \mathcal{K}_{X,x}$. Below we will abbreviate this by saying $f = s/s_\xi$. Also, if X is integral we have $\mathcal{K}_{X,x} = R(X)$ is equal to the function field of X , so $s/s_\xi \in R(X)$. If s is a regular meromorphic section (see Divisors, Definition 30.15.11), then actually $f \in R(X)^*$. (On an integral scheme a regular meromorphic section is the same thing as a nonzero meromorphic section.) Hence the following definition makes sense.

Definition 41.23.1. Let X be a locally Noetherian scheme. Assume X is integral. Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let $s \in \Gamma(X, \mathcal{K}_X(\mathcal{L}))$ be a regular meromorphic section of \mathcal{L} . For every integral closed subscheme $Z \subset X$ of codimension 1 we define the *order of vanishing of s along Z* as the integer

$$\text{ord}_{Z,\mathcal{L}}(s) = \text{ord}_{\mathcal{O}_{X,\xi}}(s/s_\xi)$$

where the right hand side is the notion of Algebra, Definition 10.117.2, $\xi \in Z$ is the generic point, and $s_\xi \in \mathcal{L}_\xi$ is a generator.

Lemma 41.23.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral. Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let $s \in \mathcal{K}_X(\mathcal{L})$ be a regular (i.e., nonzero) meromorphic section of \mathcal{L} . Then the set*

$$\{Z \subset X \mid Z \text{ is irreducible, closed of codimension 1 and } \text{ord}_{Z,\mathcal{L}}(s) \neq 0\}$$

is locally finite in X .

Proof. This is true simply because there exists a nonempty open subscheme $U \subset X$ such that s corresponds to a section of $\Gamma(U, \mathcal{L})$ which generates \mathcal{L} over U . Hence the codimension 1 irreducibles which can occur in the set of the lemma are all irreducible components of $X \setminus U$. Hence Lemma 41.9.1 gives the desired result. \square

Lemma 41.23.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let $s, s' \in \mathcal{K}_X(\mathcal{L})$ be nonzero meromorphic sections of \mathcal{L} . Then $f = s/s'$ is an element of $R(X)^*$ and we have*

$$\sum \text{ord}_{Z, \mathcal{L}}(s)[Z] = \sum \text{ord}_{Z, \mathcal{L}}(s')[Z] + \text{div}(f)$$

(where the sums are over integral closed subschemes $Z \subset X$ of δ -dimension $n - 1$) as elements of $Z_{n-1}(X)$.

Proof. This is clear from the definitions. Note that Lemma 41.23.2 guarantees that the sums are indeed elements of $Z_{n-1}(X)$. \square

41.24. The divisor associated to an invertible sheaf

The material above allows us to define the divisor associated to an invertible sheaf.

Definition 41.24.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let \mathcal{L} be an invertible \mathcal{O}_X -module.

- (1) For any nonzero meromorphic section s of \mathcal{L} we define the *Weil divisor associated to s* as

$$\text{div}_{\mathcal{L}}(s) := \sum \text{ord}_{Z, \mathcal{L}}(s)[Z] \in Z_{n-1}(X)$$

where the sum is over integral closed subschemes $Z \subset X$ of δ -dimension $n - 1$.

- (2) We define *Weil divisor associated to \mathcal{L}*

$$c_1(\mathcal{L}) \cap [X] = \text{class of } \text{div}_{\mathcal{L}}(s) \in A_{n-1}(X)$$

where s is any nonzero meromorphic section of \mathcal{L} over X . This is well defined by Lemma 41.23.3.

There are some cases where it is easy to compute the Weil divisor associated to an invertible sheaf.

Lemma 41.24.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let $s \in \Gamma(X, \mathcal{L})$ be a nonzero global section. Then*

$$\text{div}_{\mathcal{L}}(s) = [Z(s)]_{n-1}$$

in $Z_{n-1}(X)$ and

$$c_1(\mathcal{L}) \cap [X] = [Z(s)]_{n-1}$$

in $A_{n-1}(X)$.

Proof. Let $Z \subset X$ be an integral closed subscheme of δ -dimension $n - 1$. Let $\xi \in Z$ be its generic point. Choose a generator $s_\xi \in \mathcal{L}_\xi$. Write $s = fs_\xi$ for some $f \in \mathcal{O}_{X, \xi}$. By definition of $Z(s)$, see Divisors, Definition 30.9.18 we see that $Z(s)$ is cut out by a quasi-coherent sheaf of ideals $\mathcal{I} \subset \mathcal{O}_X$ such that $\mathcal{I}_\xi = (f)$. Hence $\text{length}_{\mathcal{O}_{X, x}}(\mathcal{O}_{Z(s), \xi}) = \text{length}_{\mathcal{O}_{X, x}}(\mathcal{O}_{X, \xi}/(f)) = \text{ord}_{\mathcal{O}_{X, x}}(f)$ as desired. \square

Lemma 41.24.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let \mathcal{L}, \mathcal{N} be invertible \mathcal{O}_X -modules. Then*

- (1) Let s , resp. t be a nonzero meromorphic section of \mathcal{L} , resp. \mathcal{N} . Then st is a nonzero meromorphic section of $\mathcal{L} \otimes \mathcal{N}$, and

$$\operatorname{div}_{\mathcal{L} \otimes \mathcal{N}}(st) = \operatorname{div}_{\mathcal{L}}(s) + \operatorname{div}_{\mathcal{N}}(t)$$

in $Z_{n-1}(X)$.

- (2) We have

$$c_1(\mathcal{L}) \cap [X] + c_1(\mathcal{N}) \cap [X] = c_1(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{N}) \cap [X]$$

in $A_{n-1}(X)$.

Proof. Let s , resp. t be a nonzero meromorphic section of \mathcal{L} , resp. \mathcal{N} . Then st is a nonzero meromorphic section of $\mathcal{L} \otimes \mathcal{N}$. Let $Z \subset X$ be an integral closed subscheme of δ -dimension $n - 1$. Let $\xi \in Z$ be its generic point. Choose generators $s_\xi \in \mathcal{L}_\xi$, and $t_\xi \in \mathcal{N}_\xi$. Then $s_\xi t_\xi$ is a generator for $(\mathcal{L} \otimes \mathcal{N})_\xi$. So $st/(s_\xi t_\xi) = (s/s_\xi)(t/t_\xi)$. Hence we see that

$$\operatorname{div}_{\mathcal{L} \otimes \mathcal{N}, Z}(st) = \operatorname{div}_{\mathcal{L}, Z}(s) + \operatorname{div}_{\mathcal{N}, Z}(t)$$

by the additivity of the ord_Z function. □

The following lemma will be superseded by the more general Lemma 41.25.4.

Lemma 41.24.4. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Assume X, Y are integral and $n = \dim_\delta(Y)$. Let \mathcal{L} be an invertible \mathcal{O}_Y -module. Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r . Let \mathcal{L} be an invertible sheaf on Y . Then*

$$f^*(c_1(\mathcal{L}) \cap [Y]) = c_1(f^*\mathcal{L}) \cap [X]$$

in $A_{n+r-1}(X)$.

Proof. Let s be a nonzero meromorphic section of \mathcal{L} . We will show that actually $f^*\operatorname{div}_{\mathcal{L}}(s) = \operatorname{div}_{f^*\mathcal{L}}(f^*s)$ and hence the lemma holds. To see this let $\xi \in Y$ be a point and let $s_\xi \in \mathcal{L}_\xi$ be a generator. Write $s = gs_\xi$ with $g \in R(X)^*$. Then there is an open neighbourhood $V \subset Y$ of ξ such that $s_\xi \in \mathcal{L}(V)$ and such that s_ξ generates $\mathcal{L}|_V$. Hence we see that

$$\operatorname{div}_{\mathcal{L}}(s)|_V = \operatorname{div}(g)|_V.$$

In exactly the same way, since f^*s_ξ generates \mathcal{L} over $f^{-1}(V)$ and since $f^*s = gf^*s_\xi$ we also have

$$\operatorname{div}_{\mathcal{L}}(f^*s)|_{f^{-1}(V)} = \operatorname{div}(g)|_{f^{-1}(V)}.$$

Thus the desired equality of cycles over $f^{-1}(V)$ follows from the corresponding result for pullbacks of principal divisors, see Lemma 41.17.4. □

41.25. Intersecting with Cartier divisors

Definition 41.25.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L} be an invertible \mathcal{O}_X -module. We define, for every integer k , an operation

$$c_1(\mathcal{L}) \cap - : Z_{k+1}(X) \rightarrow A_k(X)$$

called *intersection with the first chern class of \mathcal{L}* .

- (1) Given an integral closed subscheme $i : W \rightarrow X$ with $\dim_\delta(W) = k + 1$ we define

$$c_1(\mathcal{L}) \cap [W] = i_*(c_1(i^*\mathcal{L}) \cap [W])$$

where the right hand side is defined in Definition 41.24.1.

(2) For a general $(k + 1)$ -cycle $\alpha = \sum n_i[W_i]$ we set

$$c_1(\mathcal{L}) \cap \alpha = \sum n_i c_1(\mathcal{L}) \cap [W_i]$$

Write each $c_1(\mathcal{L}) \cap W_i = \sum_j n_{i,j}[Z_{i,j}]$ with $\{Z_{i,j}\}_j$ a locally finite sum of integral closed subschemes of W_i . Since $\{W_i\}$ is a locally finite collection of integral closed subschemes on X , it follows easily that $\{Z_{i,j}\}_{i,j}$ is a locally finite collection of closed subschemes of X . Hence $c_1(\mathcal{L}) \cap \alpha = \sum n_i n_{i,j}[Z_{i,j}]$ is a cycle. Another, more convenient, way to think about this is to observe that the morphism $\coprod W_i \rightarrow X$ is proper. Hence $c_1(\mathcal{L}) \cap \alpha$ can be viewed as the pushforward of a class in $A_k(\coprod W_i) = \coprod A_k(W_i)$. This also explains why the result is well defined up to rational equivalence on X .

The main goal for the next few sections is to show that intersecting with $c_1(\mathcal{L})$ factors through rational equivalence, and is commutative. This is not a triviality.

Lemma 41.25.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L}, \mathcal{N} be invertible sheaves on X . Then*

$$c_1(\mathcal{L}) \cap \alpha + c_1(\mathcal{N}) \cap \alpha = c_1(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{N}) \cap \alpha$$

in $A_k(X)$ for every $\alpha \in Z_{k-1}(X)$. Moreover, $c_1(\mathcal{O}_X) \cap \alpha = 0$ for all α .

Proof. The additivity follows directly from Lemma 41.24.3 and the definitions. To see that $c_1(\mathcal{O}_X) \cap \alpha = 0$ consider the section $1 \in \Gamma(X, \mathcal{O}_X)$. This restricts to an everywhere nonzero section on any integral closed subscheme $W \subset X$. Hence $c_1(\mathcal{O}_X) \cap [W] = 0$ as desired. \square

The following lemma is a useful result in order to compute the intersection product of the c_1 of an invertible sheaf and the cycle associated to a closed subscheme. Recall that $Z(s) \subset X$ denotes the zero scheme of a global section s of an invertible sheaf on a scheme X , see Divisors, Definition 30.9.18.

Lemma 41.25.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let $Z \subset X$ be a closed subscheme. Assume $\dim_\delta(Z) \leq k + 1$. Let $s \in \Gamma(Z, \mathcal{L}|_Z)$. Assume*

- (1) $\dim_\delta(Z(s)) \leq k$, and
- (2) for every generic point ξ of an irreducible component of $Z(s)$ of dimension k the multiplication by s induces an injection $\mathcal{O}_{Z,\xi} \rightarrow (\mathcal{L}|_Z)_\xi$.

This holds for example if s is a regular section of $\mathcal{L}|_Z$. Then

$$[Z(s)]_k = c_1(\mathcal{L}) \cap [Z]_{k+1}$$

in $A_k(X)$.

Proof. Write

$$[Z]_{k+1} = \sum n_i[W_i]$$

where $W_i \subset Z$ are the irreducible components of Z of δ -dimension $k + 1$ and $n_i > 0$. By assumption the restriction $s_i = s|_{W_i} \in \Gamma(W_i, \mathcal{L}|_{W_i})$ is not zero, and hence is a regular section. By Lemma 41.24.2 we see that $[Z(s_i)]_k$ represents $c_1(\mathcal{L}|_{W_i})$. Hence by definition

$$c_1(\mathcal{L}) \cap [Z]_{k+1} = \sum n_i [Z(s_i)]_k$$

In fact, the proof below will show that we have

$$(41.25.3.1) \quad [Z(s)]_k = \sum n_i [Z(s_i)]_k$$

as k -cycles on X .

Let $Z' \subset X$ be an integral closed subscheme of δ -dimension k . Let $\xi' \in Z'$ be its generic point. We want to compare the coefficient n of $[Z']$ in the expression $\sum n_i [Z(s_i)]_k$ with the coefficient m of $[Z']$ in the expression $[Z(s)]_k$. Choose a generator $s_{\xi'} \in \mathcal{L}_{\xi'}$. Let $\mathcal{I} \subset \mathcal{O}_X$ be the ideal sheaf of Z . Write $A = \mathcal{O}_{X, \xi'}$, $L = \mathcal{L}_{\xi'}$ and $I = \mathcal{I}_{\xi'}$. Then $L = As_{\xi'}$ and $L/IL = (A/I)s_{\xi'} = (\mathcal{L}|_Z)_{\xi'}$. Write $s = fs_{\xi'}$ for some (unique) $f \in A/I$. Hypothesis (2) means that $f : A/I \rightarrow A/I$ is injective. Since $\dim_{\delta}(Z) \leq k + 1$ and $\dim_{\delta}(Z') = k$ we have $\dim(A/I) = 0$ or 1 . We have

$$m = \text{length}_A(A/(f, I))$$

which is finite in either case.

If $\dim(A/I) = 0$, then $f : A/I \rightarrow A/I$ being injective implies that $f \in (A/I)^*$. Hence in this case m is zero. Moreover, the condition $\dim(A/I) = 0$ means that ξ' does not lie on any irreducible component of δ -dimension $k + 1$, i.e., $n = 0$ as well.

Now, let $\dim(A/I) = 1$. Since A is a Noetherian local ring there are finitely many minimal primes $\mathfrak{q}_1, \dots, \mathfrak{q}_t \supset I$ over I . These correspond 1-1 with W_i passing through ξ' . Moreover $n_i = \text{length}_{A_{\mathfrak{q}_i}}((A/I)_{\mathfrak{q}_i})$. Also, the multiplicity of $[Z']$ in $[Z(s_i)]_k$ is $\text{length}_A(A/(f, \mathfrak{q}_i))$. Hence the equation to prove in this case is

$$\text{length}_A(A/(f, I)) = \sum \text{length}_{A_{\mathfrak{q}_i}}((A/I)_{\mathfrak{q}_i}) \text{length}_A(A/(f, \mathfrak{q}_i))$$

which follows from Lemma 41.5.6. □

Lemma 41.25.4. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r . Let \mathcal{L} be an invertible sheaf on Y . Let α be a k -cycle on Y . Then*

$$f^*(c_1(\mathcal{L}) \cap \alpha) = c_1(f^*\mathcal{L}) \cap f^*\alpha$$

in $A_{k+r-1}(X)$.

Proof. Write $\alpha = \sum n_i [W_i]$. We claim it suffices to show that $f^*(c_1(\mathcal{L}) \cap [W_i]) = c_1(f^*\mathcal{L}) \cap f^*[W_i]$ for each i . Proof of this claim is omitted. (Remarks: it is clear in the quasi-compact case. Something similar happened in the proof of Lemma 41.20.1, and one can copy the method used there here. Another possibility is to check the cycles and rational equivalences used for all W_i combined at each step form a locally finite collection).

Let $W \subset Y$ be an integral closed subscheme of δ -dimension k . We have to show that $f^*(c_1(\mathcal{L}) \cap [W]) = c_1(f^*\mathcal{L}) \cap f^*[W]$. Consider the following fibre product diagram

$$\begin{array}{ccc} W' = W \times_Y X & \longrightarrow & X \\ \downarrow & & \downarrow \\ W & \longrightarrow & Y \end{array}$$

and let $W'_i \subset W'$ be the irreducible components of δ -dimension $k + r$. Write $[W']_{k+r} = \sum n_i [W'_i]$ with $n_i > 0$ as per definition. So $f^*[W] = \sum n_i [W'_i]$. Choose a nonzero meromorphic section s of $\mathcal{L}|_W$. Since each $W'_i \rightarrow W$ is dominant we see that $s_i = s|_{W'_i}$ is a nonzero meromorphic section for each i . We claim that we have the following equality of cycles

$$\sum n_i \text{div}_{\mathcal{L}|_{W'_i}}(s_i) = f^* \text{div}_{\mathcal{L}|_W}(s)$$

in $Z_{k+r-1}(X)$.

Having formulated the problem as an equality of cycles we may work locally on Y . Hence we may assume Y and also W affine, and $s = p/q$ for some nonzero sections $p \in \Gamma(W, \mathcal{L})$ and $q \in \Gamma(W, \mathcal{O})$. If we can show both

$$\sum n_i \operatorname{div}_{\mathcal{L}|_{W_i}}(p_i) = f^* \operatorname{div}_{\mathcal{L}|_W}(p), \quad \text{and} \quad \sum n_i \operatorname{div}_{\mathcal{O}|_{W_i}}(q_i) = f^* \operatorname{div}_{\mathcal{O}|_W}(q)$$

(with obvious notations) then we win by the additivity, see Lemma 41.24.3. Thus we may assume that $s \in \Gamma(W, \mathcal{L}|_W)$. In this case we may apply the equality (41.25.3.1) obtained in the proof of Lemma 41.25.3 to see that

$$\sum n_i \operatorname{div}_{\mathcal{L}|_{W_i}}(s_i) = [Z(s')]_{k+r-1}$$

where $s' \in f^* \mathcal{L}|_{W'}$ denotes the pullback of s to W' . On the other hand we have

$$f^* \operatorname{div}_{\mathcal{L}|_W}(s) = f^* [Z(s)]_{k-1} = [f^{-1}(Z(s))]_{k+r-1},$$

by Lemmas 41.24.2 and 41.14.4. Since $Z(s') = f^{-1}(Z(s))$ we win. □

Lemma 41.25.5. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a proper morphism. Let \mathcal{L} be an invertible sheaf on Y . Let s be a nonzero meromorphic section s of \mathcal{L} on Y . Assume X, Y integral, f dominant, and $\dim_\delta(X) = \dim_\delta(Y)$. Then*

$$f_*(\operatorname{div}_{f^* \mathcal{L}}(f^* s)) = [R(X) : R(Y)] \operatorname{div}_{\mathcal{L}}(s).$$

In particular

$$f_*(c_1(f^* \mathcal{L}) \cap [X]) = c_1(\mathcal{L}) \cap f_*[Y].$$

Proof. The last equation follows from the first since $f_*[X] = [R(X) : R(Y)][Y]$ by definition. It turns out that we can re-use Lemma 41.18.1 to prove this. Namely, since we are trying to prove an equality of cycles, we may work locally on Y . Hence we may assume that $\mathcal{L} = \mathcal{O}_Y$. In this case s corresponds to a rational function $g \in R(Y)$, and we are simply trying to prove

$$f_*(\operatorname{div}_X(g)) = [R(X) : R(Y)] \operatorname{div}_Y(g).$$

Comparing with the result of the aforementioned Lemma 41.18.1 we see this true since $\operatorname{Nm}_{R(X)/R(Y)}(g) = g^{[R(X):R(Y)]}$ as $g \in R(Y)^*$. □

Lemma 41.25.6. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $p : X \rightarrow Y$ be a proper morphism. Let $\alpha \in Z_{k+1}(X)$. Let \mathcal{L} be an invertible sheaf on Y . Then*

$$p_*(c_1(p^* \mathcal{L}) \cap \alpha) = c_1(\mathcal{L}) \cap p_* \alpha$$

in $A_k(Y)$.

Proof. Suppose that p has the property that for every integral closed subscheme $W \subset X$ the map $p|_W : W \rightarrow Y$ is a closed immersion. Then, by definition of capping with $c_1(\mathcal{L})$ the lemma holds.

We will use this remark to reduce to a special case. Namely, write $\alpha = \sum n_i [W_i]$ with $n_i \neq 0$ and W_i pairwise distinct. Let $W'_i \subset Y$ be the image of W_i (as an

integral closed subscheme). Consider the diagram

$$\begin{array}{ccc} X' = \coprod W_i & \xrightarrow{q} & X \\ p' \downarrow & & \downarrow p \\ Y' = \coprod W'_i & \xrightarrow{q'} & Y. \end{array}$$

Since $\{W_i\}$ is locally finite on X , and p is proper we see that $\{W'_i\}$ is locally finite on Y and that q, q', p' are also proper morphisms. We may think of $\sum n_i[W_i]$ also as a k -cycle $\alpha' \in Z_k(X')$. Clearly $q_*\alpha' = \alpha$. We have $q_*(c_1(q^*p^*\mathcal{L}) \cap \alpha') = c_1(p^*\mathcal{L}) \cap q_*\alpha'$ and $(q')_*(c_1((q')^*\mathcal{L}) \cap p'_*\alpha') = c_1(\mathcal{L}) \cap q'_*p'_*\alpha'$ by the initial remark of the proof. Hence it suffices to prove the lemma for the morphism p' and the cycle $\sum n_i[W_i]$. Clearly, this means we may assume X, Y integral, $f : X \rightarrow Y$ dominant and $\alpha = [X]$. In this case the result follows from Lemma 41.25.5. \square

41.26. Cartier divisors and K-groups

In this section we describe how the intersection with the first chern class of an invertible sheaf \mathcal{L} corresponds to tensoring with $\mathcal{L} - \mathcal{O}$ in K -groups.

Lemma 41.26.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let \mathcal{F} be a coherent \mathcal{O}_X -module. Let $s \in \Gamma(X, \mathcal{K}_X(\mathcal{L}))$ be a meromorphic section of \mathcal{L} . Assume*

- (1) $\dim_\delta(X) \leq k + 1$,
- (2) X has no embedded points,
- (3) \mathcal{F} has no embedded associated points,
- (4) the support of \mathcal{F} is X , and
- (5) the section s is regular meromorphic.

In this situation let $\mathcal{I} \subset \mathcal{O}_X$ be the ideal of denominators of s , see Divisors, Definition 30.15.15. Then we have the following:

- (1) *there are short exact sequences*

$$\begin{array}{ccccccc} 0 & \rightarrow & \mathcal{I}\mathcal{F} & \xrightarrow{1} & \mathcal{F} & \rightarrow & \mathcal{Q}_1 \rightarrow 0 \\ 0 & \rightarrow & \mathcal{I}\mathcal{F} & \xrightarrow{s} & \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L} & \rightarrow & \mathcal{Q}_2 \rightarrow 0 \end{array}$$

- (2) *the coherent sheaves $\mathcal{Q}_1, \mathcal{Q}_2$ are supported in δ -dimension $\leq k$,*
- (3) *the section s restricts to a regular meromorphic section s_i on every irreducible component X_i of X of δ -dimension $k + 1$, and*
- (4) *writing $[\mathcal{F}]_{k+1} = \sum m_i[X_i]$ we have*

$$[\mathcal{Q}_2]_k - [\mathcal{Q}_1]_k = \sum m_i(X_i \rightarrow X)_* \operatorname{div}_{\mathcal{L}|_{X_i}}(s_i)$$

in $Z_k(X)$, in particular

$$[\mathcal{Q}_2]_k - [\mathcal{Q}_1]_k = c_1(\mathcal{L}) \cap [\mathcal{F}]_{k+1}$$

in $A_k(X)$.

Proof. Recall from Divisors, Lemma 30.15.16 the existence of injective maps $1 : \mathcal{I}\mathcal{F} \rightarrow \mathcal{F}$ and $s : \mathcal{I}\mathcal{F} \rightarrow \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}$ whose cokernels are supported on a closed nowhere dense subsets T . Denote \mathcal{Q}_i there cokernels as in the lemma. We conclude that $\dim_\delta(\operatorname{Supp}(\mathcal{Q}_i)) \leq k$. By Divisors, Lemmas 30.15.4 and 30.15.12 the pullbacks s_i are defined and are regular meromorphic sections for $\mathcal{L}|_{X_i}$. The equality of cycles

in (4) implies the equality of cycle classes in (4). Hence the only remaining thing to show is that

$$[\mathcal{Q}_2]_k - [\mathcal{Q}_1]_k = \sum m_i(X_i \rightarrow X)_* \operatorname{div}_{\mathcal{L}|_{X_i}}(s_i)$$

holds in $Z_k(X)$. To see this, let $Z \subset X$ be an integral closed subscheme of δ -dimension k . Let $\xi \in Z$ be the generic point. Let $A = \mathcal{O}_{X,\xi}$ and $M = \mathcal{F}_\xi$. Moreover, choose a generator $s_\xi \in \mathcal{L}_\xi$. Then we can write $s = (a/b)s_\xi$ where $a, b \in A$ are nonzerodivisors. In this case $I = \mathcal{I}_\xi = \{x \in A \mid x(a/b) \in A\}$. In this case the coefficient of $[Z]$ in the left hand side is

$$\operatorname{length}_A(M/(a/b)IM) - \operatorname{length}_A(M/IM)$$

and the coefficient of $[Z]$ in the right hand side is

$$\sum \operatorname{length}_{A_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}) \operatorname{ord}_{A/\mathfrak{q}_i}(a/b)$$

where $\mathfrak{q}_1, \dots, \mathfrak{q}_t$ are the minimal primes of the 1-dimensional local ring A . Hence the result follows from Lemma 41.5.7. \square

Lemma 41.26.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let \mathcal{F} be a coherent \mathcal{O}_X -module. Assume $\dim_\delta(\operatorname{Support}(\mathcal{F})) \leq k + 1$. Then the element*

$$[\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{F}] \in K_0(\operatorname{Coh}_{\leq k+1}(X)/\operatorname{Coh}_{\leq k-1}(X))$$

lies in the subgroup $B_k(X)$ of Lemma 41.22.5 and maps to the element $c_1(\mathcal{L}) \cap [\mathcal{F}]_{k+1}$ via the map $B_k(X) \rightarrow A_k(X)$.

Proof. Let

$$0 \rightarrow \mathcal{K} \rightarrow \mathcal{F} \rightarrow \mathcal{F}' \rightarrow 0$$

be the short exact sequence constructed in Divisors, Lemma 30.4.5. This in particular means that \mathcal{F}' has no embedded associated points. Since the support of \mathcal{K} is nowhere dense in the support of \mathcal{F} we see that $\dim_\delta(\operatorname{Supp}(\mathcal{K})) \leq k$. We may re-apply Divisors, Lemma 30.4.5 starting with \mathcal{K} to get a short exact sequence

$$0 \rightarrow \mathcal{K}'' \rightarrow \mathcal{K} \rightarrow \mathcal{K}' \rightarrow 0$$

where now $\dim_\delta(\operatorname{Supp}(\mathcal{K}'')) < k$ and \mathcal{K}' has no embedded associated points. Suppose we can prove the lemma for the coherent sheaves \mathcal{F}' and \mathcal{K}' . Then we see from the equations

$$[\mathcal{F}]_{k+1} = [\mathcal{F}']_{k+1} + [\mathcal{K}']_{k+1} + [\mathcal{K}'']_{k+1}$$

(use Lemma 41.10.4),

$$[\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{F}] = [\mathcal{F}' \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{F}'] + [\mathcal{K}' \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{K}'] + [\mathcal{K}'' \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{K}'']$$

(use the $\otimes \mathcal{L}$ is exact) and the trivial vanishing of $[\mathcal{K}'']_{k+1}$ and $[\mathcal{K}'' \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{K}'']$ in $K_0(\operatorname{Coh}_{\leq k+1}(X)/\operatorname{Coh}_{\leq k-1}(X))$ that the result holds for \mathcal{F} . What this means is that we may assume that the sheaf \mathcal{F} has no embedded associated points.

Assume X, \mathcal{F} as in the lemma, and assume in addition that \mathcal{F} has no embedded associated points. Consider the sheaf of ideals $\mathcal{I} \subset \mathcal{O}_X$, the corresponding closed subscheme $i : Z \rightarrow X$ and the coherent \mathcal{O}_Z -module \mathcal{G} constructed in Divisors, Lemma 30.4.6. Recall that Z is a locally Noetherian scheme without embedded points, \mathcal{G} is a coherent sheaf without embedded associated points, with $\operatorname{Supp}(\mathcal{G}) = Z$ and such that $i_*\mathcal{G} = \mathcal{F}$. Moreover, set $\mathcal{N} = \mathcal{L}|_Z$.

By Divisors, Lemma 30.15.13 the invertible sheaf \mathcal{N} has a regular meromorphic section s over Z . Let us denote $\mathcal{J} \subset \mathcal{O}_Z$ the sheaf of denominators of s . By Lemma 41.26.1 there exist short exact sequences

$$\begin{array}{ccccccc} 0 & \rightarrow & \mathcal{J}\mathcal{G} & \xrightarrow{1} & \mathcal{G} & \rightarrow & \mathcal{Q}_1 \rightarrow 0 \\ 0 & \rightarrow & \mathcal{J}\mathcal{G} & \xrightarrow{s} & \mathcal{G} \otimes_{\mathcal{O}_Z} \mathcal{N} & \rightarrow & \mathcal{Q}_2 \rightarrow 0 \end{array}$$

such that $\dim_\delta(\text{Supp}(\mathcal{Q}_i)) \leq k$ and such that the cycle $[\mathcal{Q}_2]_k - [\mathcal{Q}_1]_k$ is a representative of $c_1(\mathcal{N}) \cap [\mathcal{G}]_{k+1}$. We see (using the fact that $i_*(\mathcal{G} \otimes \mathcal{N}) = \mathcal{F} \otimes \mathcal{L}$ by the projection formula, see Cohomology, Lemma 20.8.2) that

$$[\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{F}] = [i_*\mathcal{Q}_2] - [i_*\mathcal{Q}_1]$$

in $K_0(\text{Coh}_{\leq k+1}(X)/\text{Coh}_{\leq k-1}(X))$. This already shows that $[\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}] - [\mathcal{F}]$ is an element of $B_k(X)$. Moreover we have

$$\begin{aligned} [i_*\mathcal{Q}_2]_k - [i_*\mathcal{Q}_1]_k &= i_*([\mathcal{Q}_2]_k - [\mathcal{Q}_1]_k) \\ &= i_*(c_1(\mathcal{N}) \cap [\mathcal{G}]_{k+1}) \\ &= c_1(\mathcal{L}) \cap i_*[\mathcal{G}]_{k+1} \\ &= c_1(\mathcal{L}) \cap [\mathcal{F}]_{k+1} \end{aligned}$$

by the above and Lemmas 41.25.6 and 41.12.3. And this agree with the image of the element under $B_k(X) \rightarrow A_k(X)$ by definition. Hence the lemma is proved. \square

41.27. Blowing up lemmas

In this section we prove some lemmas on representing Cartier divisors by suitable effective Cartier divisors on blow-ups. These lemmas can be found in [Ful98, Section 2.4]. We have adapted the formulation so they also work in the non-finite type setting. It may happen that the morphism b of Lemma 41.27.7 is a composition of infinitely many blow ups, but over any given quasi-compact open $W \subset X$ one needs only finitely many blow-ups (and this is the result of loc. cit.).

Lemma 41.27.1. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a proper morphism. Let $D \subset Y$ be an effective Cartier divisor. Assume X, Y integral, $n = \dim_\delta(X) = \dim_\delta(Y)$ and f dominant. Then*

$$f_*[f^{-1}(D)]_{n-1} = [R(X) : R(Y)][D]_{n-1}.$$

In particular if f is birational then $f_[f^{-1}(D)]_{n-1} = [D]_{n-1}$.*

Proof. Immediate from Lemma 41.25.5 and the fact that D is the zero scheme of the canonical section 1_D of $\mathcal{O}_X(D)$. \square

Lemma 41.27.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral with $\dim_\delta(X) = n$. Let \mathcal{L} be an invertible \mathcal{O}_X -module. Let s be a nonzero meromorphic section of \mathcal{L} . Let $U \subset X$ be the maximal open subscheme such that s corresponds to a section of \mathcal{L} over U . There exists a projective morphism*

$$\pi : X' \longrightarrow X$$

such that

- (1) X' is integral,
- (2) $\pi|_{\pi^{-1}(U)} : \pi^{-1}(U) \rightarrow U$ is an isomorphism,

(3) there exist effective Cartier divisors $D, E \subset X'$ such that

$$\pi^* \mathcal{L} = \mathcal{O}_{X'}(D - E),$$

(4) the meromorphic section s corresponds, via the isomorphism above, to the meromorphic section $1_D \otimes (1_E)^{-1}$ (see Divisors, Definition 30.9.14),

(5) we have

$$\pi_*([D]_{n-1} - [E]_{n-1}) = \text{div}_{\mathcal{L}}(s)$$

in $Z_{n-1}(X)$.

Proof. Let $\mathcal{I} \subset \mathcal{O}_X$ be the quasi-coherent ideal sheaf of denominators of s . Namely, we declare a local section f of \mathcal{O}_X to be a local section of \mathcal{I} if and only if fs is a local section of \mathcal{L} . On any affine open $U = \text{Spec}(A)$ of X write $\mathcal{L}|_U = \tilde{L}$ for some invertible A -module L . Then A is a Noetherian domain with fraction field $K = R(X)$ and we may think of $s|_U$ as an element of $L \otimes_A K$ (see Divisors, Lemma 30.15.7). Let $I = \{x \in A \mid xs \in L\}$. Then we see that $\mathcal{I}|_U = \tilde{I}$ (details omitted) and hence \mathcal{I} is quasi-coherent.

Consider the closed subscheme $Z \subset X$ defined by \mathcal{I} . It is clear that $U = X \setminus Z$. This suggests we should blow up Z . Let

$$\pi : X' = \text{Proj}_X \left(\bigoplus_{n \geq 0} \mathcal{I}^n \right) \longrightarrow X$$

be the blowing up of X along Z . The quasi-coherent sheaf of \mathcal{O}_X -algebras $\bigoplus_{n \geq 0} \mathcal{I}^n$ is generated in degree 1 over \mathcal{O}_X . Moreover, the degree 1 part is a coherent \mathcal{O}_X -module, in particular of finite type. Hence we see that π is projective and $\mathcal{O}_{X'}(1)$ is relatively very ample.

By Divisors, Lemma 30.18.7 we have X' is integral. By Divisors, Lemma 30.18.4 there exists an effective Cartier divisor $E \subset X'$ such that $\pi^{-1}\mathcal{I} \cdot \mathcal{O}_{X'} = \mathcal{I}_E$. Also, by the same lemma we see that $\pi^{-1}(U) \cong U$.

Denote s' the pullback of the meromorphic section s to a meromorphic section of $\mathcal{L}' = \pi^* \mathcal{L}$ over X' . It follows from the fact that $\mathcal{I}s \subset \mathcal{L}$ that $\mathcal{I}_E s' \subset \mathcal{L}'$. In other words, s' gives rise to an $\mathcal{O}_{X'}$ -linear map $\mathcal{I}_E \rightarrow \mathcal{L}'$, or in other words a section $t \in \mathcal{L}' \otimes \mathcal{O}_{X'}(E)$. By Divisors, Lemma 30.9.20 we obtain a unique effective Cartier divisor $D \subset X'$ such that $\mathcal{L}' \otimes \mathcal{O}_{X'}(E) \cong \mathcal{O}_{X'}(D)$ with t corresponding to 1_D . Reversing this procedure we conclude that $\mathcal{L}' = \mathcal{O}_{X'}(-E) \cong \mathcal{O}_{X'}(D)$ with s' corresponding to $1_D \otimes 1_E^{-1}$ as in (4).

We still have to prove (5). By Lemma 41.25.5 we have

$$\pi_*(\text{div}_{\mathcal{L}'}(s')) = \text{div}_{\mathcal{L}}(s).$$

Hence it suffices to show that $\text{div}_{\mathcal{L}'}(s') = [D]_{n-1} - [E]_{n-1}$. This follows from the equality $s' = 1_D \otimes 1_E^{-1}$ and additivity, see Lemma 41.24.3. \square

Definition 41.27.3. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_{\delta}(X) = n$. Let D_1, D_2 be two effective Cartier divisors in X . Let $Z \subset X$ be an integral closed subscheme with $\dim_{\delta}(Z) = n - 1$. The ϵ -invariant of this situation is

$$\epsilon_Z(D_1, D_2) = n_Z \cdot m_Z$$

where n_Z , resp. m_Z is the coefficient of Z in the $(n-1)$ -cycle $[D_1]_{n-1}$, resp. $[D_2]_{n-1}$.

Lemma 41.27.4. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = n$. Let D_1, D_2 be two effective Cartier divisors in X . Let Z be an open and closed subscheme of the scheme $D_1 \cap D_2$. Assume $\dim_\delta(D_1 \cap D_2 \setminus Z) \leq n - 2$. Then there exists a morphism $b : X' \rightarrow X$, and Cartier divisors D'_1, D'_2, E on X' with the following properties*

- (1) X' is integral,
- (2) b is projective,
- (3) b is the blow up of X in the closed subscheme Z ,
- (4) $E = b^{-1}(Z)$,
- (5) $b^{-1}(D_1) = D'_1 + E$, and $b^{-1}D_2 = D'_2 + E$,
- (6) $\dim_\delta(D'_1 \cap D'_2) \leq n - 2$, and if $Z = D_1 \cap D_2$ then $D'_1 \cap D'_2 = \emptyset$,
- (7) for every integral closed subscheme W' with $\dim_\delta(W') = n - 1$ we have
 - (a) if $\epsilon_{W'}(D'_1, E) > 0$, then setting $W = b(W')$ we have $\dim_\delta(W) = n - 1$ and

$$\epsilon_{W'}(D'_1, E) < \epsilon_W(D_1, D_2),$$

- (b) if $\epsilon_{W'}(D'_2, E) > 0$, then setting $W = b(W')$ we have $\dim_\delta(W) = n - 1$ and

$$\epsilon_{W'}(D'_2, E) < \epsilon_W(D_1, D_2),$$

Proof. Note that the quasi-coherent ideal sheaf $\mathcal{I} = \mathcal{I}_{D_1} + \mathcal{I}_{D_2}$ defines the scheme theoretic intersection $D_1 \cap D_2 \subset X$. Since Z is a union of connected components of $D_1 \cap D_2$ we see that for every $z \in Z$ the kernel of $\mathcal{O}_{X,z} \rightarrow \mathcal{O}_{Z,z}$ is equal to \mathcal{I}_z . Let $b : X' \rightarrow X$ be the blow up of X in Z . (So Zariski locally around Z it is the blow up of X in \mathcal{I} .) Denote $E = b^{-1}(Z)$ the corresponding effective Cartier divisor, see Divisors, Lemma 30.18.4. Since $Z \subset D_1$ we have $E \subset f^{-1}(D_1)$ and hence $D_1 = D'_1 + E$ for some effective Cartier divisor $D'_1 \subset X'$, see Divisors, Lemma 30.9.8. Similarly $D_2 = D'_2 + E$. This takes care of assertions (1) – (5).

Note that if W' is as in (7) (a) or (7) (b), then the image W of W' is contained in $D_1 \cap D_2$. If W is not contained in Z , then b is an isomorphism at the generic point of W and we see that $\dim_\delta(W) = \dim_\delta(W') = n - 1$ which contradicts the assumption that $\dim_\delta(D_1 \cap D_2 \setminus Z) \leq n - 2$. Hence $W \subset Z$. This means that to prove (6) and (7) we may work locally around Z on X .

Thus we may assume that $X = \text{Spec}(A)$ with A a Noetherian domain, and $D_1 = \text{Spec}(A/a)$, $D_2 = \text{Spec}(A/b)$ and $Z = D_1 \cap D_2$. Set $I = (a, b)$. Since A is a domain and $a, b \neq 0$ we can cover the blow up by two patches, namely $U = \text{Spec}(A[s]/(as - b))$ and $V = \text{Spec}(A[t]/(bt - a))$. These patches are glued using the isomorphism $A[s, s^{-1}]/(as - b) \cong A[t, t^{-1}]/(bt - a)$ which maps s to t^{-1} . The effective Cartier divisor E is described by $\text{Spec}(A[s]/(as - b, a)) \subset U$ and $\text{Spec}(A[t]/(bt - a, b)) \subset V$. The closed subscheme D'_1 corresponds to $\text{Spec}(A[t]/(bt - a, t)) \subset U$. The closed subscheme D'_2 corresponds to $\text{Spec}(A[s]/(as - b, s)) \subset V$. Since “ $ts = 1$ ” we see that $D'_1 \cap D'_2 = \emptyset$.

Suppose we have a prime $\mathfrak{q} \subset A[s]/(as - b)$ of height one with $s, a \in \mathfrak{q}$. Let $\mathfrak{p} \subset A$ be the corresponding prime of A . Observe that $a, b \in \mathfrak{p}$. By the dimension formula we see that $\dim(A_{\mathfrak{p}}) = 1$ as well. The final assertion to be shown is that

$$\text{ord}_{A_{\mathfrak{p}}}(a)\text{ord}_{A_{\mathfrak{p}}}(b) > \text{ord}_{B_{\mathfrak{q}}}(a)\text{ord}_{B_{\mathfrak{q}}}(s)$$

where $B = A[s]/(as - b)$. By Algebra, Lemma 10.120.1 we have $\text{ord}_{A_p}(x) \geq \text{ord}_{B_q}(x)$ for $x = a, b$. Since $\text{ord}_{B_q}(s) > 0$ we win by additivity of the ord function and the fact that $as = b$. \square

Definition 41.27.5. Let X be a scheme. Let $\{D_i\}_{i \in I}$ be a locally finite collection of effective Cartier divisors on X . Suppose given a function $I \rightarrow \mathbf{Z}_{\geq 0}$, $i \mapsto n_i$. The sum of the effective Cartier divisors $D = \sum n_i D_i$, is the unique effective Cartier divisor $D \subset X$ such that on any quasi-compact open $U \subset X$ we have $D|_U = \sum_{D_i \cap U \neq \emptyset} n_i D_i|_U$ is the sum as in Divisors, Definition 30.9.6.

Lemma 41.27.6. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = n$. Let $\{D_i\}_{i \in I}$ be a locally finite collection of effective Cartier divisors on X . Suppose given $n_i \geq 0$ for $i \in I$. Then

$$[D]_{n-1} = \sum_i n_i [D_i]_{n-1}$$

in $Z_{n-1}(X)$.

Proof. Since we are proving an equality of cycles we may work locally on X . Hence this reduces to a finite sum, and by induction to a sum of two effective Cartier divisors $D = D_1 + D_2$. By Lemma 41.24.2 we see that $D_1 = \text{div}_{\mathcal{O}_X(D_1)}(1_{D_1})$ where 1_{D_1} denotes the canonical section of $\mathcal{O}_X(D_1)$. Of course we have the same statement for D_2 and D . Since $1_D = 1_{D_1} \otimes 1_{D_2}$ via the identification $\mathcal{O}_X(D) = \mathcal{O}_X(D_1) \otimes \mathcal{O}_X(D_2)$ we win by Lemma 41.24.3. \square

Lemma 41.27.7. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = d$. Let $\{D_i\}_{i \in I}$ be a locally finite collection of effective Cartier divisors on X . Assume that for all $\{i, j, k\} \subset I$, $\#\{i, j, k\} = 3$ we have $D_i \cap D_j \cap D_k = \emptyset$. Then there exist

- (1) an open subscheme $U \subset X$ with $\dim_\delta(X \setminus U) \leq d - 3$,
- (2) a morphism $b : U' \rightarrow U$, and
- (3) effective Cartier divisors $\{D'_j\}_{j \in J}$ on U'

with the following properties:

- (1) b is proper morphism $b : U' \rightarrow U$,
- (2) U' is integral,
- (3) b is an isomorphism over the complement of the union of the pairwise intersections of the $D_i|_U$,
- (4) $\{D'_j\}_{j \in J}$ is a locally finite collection of effective Cartier divisors on U' ,
- (5) $\dim_\delta(D'_j \cap D'_{j'}) \leq d - 2$ if $j \neq j'$, and
- (6) $b^{-1}(D_i|_U) = \sum n_{ij} D'_j$ for certain $n_{ij} \geq 0$.

Moreover, if X is quasi-compact, then we may assume $U = X$ in the above.

Proof. Let us first prove this in the quasi-compact case, since it is perhaps the most interesting case. In this case we produce inductively a sequence of blowups

$$X = X_0 \xleftarrow{b_0} X_1 \xleftarrow{b_1} X_2 \leftarrow \dots$$

and finite sets of effective Cartier divisors $\{D_{n,i}\}_{i \in I_n}$. At each stage these will have the property that any triple intersection $D_{n,i} \cap D_{n,j} \cap D_{n,k}$ is empty. Moreover, for each $n \geq 0$ we will have $I_{n+1} = I_n \amalg P(I_n)$ where $P(I_n)$ denotes the set of pairs of elements of I_n . Finally, we will have

$$b_n^{-1}(D_{n,i}) = D_{n+1,i} + \sum_{i' \in I_n, i' \neq i} D_{n+1,\{i,i'\}}$$

We conclude that for each $n \geq 0$ we have $(b_0 \circ \dots \circ b_n)^{-1}(D_i)$ is a nonnegative integer combination of the divisors $D_{n+1,j}$, $j \in I_{n+1}$.

To start the induction we set $X_0 = X$ and $I_0 = I$ and $D_{0,i} = D_i$.

Given $(X_n, \{D_{n,i}\}_{i \in I_n})$ let X_{n+1} be the blow up of X_n in the closed subscheme $Z_n = \bigcup_{\{i,i'\} \in P(I_n)} D_{n,i} \cap D_{n,i'}$. Note that the closed subschemes $D_{n,i} \cap D_{n,i'}$ are pairwise disjoint by our assumption on triple intersections. In other words we may write $Z_n = \prod_{\{i,i'\} \in P(I_n)} D_{n,i} \cap D_{n,i'}$. Moreover, in a Zariski neighbourhood of $D_{n,i} \cap D_{n,i'}$ the morphism b_n is equal to the blow up of the scheme X_n in the closed subscheme $D_{n,i} \cap D_{n,i'}$, and the results of Lemma 41.27.4 apply. Hence setting $D_{n+1,\{i,i'\}} = b_n^{-1}(D_i \cap D_{i'})$ we get an effective Cartier divisor. The Cartier divisors $D_{n+1,\{i,i'\}}$ are pairwise disjoint. Clearly we have $b_n^{-1}(D_{n,i}) \supset D_{n+1,\{i,i'\}}$ for every $i' \in I_n$, $i' \neq i$. Hence, applying Divisors, Lemma 30.9.8 we see that indeed $b^{-1}(D_{n,i}) = D_{n+1,i} + \sum_{i' \in I_n, i' \neq i} D_{n+1,\{i,i'\}}$ for some effective Cartier divisor $D_{n+1,i}$ on X_{n+1} . In a neighbourhood of $D_{n+1,\{i,i'\}}$ these divisors $D_{n+1,i}$ play the role of the primed divisors of Lemma 41.27.4. In particular we conclude that $D_{n+1,i} \cap D_{n+1,i'} = \emptyset$ if $i \neq i'$, $i, i' \in I_n$ by part (6) of Lemma 41.27.4. This already implies that triple intersections of the divisors $D_{n+1,i}$ are zero.

OK, and at this point we can use the quasi-compactness of X to conclude that the invariant

$$(41.27.7.1)$$

$$\epsilon(X, \{D_i\}_{i \in I}) = \max\{\epsilon_Z(D_i, D_{i'}) \mid Z \subset X, \dim_\delta(Z) = d - 1, \{i, i'\} \in P(I)\}$$

is finite, since after all each D_i has at most finitely many irreducible components. We claim that for some n the invariant $\epsilon(X_n, \{D_{n,i}\}_{i \in I_n})$ is zero. Namely, if not then by Lemma 41.27.4 we have a strictly decreasing sequence

$$\epsilon(X, \{D_i\}_{i \in I}) = \epsilon(X_0, \{D_{0,i}\}_{i \in I_0}) > \epsilon(X_1, \{D_{1,i}\}_{i \in I_1}) > \dots$$

of positive integers which is a contradiction. Take n with invariant $\epsilon(X_n, \{D_{n,i}\}_{i \in I_n})$ equal to zero. This means that there is no integral closed subscheme $Z \subset X_n$ and no pair of indices $i, i' \in I_n$ such that $\epsilon_Z(D_{n,i}, D_{n,i'}) > 0$. In other words, $\dim_\delta(D_{n,i}, D_{n,i'}) \leq d - 2$ for all pairs $\{i, i'\} \in P(I_n)$ as desired.

Next, we come to the general case where we no longer assume that the scheme X is quasi-compact. The problem with the idea from the first part of the proof is that we may get an infinite sequence of blow ups with centers dominating a fixed point of X . In order to avoid this we cut out suitable closed subsets of codimension ≥ 3 at each stage. Namely, we will construct by induction a sequence of morphisms having the following shape

$$\begin{array}{c} X = X_0 \\ \uparrow j_0 \\ U_0 \longleftarrow^{b_0} X_1 \\ \uparrow j_1 \\ U_1 \longleftarrow^{b_1} X_2 \\ \uparrow j_2 \\ U_2 \longleftarrow^{b_2} X_3 \end{array}$$

Each of the morphisms $j_n : U_n \rightarrow X_n$ will be an open immersion. Each of the morphisms $b_n : X_{n+1} \rightarrow U_n$ will be a proper birational morphism of integral schemes. As in the quasi-compact case we will have effective Cartier divisors $\{D_{n,i}\}_{i \in I_n}$ on X_n . At each stage these will have the property that any triple intersection $D_{n,i} \cap D_{n,j} \cap D_{n,k}$ is empty. Moreover, for each $n \geq 0$ we will have $I_{n+1} = I_n \amalg P(I_n)$ where $P(I_n)$ denotes the set of pairs of elements of I_n . Finally, we will arrange it so that

$$b_n^{-1}(D_{n,i}|_{U_n}) = D_{n+1,i} + \sum_{i' \in I_n, i' \neq i} D_{n+1,\{i,i'\}}$$

We start the induction by setting $X_0 = X$, $I_0 = I$ and $D_{0,i} = D_i$.

Given $(X_n, \{D_{n,i}\})$ we construct the open subscheme U_n as follows. For each pair $\{i, i'\} \in P(I_n)$ consider the closed subscheme $D_{n,i} \cap D_{n,i'}$. This has “good” irreducible components which have δ -dimension $d-2$ and “bad” irreducible components which have δ -dimension $d-1$. Let us set

$$\text{Bad}(i, i') = \bigcup_{W \subset D_{n,i} \cap D_{n,i'} \text{ irred. comp. with } \dim_\delta(W)=d-1} W$$

and similarly

$$\text{Good}(i, i') = \bigcup_{W \subset D_{n,i} \cap D_{n,i'} \text{ irred. comp. with } \dim_\delta(W)=d-2} W.$$

Then $D_{n,i} \cap D_{n,i'} = \text{Bad}(i, i') \cup \text{Good}(i, i')$ and moreover we have $\dim_\delta(\text{Bad}(i, i') \cap \text{Good}(i, i')) \leq d-3$. Here is our choice of U_n :

$$U_n = X_n \setminus \bigcup_{\{i,i'\} \in P(I_n)} \text{Bad}(i, i') \cap \text{Good}(i, i').$$

By our condition on triple intersections of the divisors $D_{n,i}$ we see that the union is actually a disjoint union. Moreover, we see that (as a scheme)

$$D_{n,i}|_{U_n} \cap D_{n,i'}|_{U_n} = Z_{n,i,i'} \amalg G_{n,i,i'}$$

where $Z_{n,i,i'}$ is δ -equidimensional of dimension $d-1$ and $G_{n,i,i'}$ is δ -equidimensional of dimension $d-2$. (So topologically $Z_{n,i,i'}$ is the union of the bad components but throw out intersections with good components.) Finally we set

$$Z_n = \bigcup_{\{i,i'\} \in P(I_n)} Z_{n,i,i'} = \amalg_{\{i,i'\} \in P(I_n)} Z_{n,i,i'},$$

and we let $b_n : X_{n+1} \rightarrow X_n$ be the blow up in Z_n . Note that Lemma 41.27.4 applies to the morphism $b_n : X_{n+1} \rightarrow X_n$ locally around each of the loci $D_{n,i}|_{U_n} \cap D_{n,i'}|_{U_n}$. Hence, exactly as in the first part of the proof we obtain effective Cartier divisors $D_{n+1,\{i,i'\}}$ for $\{i, i'\} \in P(I_n)$ and effective Cartier divisors $D_{n+1,i}$ for $i \in I_n$ such that $b_n^{-1}(D_{n,i}|_{U_n}) = D_{n+1,i} + \sum_{i' \in I_n, i' \neq i} D_{n+1,\{i,i'\}}$. For each n denote $\pi_n : X_n \rightarrow X$ the morphism obtained as the composition $j_0 \circ \dots \circ j_{n-1} \circ b_{n-1}$.

Claim: given any quasi-compact open $V \subset X$ for all sufficiently large n the maps

$$\pi_n^{-1}(V) \leftarrow \pi_{n+1}^{-1}(V) \leftarrow \dots$$

are all isomorphisms. Namely, if the map $\pi_n^{-1}(V) \leftarrow \pi_{n+1}^{-1}(V)$ is not an isomorphism, then $Z_{n,i,i'} \cap \pi_n^{-1}(V) \neq \emptyset$ for some $\{i, i'\} \in P(I_n)$. Hence there exists an irreducible component $W \subset D_{n,i} \cap D_{n,i'}$ with $\dim_\delta(W) = d-1$. In particular we see that $\epsilon_W(D_{n,i}, D_{n,i'}) > 0$. Applying Lemma 41.27.4 repeatedly we see that

$$\epsilon_W(D_{n,i}, D_{n,i'}) < \epsilon(V, \{D_i|_V\}) - n$$

with $\epsilon(V, \{D_i|_V\})$ as in (41.27.7.1). Since V is quasi-compact, we have $\epsilon(V, \{D_i|_V\}) < \infty$ and taking $n > \epsilon(V, \{D_i|_V\})$ we see the result.

Note that by construction the difference $X_n \setminus U_n$ has $\dim_\delta(X_n \setminus U_n) \leq d - 3$. Let $T_n = \pi_n(X_n \setminus U_n)$ be its image in X . Traversing in the diagram of maps above using each b_n is closed it follows that $T_0 \cup \dots \cup T_n$ is a closed subset of X for each n . Any $t \in T_n$ satisfies $\delta(t) \leq d - 3$ by construction. Hence $\overline{T_n} \subset X$ is a closed subset with $\dim_\delta(T_n) \leq d - 3$. By the claim above we see that for any quasi-compact open $V \subset X$ we have $T_n \cap V \neq \emptyset$ for at most finitely many n . Hence $\{\overline{T_n}\}_{n \geq 0}$ is a locally finite collection of closed subsets, and we may set $U = X \setminus \bigcup \overline{T_n}$. This will be U as in the lemma.

Note that $U_n \cap \pi_n^{-1}(U) = \pi_n^{-1}(U)$ by construction of U . Hence all the morphisms

$$b_n : \pi_{n+1}^{-1}(U) \longrightarrow \pi_n^{-1}(U)$$

are proper. Moreover, by the claim they eventually become isomorphisms over each quasi-compact open of X . Hence we can define

$$U' = \lim_n \pi_n^{-1}(U).$$

The induced morphism $b : U' \rightarrow U$ is proper since this is local on U , and over each compact open the limit stabilizes. Similarly we set $J = \bigcup_{n \geq 0} I_n$ using the inclusions $I_n \rightarrow I_{n+1}$ from the construction. For $j \in J$ choose an n_0 such that j corresponds to $i \in I_{n_0}$ and define $D'_j = \lim_{n \geq n_0} D_{n,i}$. Again this makes sense as locally over X the morphisms stabilize. The other claims of the lemma are verified as in the case of a quasi-compact X . □

41.28. Intersecting with effective Cartier divisors

To be able to prove the commutativity of intersection products we need a little more precision in terms of supports of the cycles. Here is the relevant notion.

Definition 41.28.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let D be an effective Cartier divisor on X , and denote $i : D \rightarrow X$ the closed immersion. We define, for every integer k , a *Gysin homomorphism*

$$i^* : Z_{k+1}(X) \rightarrow A_k(D).$$

- (1) Given a integral closed subscheme $W \subset X$ with $\dim_\delta(W) = k + 1$ we define
 - (a) if $W \not\subset D$, then $i^*[W] = [D \cap W]_k$ as a k -cycle on D , and
 - (b) if $W \subset D$, then $i^*[W] = i'_*(c_1(\mathcal{O}_X(D)|_W) \cap [W])$, where $i' : W \rightarrow D$ is the induced closed immersion.
- (2) For a general $(k + 1)$ -cycle $\alpha = \sum n_j [W_j]$ we set

$$i^* \alpha = \sum n_j i^*[W_j]$$

- (3) We denote $D \cdot \alpha = i_* i^* \alpha$ the pushforward of the class to a class on X .

In fact, as we will see later, this Gysin homomorphism i^* can be viewed as an example of a non-flat pullback. Thus we will sometimes informally call the class $i^* \alpha$ the *pullback* of the class α .

Lemma 41.28.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let D be an effective Cartier divisor on X . Let α be a $(k + 1)$ -cycle on X . Then $D \cdot \alpha = c_1(\mathcal{O}_X(D)) \cap \alpha$ in $A_k(X)$.*

Proof. Write $\alpha = \sum n_j[W_j]$ where $i_j : W_j \rightarrow X$ are integral closed subschemes with $\dim_\delta(W_j) = k$. Since D is the zero scheme of the canonical section 1_D of $\mathcal{O}_X(D)$ we see that $D \cap W_j$ is the zero scheme of the restriction $1_D|_{W_j}$. Hence for each j such that $W_j \not\subset D$ we have $c_1(\mathcal{O}_X(D)) \cap [W_j] = [D \cap W_j]_k$ by Lemma 41.25.3. So we have

$$c_1(\mathcal{O}_X(D)) \cap \alpha = \sum_{W_j \not\subset D} n_j [D \cap W_j]_k + \sum_{W_j \subset D} n_j i_{j,*}(c_1(\mathcal{O}_X(D)|_{W_j}) \cap [W_j])$$

in $A_k(X)$ by Definition 41.25.1. The right hand side matches (termwise) the push-forward of the class $i^*\alpha$ on D from Definition 41.28.1. Hence we win. \square

The following lemma will be superseded later.

Lemma 41.28.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let D be an effective Cartier divisor on X . Let $W \subset X$ be a closed subscheme such that $D' = W \cap D$ is an effective Cartier divisor on W .*

$$\begin{array}{ccc} D' & \xrightarrow{\quad} & W \\ i'' \downarrow & & \downarrow i' \\ D & \xrightarrow{\quad} & X \end{array}$$

For any $(k + 1)$ -cycle on W we have $i^*\alpha = (i'')_*(i')^*\alpha$ in $A_k(D)$.

Proof. Suppose $\alpha = [Z]$ for some integral closed subscheme $Z \subset W$. In case $Z \not\subset D$ we have $Z \cap D' = Z \cap D$ scheme theoretically. Hence the equality holds as cycles. In case $Z \subset D$ we also have $Z \subset D'$ and the equality holds since $\mathcal{O}_X(D)|_Z \cong \mathcal{O}_W(D')|_Z$ and the definition of i^* and $(i')^*$ in these cases. \square

Lemma 41.28.4. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $i : D \rightarrow X$ be an effective Cartier divisor on X .*

- (1) *Let $Z \subset X$ be a closed subscheme such that $\dim_\delta(Z) \leq k + 1$ and such that $D \cap Z$ is an effective Cartier divisor on Z . Then $i^*[Z]_{k+1} = [D \cap Z]_k$.*
- (2) *Let \mathcal{F} be a coherent sheaf on X such that $\dim_\delta(\text{Support}(\mathcal{F})) \leq k + 1$ and $1_D : \mathcal{F} \rightarrow \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_X(D)$ is injective. Then*

$$i^*[\mathcal{F}]_{k+1} = [i^*\mathcal{F}]_k$$

in $A_k(D)$.

Proof. Assume $Z \subset X$ as in (1). Then set $\mathcal{F} = \mathcal{O}_Z$. The assumption that $D \cap Z$ is an effective Cartier divisor is equivalent to the assumption that $1_D : \mathcal{F} \rightarrow \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_X(D)$ is injective. Moreover $[Z]_{k+1} = [\mathcal{F}]_{k+1}$ and $[D \cap Z]_k = [\mathcal{O}_{D \cap Z}]_k = [i^*\mathcal{F}]_k$. See Lemma 41.10.3. Hence part (1) follows from part (2).

Write $[\mathcal{F}]_{k+1} = \sum m_j[W_j]$ with $m_j > 0$ and pairwise distinct integral closed subschemes $W_j \subset X$ of δ -dimension $k + 1$. The assumption that $1_D : \mathcal{F} \rightarrow \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_X(D)$ is injective implies that $W_j \not\subset D$ for all j . By definition we see that

$$i^*[\mathcal{F}]_{k+1} = \sum [D \cap W_j]_k.$$

We claim that

$$\sum [D \cap W_j]_k = [i^*\mathcal{F}]_k$$

as cycles. Let $Z \subset D$ be an integral closed subscheme of δ -dimension k . Let $\xi \in Z$ be its generic point. Let $A = \mathcal{O}_{X, \xi}$. Let $M = \mathcal{F}_\xi$. Let $f \in A$ be an

element generating the ideal of D , i.e., such that $\mathcal{O}_{D,\xi} = A/fA$. By assumption $\dim(M) = 1$, $f : M \rightarrow M$ is injective, and $\text{length}_A(M/fM) < \infty$. Moreover, $\text{length}_A(M/fM)$ is the coefficient of $[Z]$ in $[i^*\mathcal{F}]_k$. On the other hand, let $\mathfrak{q}_1, \dots, \mathfrak{q}_t$ be the minimal primes in the support of M . Then

$$\sum \text{length}_{A_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}) \text{ord}_{A/\mathfrak{q}_i}(f)$$

is the coefficient of $[Z]$ in $\sum [D \cap W_j]_k$. Hence we see the equality by Lemma 41.5.6. \square

Lemma 41.28.5. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $\{i_j : D_j \rightarrow X\}_{j \in J}$ be a locally finite collection of effective Cartier divisors on X . Let $n_j > 0$, $j \in J$. Set $D = \sum_{j \in J} n_j D_j$, and denote $i : D \rightarrow X$ the inclusion morphism. Let $\alpha \in Z_{k+1}(X)$. Then*

$$p : \prod_{j \in J} D_j \longrightarrow D$$

is proper and

$$i^* \alpha = p_* \left(\sum n_j i_j^* \alpha \right)$$

in $A_k(D)$.

Proof. The proof of this lemma is made a bit longer than expected by a subtlety concerning infinite sums of rational equivalences. In the quasi-compact case the family D_j is finite and the result is altogether easy and a straightforward consequence of Lemmas 41.24.2 and 41.24.3 and the definitions.

The morphism p is proper since the family $\{D_j\}_{j \in J}$ is locally finite. Write $\alpha = \sum_{a \in A} m_a [W_a]$ with $W_a \subset X$ an integral closed subscheme of δ -dimension $k + 1$. Denote $i_a : W_a \rightarrow X$ the closed immersion. We assume that $m_a \neq 0$ for all $a \in A$ such that $\{W_a\}_{a \in A}$ is locally finite on X .

Observe that by Definition 41.28.1 the class $i^* \alpha$ is the class of a cycle $\sum m_a \beta_a$ for certain $\beta_a \in Z_k(W_a \cap D)$. Namely, if $W_a \not\subset D$ then $\beta_a = [D \cap W_a]_k$ and if $W_a \subset D$, then β_a is a cycle representing $c_1(\mathcal{O}_X(D)) \cap [W_a]$.

For each $a \in A$ write $J = J_{a,1} \amalg J_{a,2} \amalg J_{a,3}$ where

- (1) $j \in J_{a,1}$ if and only if $W_a \cap D_j = \emptyset$,
- (2) $j \in J_{a,2}$ if and only if $W_a \neq W_a \cap D_1 \neq \emptyset$, and
- (3) $j \in J_{a,3}$ if and only if $W_a \subset D_j$.

Since the family $\{D_j\}$ is locally finite we see that $J_{a,3}$ is a finite set. For every $a \in A$ and $j \in J$ we choose a cycle $\beta_{a,j} \in Z_k(W_a \cap D_j)$ as follows

- (1) if $j \in J_{a,1}$ we set $\beta_{a,j} = 0$,
- (2) if $j \in J_{a,2}$ we set $\beta_{a,j} = [D_j \cap W_a]_k$, and
- (3) if $j \in J_{a,3}$ we choose $\beta_{a,j} \in Z_k(W_a)$ representing $c_1(i_a^* \mathcal{O}_X(D_j)) \cap [W_j]$.

We claim that

$$\beta_a \sim_{\text{rat}} \sum_{j \in J} n_j \beta_{a,j}$$

in $A_k(W_a \cap D)$.

Case I: $W_a \not\subset D$. In this case $J_{a,3} = \emptyset$. Thus it suffices to show that $[D \cap W_a]_k = \sum n_j [D_j \cap W_a]_k$ as cycles. This is Lemma 41.27.6.

Case II: $W_a \subset D$. In this case β_a is a cycle representing $c_1(i_a^* \mathcal{O}_X(D)) \cap [W_a]$. Write $D = D_{a,1} + D_{a,2} + D_{a,3}$ with $D_{a,s} = \sum_{j \in J_{a,s}} n_j D_j$. By Lemma 41.24.3 we have

$$c_1(i_a^* \mathcal{O}_X(D)) \cap [W_a] = c_1(i_a^* \mathcal{O}_X(D_{a,1})) \cap [W_a] + c_1(i_a^* \mathcal{O}_X(D_{a,2})) \cap [W_a] + c_1(i_a^* \mathcal{O}_X(D_{a,3})) \cap [W_a].$$

It is clear that the first term of the sum is zero. Since $J_{a,3}$ is finite we see that the last term agrees with $\sum_{j \in J_{a,3}} n_j c_1(i_a^* \mathcal{L}_j) \cap [W_a]$, see Lemma 41.24.3. This is represented by $\sum_{j \in J_{a,3}} n_j \beta_{a,j}$. Finally, by Case I we see that the middle term is represented by the cycle $\sum_{j \in J_{a,2}} n_j [D_j \cap W_a]_k = \sum_{j \in J_{a,2}} n_j \beta_{a,j}$. Whence the claim in this case.

At this point we are ready to finish the proof of the lemma. Namely, we have $i^* D \sim_{rat} \sum m_a \beta_a$ by our choice of β_a . For each a we have $\beta_a \sim_{rat} \sum_j \beta_{a,j}$ with the rational equivalence taking place on $D \cap W_a$. Since the collection of closed subschemes $D \cap W_a$ is locally finite on D , we see that also $\sum m_a \beta_a \sim_{rat} \sum_{a,j} m_a \beta_{a,j}$ on D ! (See Remark 41.19.4.) Ok, and now it is clear that $\sum_a m_a \beta_{a,j}$ (viewed as a cycle on D_j) represents $i_j^* \alpha$ and hence $\sum_{a,j} m_a \beta_{a,j}$ represents $p_* \sum_j i_j^* \alpha$ and we win. \square

Lemma 41.28.6. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = n$. Let D, D' be effective Cartier divisors on X . Assume $\dim_\delta(D \cap D') = n - 2$. Let $i : D \rightarrow X$, resp. $i' : D' \rightarrow X$ be the corresponding closed immersions. Then*

- (1) *there exists a cycle $\alpha \in Z_{n-2}(D \cap D')$ whose pushforward to D represents $i^*[D']_{n-1} \in A_{n-2}(D)$ and whose pushforward to D' represents $(i')^*[D]_{n-1} \in A_{n-2}(D')$, and*
- (2) *we have*

$$D \cdot [D']_{n-1} = D' \cdot [D]_{n-1}$$

in $A_{n-2}(X)$.

Proof. Part (2) is a trivial consequence of part (1). Let us write $[D]_{n-1} = \sum n_a [Z_a]$ and $[D']_{n-1} = \sum m_b [Z_b]$ with Z_a the irreducible components of D and $[Z_b]$ the irreducible components of D' . According to Definition 41.28.1, we have $i^* D' = \sum m_b i^* [Z_b]$ and $(i')^* D = \sum n_a (i')^* [Z_a]$. By assumption, none of the irreducible components Z_b is contained in D , and hence $i^* [Z_b] = [Z_b \cap D]_{n-2}$ by definition. Similarly $(i')^* [Z_a] = [Z_a \cap D']_{n-2}$. Hence we are trying to prove the equality of cycles

$$\sum n_a [Z_a \cap D']_{n-2} = \sum m_b [Z_b \cap D]_{n-2}$$

which are indeed supported on $D \cap D'$. Let $W \subset X$ be an integral closed subscheme with $\dim_\delta(W) = n - 2$. Let $\xi \in W$ be its generic point. Set $R = \mathcal{O}_{X,\xi}$. It is a Noetherian local domain. Note that $\dim(R) = 2$. Let $f \in R$, resp. $f' \in R$ be an element defining the ideal of D , resp. D' . By assumption $\dim(R/(f, f')) = 0$. Let $\mathfrak{q}'_1, \dots, \mathfrak{q}'_t \subset R$ be the minimal primes over (f') , let $\mathfrak{q}_1, \dots, \mathfrak{q}_s \subset R$ be the minimal primes over (f) . The equality above comes down to the equality

$$\sum_{i=1, \dots, s} \text{length}_{R_{\mathfrak{q}_i}}(R_{\mathfrak{q}_i}/(f)) \text{ord}_{R/\mathfrak{q}_i}(f') = \sum_{j=1, \dots, t} \text{length}_{R_{\mathfrak{q}'_j}}(R_{\mathfrak{q}'_j}/(f')) \text{ord}_{R/\mathfrak{q}'_j}(f).$$

By Lemma 41.5.5 applied with $M = R/(f)$ the left hand side of this equation is equal to

$$\text{length}_R(R/(f, f')) - \text{length}_R(\text{Ker}(f' : R/(f) \rightarrow R/(ff')))$$

OK, and now we note that $\text{Ker}(f' : R/(f) \rightarrow R/(ff'))$ is canonically isomorphic to $((f) \cap (f'))/(ff')$ via the map $x \text{ mod } (f) \mapsto f'x \text{ mod } (ff')$. Hence the left hand side is

$$\text{length}_R(R/(f, f')) - \text{length}_R((f) \cap (f'))/(ff')$$

Since this is symmetric in f and f' we win. □

Lemma 41.28.7. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = n$. Let $\{D_j\}_{j \in J}$ be a locally finite collection of effective Cartier divisors on X . Let $n_j, m_j \geq 0$ be collections of nonnegative integers. Set $D = \sum n_j D_j$ and $D' = \sum m_j D_j$. Assume that $\dim_\delta(D_j \cap D_{j'}) = n - 2$ for every $j \neq j'$. Then $D \cdot [D']_{n-1} = D' \cdot [D]_{n-1}$ in $A_{n-2}(X)$.*

Proof. This lemma is a trivial consequence of Lemmas 41.27.6 and 41.28.6 in case the sums are finite, e.g., if X is quasi-compact. Hence we suggest the reader skip the proof.

Here is the proof in the general case. Let $i_j : D_j \rightarrow X$ be the closed immersions. Let $p : \coprod D_j \rightarrow X$ denote coproduct of the morphisms i_j . Let $\{Z_a\}_{a \in A}$ be the collection of irreducible components of $\bigcup D_j$. For each j we write

$$[D_j]_{n-1} = \sum d_{j,a} [Z_a].$$

By Lemma 41.27.6 we have

$$[D]_{n-1} = \sum n_j d_{j,a} [Z_a], \quad [D']_{n-1} = \sum m_j d_{j,a} [Z_a].$$

By Lemma 41.28.5 we have

$$D \cdot [D']_{n-1} = p_* \left(\sum n_j i_j^* [D']_{n-1} \right), \quad D' \cdot [D]_{n-1} = p_* \left(\sum m_{j'} i_{j'}^* [D]_{n-1} \right).$$

As in the definition of the Gysin homomorphisms (see Definition 41.28.1) we choose cycles $\beta_{a,j}$ on $D_j \cap Z_a$ representing $i_j^* [Z_a]$. (Note that in fact $\beta_{a,j} = [D_j \cap Z_a]_{n-2}$ if Z_a is not contained in D_j , i.e., there is no choice in that case.) Now since p is a closed immersion when restricted to each of the D_j we can (and we will) view $\beta_{a,j}$ as a cycle on X . Plugging in the formulas for $[D]_{n-1}$ and $[D']_{n-1}$ obtained above we see that

$$D \cdot [D']_{n-1} = \sum_{j,j',a} n_j m_{j'} d_{j',a} \beta_{a,j}, \quad D' \cdot [D]_{n-1} = \sum_{j,j',a} m_{j'} n_j d_{j,a} \beta_{a,j'}.$$

Moreover, with the same conventions we also have

$$D_j \cdot [D_{j'}]_{n-1} = \sum d_{j',a} \beta_{a,j}.$$

In these terms Lemma 41.28.6 (see also its proof) says that for $j \neq j'$ the cycles $\sum d_{j',a}\beta_{a,j}$ and $\sum d_{j,a}\beta_{a,j'}$ are equal as cycles! Hence we see that

$$\begin{aligned} D \cdot [D']_{n-1} &= \sum_{j,j',a} n_j m_{j'} d_{j',a} \beta_{a,j} \\ &= \sum_{j \neq j'} n_j m_{j'} \left(\sum_a d_{j',a} \beta_{a,j} \right) + \sum_{j,a} n_j m_j d_{j,a} \beta_{a,j} \\ &= \sum_{j \neq j'} n_j m_{j'} \left(\sum_a d_{j,a} \beta_{a,j'} \right) + \sum_{j,a} n_j m_j d_{j,a} \beta_{a,j} \\ &= \sum_{j,j',a} m_{j'} n_j d_{j,a} \beta_{a,j'} \\ &= D' \cdot [D]_{n-1} \end{aligned}$$

and we win. \square

Here is the key lemma of this chapter. A stronger version of this lemma asserts that $D \cdot [D']_{n-1} = D' \cdot [D]_{n-1}$ holds in $A_{n-2}(D \cap D')$ for suitable representatives of the dot products involved. The first proof of the lemma together with Lemmas 41.28.5, 41.28.6, and 41.28.7 can be modified to show this (see [Ful98]). It is not so clear how to modify the second proof to prove the refined version. An application of the refined version is a proof that the Gysin homomorphism factors through rational equivalence. We will show this by another method later.

Lemma 41.28.8. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = n$. Let D, D' be effective Cartier divisors on X . Then*

$$D \cdot [D']_{n-1} = D' \cdot [D]_{n-1}$$

in $A_{n-2}(X)$.

First proof of Lemma 41.28.8. First, let us prove this in case X is quasi-compact. In this case, apply Lemma 41.27.7 to X and the two element set $\{D, D'\}$ of effective Cartier divisors. Thus we get a proper morphism $b : X' \rightarrow X$, a finite collection of effective Cartier divisors $D'_j \subset X'$ intersecting pairwise in codimension ≥ 2 , with $b^{-1}(D) = \sum n_j D'_j$, and $b^{-1}(D') = \sum m_j D'_j$. Note that $b_*[b^{-1}(D)]_{n-1} = [D]_{n-1}$ in $Z_{n-1}(X)$ and similarly for D' , see Lemma 41.27.1. Hence, by Lemma 41.25.6 we have

$$D \cdot [D']_{n-1} = b_* (b^{-1}(D) \cdot [b^{-1}(D')]_{n-1})$$

in $A_{n-2}(X)$ and similarly for the other term. Hence the lemma follows from the equality $b^{-1}(D) \cdot [b^{-1}(D')]_{n-1} = b^{-1}(D') \cdot [b^{-1}(D)]_{n-1}$ in $A_{n-2}(X')$ of Lemma 41.28.7.

Note that in the proof above, each referenced lemma works also in the general case (when X is not assumed quasi-compact). The only minor change in the general case is that the morphism $b : U' \rightarrow U$ we get from applying Lemma 41.27.7 has as its target an open $U \subset X$ whose complement has codimension ≥ 3 . Hence by Lemma 41.19.2 we see that $A_{n-2}(U) = A_{n-2}(X)$ and after replacing X by U the rest of the proof goes through unchanged. \square

Second proof of Lemma 41.28.8. Let $\mathcal{I} = \mathcal{O}_X(-D)$ and $\mathcal{I}' = \mathcal{O}_X(-D')$ be the invertible ideal sheaves of D and D' . We denote $\mathcal{I}_{D'} = \mathcal{I} \otimes_{\mathcal{O}_X} \mathcal{O}_{D'}$ and $\mathcal{I}'_D = \mathcal{I}' \otimes_{\mathcal{O}_X} \mathcal{O}_D$. We can restrict the inclusion map $\mathcal{I} \rightarrow \mathcal{O}_X$ to D' to get a map

$$\varphi : \mathcal{I}_{D'} \longrightarrow \mathcal{O}_{D'}$$

and similarly

$$\psi : \mathcal{I}'_D \longrightarrow \mathcal{O}_D$$

It is clear that

$$\text{Coker}(\varphi) \cong \mathcal{O}_{D \cap D'} \cong \text{Coker}(\psi)$$

and

$$\text{Ker}(\varphi) \cong \frac{\mathcal{I} \cap \mathcal{I}'}{\mathcal{I}\mathcal{I}'} \cong \text{Ker}(\psi).$$

Hence we see that

$$\gamma = [\mathcal{I}_{D'}] - [\mathcal{O}_{D'}] = [\mathcal{I}'_D] - [\mathcal{O}_D]$$

in $K_0(\text{Coh}_{\leq n-1}(X))$. On the other hand it is clear that

$$[\mathcal{I}'_D]_{n-1} = [D]_{n-1}, \quad [\mathcal{I}_{D'}]_{n-1} = [D']_{n-1}.$$

and that

$$\mathcal{O}_X(D') \otimes \mathcal{I}'_D = \mathcal{O}_D, \quad \mathcal{O}_X(D) \otimes \mathcal{I}_{D'} = \mathcal{O}_{D'}.$$

By Lemma 41.26.2 (applied two times) this means that the element γ is an element of $B_{n-2}(X)$, and maps to both $c_1(\mathcal{O}_X(D')) \cap [D]_{n-1}$ and to $c_1(\mathcal{O}_X(D)) \cap [D']_{n-1}$ and we win (since the map $B_{n-2}(X) \rightarrow A_{n-2}(X)$ is well defined – which is the key to this proof). \square

41.29. Commutativity

At this point we can start using the material above and start proving more interesting results.

Lemma 41.29.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X integral and $\dim_\delta(X) = n$. Let \mathcal{L}, \mathcal{N} be invertible on X . Choose a nonzero meromorphic section s of \mathcal{L} and a nonzero meromorphic section t of \mathcal{N} . Set $\alpha = \text{div}_{\mathcal{L}}(s)$ and $\beta = \text{div}_{\mathcal{N}}(t)$. Then*

$$c_1(\mathcal{N}) \cap \alpha = c_1(\mathcal{L}) \cap \beta$$

in $A_{n-2}(X)$.

Proof. By Lemma 41.27.2 (applied twice) there exists a proper morphism $\pi : X' \rightarrow X$ and effective Cartier divisors D_1, E_1, D_2, E_2 on X' such that

$$b^*\mathcal{L} = \mathcal{O}_{X'}(D_1 - E_1), \quad b^*\mathcal{N} = \mathcal{O}_{X'}(D_2 - E_2),$$

and such that

$$\alpha = \pi_*([D_1]_{n-1} - [E_1]_{n-1}), \quad \beta = \pi_*([D_2]_{n-1} - [E_2]_{n-1}).$$

By the projection formula of Lemma 41.25.6 and the additivity of Lemma 41.25.2 it is enough to show the equality

$$c_1(\mathcal{O}_{X'}(D_1)) \cap [D_2]_{n-1} = c_1(\mathcal{O}_{X'}(D_2)) \cap [D_1]_{n-1}$$

and three other similar equalities involving D_i and E_j . By Lemma 41.28.2 this is the same as showing that $D_1 \cdot [D_2]_{n-1} = D_2 \cdot [D_1]_{n-1}$ and so on. Thus the result follows from Lemma 41.28.8. \square

Lemma 41.29.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L} be invertible on X . The operation $\alpha \mapsto c_1(\mathcal{L}) \cap \alpha$ factors through rational equivalence to give an operation*

$$c_1(\mathcal{L}) \cap - : A_{k+1}(X) \rightarrow A_k(X)$$

Proof. Let $\alpha \in Z_{k+1}(X)$, and $\alpha \sim_{rat} 0$. We have to show that $c_1(\mathcal{L}) \cap \alpha$ as defined in Definition 41.25.1 is zero. By Definition 41.19.1 there exists a locally finite family $\{W_j\}$ of integral closed subschemes with $\dim_\delta(W_j) = k + 2$ and rational functions $f_j \in R(W_j)^*$ such that

$$\alpha = \sum (i_j)_* \operatorname{div}_{W_j}(f_j)$$

Note that $p : \coprod W_j \rightarrow X$ is a proper morphism, and hence $\alpha = p_* \alpha'$ where $\alpha' \in Z_{k+1}(\coprod W_j)$ is the sum of the principal divisors $\operatorname{div}_{W_j}(f_j)$. By the projection formula (Lemma 41.25.6) we have $c_1(\mathcal{L}) \cap \alpha = p_*(c_1(p^* \mathcal{L}) \cap \alpha')$. Hence it suffices to show that each $c_1(\mathcal{L}|_{W_j}) \cap \operatorname{div}_{W_j}(f_j)$ is zero. In other words we may assume that X is integral and $\alpha = \operatorname{div}_X(f)$ for some $f \in R(X)^*$.

Assume X is integral and $\alpha = \operatorname{div}_X(f)$ for some $f \in R(X)^*$. We can think of f as a regular meromorphic section of the invertible sheaf $\mathcal{N} = \mathcal{O}_X$. Choose a meromorphic section s of \mathcal{L} and denote $\beta = \operatorname{div}_{\mathcal{L}}(s)$. By Lemma 41.29.1 we conclude that

$$c_1(\mathcal{L}) \cap \alpha = c_1(\mathcal{O}_X) \cap \beta.$$

However, by Lemma 41.25.2 we see that the right hand side is zero in $A_k(X)$ as desired. \square

For any integer $s \geq 0$ we will denote

$$c_1(\mathcal{L})^s \cap - : A_{k+s}(X) \rightarrow A_k(X)$$

the s -fold iterate of the operation $c_1(\mathcal{L}) \cap -$. This makes sense by the lemma above.

Lemma 41.29.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L}, \mathcal{N} be invertible on X . For any $\alpha \in A_{k+2}(X)$ we have*

$$c_1(\mathcal{L}) \cap c_1(\mathcal{N}) \cap \alpha = c_1(\mathcal{N}) \cap c_1(\mathcal{L}) \cap \alpha$$

as elements of $A_k(X)$.

Proof. Write $\alpha = \sum m_j [Z_j]$ for some locally finite collection of integral closed subschemes $Z_j \subset X$ with $\dim_\delta(Z_j) = k + 2$. Consider the proper morphism $p : \coprod Z_j \rightarrow X$. Set $\alpha' = \sum m_j [Z_j]$ as a $(k + 2)$ -cycle on $\coprod Z_j$. By several applications of Lemma 41.25.6 we see that $c_1(\mathcal{L}) \cap c_1(\mathcal{N}) \cap \alpha = p_*(c_1(p^* \mathcal{L}) \cap c_1(p^* \mathcal{N}) \cap \alpha')$ and $c_1(\mathcal{N}) \cap c_1(\mathcal{L}) \cap \alpha = p_*(c_1(p^* \mathcal{N}) \cap c_1(p^* \mathcal{L}) \cap \alpha')$. Hence it suffices to prove the formula in case X is integral and $\alpha = [X]$. In this case the result follows from Lemma 41.29.1 and the definitions. \square

41.30. Gysin homomorphisms

We want to show the Gysin homomorphisms factor through rational equivalence. One method (see [Ful98]) is to prove a more precise version of the key Lemma 41.28.8 keeping track of supports. Having obtained this one can find analogues of the lemmas of Section 41.29 for the Gysin homomorphism and get the result. We will use another method.

Lemma 41.30.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let X be integral and $n = \dim_\delta(X)$. Let $a \in \Gamma(X, \mathcal{O}_X)$ be a nonzero function. Let $i : D = Z(a) \rightarrow X$ be the closed immersion of the zero scheme of a . Let $f \in R(X)^*$. In this case $i^* \operatorname{div}_X(f) = 0$ in $A_{n-2}(D)$.*

Proof. Write $\text{div}_X(f) = \sum n_j[Z_j]$ for some integral closed subschemes $Z_j \subset X$ of δ -dimension $n - 1$. We may assume that the family $\{Z_j\}_{j \in J}$ is locally finite and that $f \in \Gamma(U, \mathcal{O}_U^*)$ where $U = X \setminus \bigcup Z_j$ (see Lemma 41.16.3 and its proof).

Write $J = J_1 \amalg J_2$ where $J_1 = \{j \in J \mid Z_j \subset D\}$. Note that $\mathcal{O}_X(D) \cong \mathcal{O}_X$ because a^{-1} is a trivializing global section. Hence by Definition 41.28.1 of i^* we see that $i^*\text{div}_X(f)$ is represented by

$$\sum_{j \in J_2} n_j[D \cap Z_j]_{n-2}.$$

Namely, the terms involving $c_1(\mathcal{O}_X(D)|_{Z_j}) \cap Z_j$ may be dropped since $c_1(\mathcal{O}) \cap -$ is the zero operation anyway (see Lemma 41.25.2).

For each j let $\xi_j \in Z_j$ be its generic point. Let $B_j = \mathcal{O}_{X, \xi_j}$, which has residue field $\kappa_j = \kappa(\xi_j) = R(Z_j)$. For $j \in J_1$, let

$$f_j = d_{B_j}(f, a)$$

be the tame symbol, see Definition 41.4.5. We claim that we have the following equality of cycles

$$\sum_{j \in J_2} n_j[D \cap Z_j]_{n-2} = \sum_{j \in J_1} (Z_j \rightarrow D)_* \text{div}_{Z_j}(f_j)$$

on D . Indeed, note that $[D \cap Z_j]_{n-2} = \text{div}_{Z_j}(a)$. Hence $n_j[D \cap Z_j]_{n-2} = \text{div}_{Z_j}(a^{n_j})$. Since $n_j = \text{ord}_{B_j}(f)$ we see that in fact also $n_j[D \cap Z_j]_{n-2} = \text{div}_{Z_j}(d_{B_j}(a, f))$, as a is a unit in B_j see Lemma 41.4.6. Note that $d_{B_j}(f, a) = d_{B_j}(a, f)^{-1}$, see Lemma 41.4.4. Hence altogether we are trying to show that

$$\sum_{j \in J} (Z_j \rightarrow D)_* \text{div}_{Z_j}(d_{B_j}(a, f)) = 0$$

as an $(n - 2)$ -cycle. Consider any codimension 2 integral closed subscheme $W \subset X$ with generic point $\zeta \in X$. Set $A = \mathcal{O}_{X, \zeta}$. Applying Lemma 41.6.1 to (A, a, f) we see that the coefficient of $[W]$ in the expression above is zero as desired. \square

Lemma 41.30.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let X be integral and $n = \dim_\delta(X)$. Let $i : D \rightarrow X$ be an effective Cartier divisor. Let $f \in R(X)^*$. In this case $i^*\text{div}_X(f) = 0$ in $A_{n-2}(D)$.*

Proof. This proof is a repeat of the proof of Lemma 41.30.1. So make sure you've read that one first.

Write $\text{div}_X(f) = \sum n_j[Z_j]$ for some integral closed subschemes $Z_j \subset X$ of δ -dimension $n - 1$. We may assume that the family $\{Z_j\}_{j \in J}$ is locally finite and that $f \in \Gamma(U, \mathcal{O}_U^*)$ where $U = X \setminus \bigcup Z_j$ (see Lemma 41.16.3 and its proof).

Write $J = J_1 \amalg J_2$ where $J_1 = \{j \in J \mid Z_j \subset D\}$. For each j let $\xi_j \in Z_j$ be its generic point. Let us write $\mathcal{L} = \mathcal{O}_X(D)$. Choose $\tilde{s}_j \in \mathcal{L}_{\xi_j}$ a generator. Denote $s_j \in \mathcal{L}_{\xi_j} \otimes \kappa(\xi_j)$ the corresponding nonzero meromorphic section of $\mathcal{L}|_{Z_j}$. Then by Definition 41.28.1 of i^* we see that $i^*\text{div}_X(f)$ is represented by the cycle

$$\sum_{j \in J_2} n_j[D \cap Z_j]_{n-2} + \sum_{j \in J_2} n_j \text{div}_{\mathcal{L}|_{Z_j}}(s_j)$$

on D . Our goal is to show that this is rationally equivalent to zero on D .

Let $B_j = \mathcal{O}_{X, \xi_j}$, which has residue field $\kappa_j = \kappa(\xi_j) = R(Z_j)$. Write $s = a_j \tilde{s}_j$ for some $a_j \in B_j$. For $j \in J_1$ let

$$f_j = d_{B_j}(f, a_j) \in \kappa_j^* = R(Z_j)^*$$

be the tame symbol, see Definition 41.4.5. We claim that we have the following equality of cycles

$$\sum_{j \in J_2} n_j [D \cap Z_j]_{n-2} + \sum_{j \in J_2} n_j \operatorname{div}_{\mathcal{L}|_{Z_j}}(s_j) = \sum_{j \in J_1} (Z_j \rightarrow D)_* \operatorname{div}_{Z_j}(f_j)$$

on D . This will clearly prove the lemma.

Note that for $j \in J_2$ we have $[D \cap Z_j]_{n-2} = \operatorname{div}_{\mathcal{L}|_{Z_j}}(s|_{Z_j})$. Since $s|_{Z_j} = a_j|_{Z_j} s_j$ we see that $[D \cap Z_j]_{n-2} = \operatorname{div}_{\mathcal{L}|_{Z_j}}(s_j) + \operatorname{div}_{Z_j}(a_j|_{Z_j})$. Hence, still for $j \in J_2$, we have

$$n_j [D \cap Z_j]_{n-2} = n_j \operatorname{div}_{\mathcal{L}|_{Z_j}}(s_j) + \operatorname{div}_{Z_j}((a_j|_{Z_j})^{n_j})$$

Since $n_j = \operatorname{ord}_{B_j}(f)$ we see that $\operatorname{div}_{Z_j}((a_j|_{Z_j})^{n_j}) = \operatorname{div}_{Z_j}(d_{B_j}(a_j, f))$, as a_j is a unit in B_j (since $j \in J_2$), see Lemma 41.4.6. Note that $d_{B_j}(f, a_j) = d_{B_j}(a_j, f)^{-1}$, see Lemma 41.4.4. Hence altogether we are trying to show that

$$(41.30.2.1) \quad \sum_{j \in J} n_j \operatorname{div}_{\mathcal{L}|_{Z_j}}(s_j) = \sum_{j \in J} (Z_j \rightarrow D)_* \operatorname{div}_{Z_j}(d_{B_j}(a_j, f))$$

as an $(n - 2)$ -cycle.

Consider any codimension 2 integral closed subscheme $W \subset X$ with generic point $\zeta \in X$. Set $A = \mathcal{O}_{X, \zeta}$. Choose a generator $s_\zeta \in \mathcal{L}_\zeta$. For those j such that $\zeta \in Z_j$ we may write $\tilde{s}_j = b_j s_\zeta$ with $b_j \in B_j^*$. We may also write $s = a_\zeta s_\zeta$ for some $a_\zeta \in A$. Then we see that $a_j = b_j a_\zeta$. The coefficient of $[W]$ on the right hand side of Equation (41.30.2.1) is

$$\sum_{\zeta \in Z_j} n_j \operatorname{ord}_{A/\mathfrak{q}_j}(\overline{b_j}).$$

where $\mathfrak{q}_j \subset A$ is the height one prime corresponding to Z_j . Note that $B_j = A_{\mathfrak{q}_j}$ in this case. The coefficient of $[W]$ on the left hand side of Equation (41.30.2.1) is

$$\sum_{\zeta \in Z_j} \operatorname{ord}_{A/\mathfrak{q}_j}(d_{A_{\mathfrak{q}_j}}(b_j a_\zeta, f)).$$

Since b_j is a unit, and $n_j = \operatorname{ord}_{A_{\mathfrak{q}_j}}(f)$ we see that $d_{A_{\mathfrak{q}_j}}(b_j a_\zeta, f) = \overline{b_j}^{n_j} d_{A_{\mathfrak{q}_j}}(a_\zeta, f)$ by Lemmas 41.4.4 and 41.4.6. By additivity of ord we see that it suffices to prove

$$0 = \sum_{\zeta \in Z_j} \operatorname{ord}_{A/\mathfrak{q}_j}(d_{A_{\mathfrak{q}_j}}(a_\zeta, f))$$

which is Lemma 41.6.1. □

Lemma 41.30.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let $i : D \rightarrow X$ be an effective Cartier divisor on X . The Gysin homomorphism factors through rational equivalence to give a map $i^* : A_{k+1}(X) \rightarrow A_k(D)$.*

Proof. Let $\alpha \in Z_{k+1}(X)$ and assume that $\alpha \sim_{\text{rat}} 0$. This means there exists a locally finite collection of integral closed subschemes $W_j \subset X$ of δ -dimension $k + 2$ and $f_j \in R(W_j)^*$ such that $\alpha = \sum i_{j,*} \operatorname{div}_{W_j}(f_j)$. By construction of the map i^* we see that $i^* \alpha = \sum i^* i_{j,*} \operatorname{div}_{W_j}(f_j)$ where each cycle $i^* i_{j,*} \operatorname{div}_{W_j}(f_j)$ is supported on $D \cap W_j$. If we can show that each $i^* i_{j,*} \operatorname{div}_{W_j}(f_j)$ is rationally equivalent on $W_j \cap D$, then we see that $i^* \alpha \sim_{\text{rat}} 0$ (this is clear if the sum is finite, in general see Remark 41.19.4).

Pick an index j . If $W_j \subset D$, then we see that $i^* i_{j,*} \operatorname{div}_{W_j}(f_j)$ is simply equal to

$$i'_{j,*} c_1(\mathcal{O}_X(D)|_{W_j}) \cap \operatorname{div}_{W_j}(f_j)$$

where $i'_j : W_j \rightarrow D$ is the inclusion map. This is rationally equivalent to zero by Lemma 41.29.2. If $W_j \not\subset D$, then we see that $i^*i_{j,*}\text{div}_{W_j}(f_j)$ is simply equal to

$$(i')^*\text{div}_{W_j}(f_j)$$

where $i' : D \cap W_j \rightarrow W_j$ is the corresponding closed immersion (see Lemma 41.28.3). Hence in this case Lemma 41.30.2 applies, and we win. \square

41.31. Relative effective Cartier divisors

Lemma 41.31.1. *Let $A \rightarrow B$ be a ring map. Let $f \in B$. Assume that*

- (1) $A \rightarrow B$ is flat,
- (2) f is a nonzerodivisor, and
- (3) $A \rightarrow B/fB$ is flat.

Then for every ideal $I \subset A$ the map $f : B/IB \rightarrow B/IB$ is injective.

Proof. Note that $IB = I \otimes_A B$ and $I(B/fB) = I \otimes_A B/fB$ by the flatness of B and B/fB over A . In particular $IB/fIB \cong I \otimes_A B/fB$ maps injectively into B/fB . Hence the result follows from the snake lemma applied to the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & I \otimes_A B & \longrightarrow & B & \longrightarrow & B/IB & \longrightarrow & 0 \\ & & \downarrow f & & \downarrow f & & \downarrow f & & \\ 0 & \longrightarrow & I \otimes_A B & \longrightarrow & B & \longrightarrow & B/IB & \longrightarrow & 0 \end{array}$$

with exact rows. \square

Lemma 41.31.2. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $p : X \rightarrow Y$ be a flat morphism of relative dimension r . Let $i : D \rightarrow X$ be an effective Cartier divisor with the property that $p|_D : D \rightarrow Y$ is flat of relative dimension $r - 1$. Let $\mathcal{L} = \mathcal{O}_X(D)$. For any $\alpha \in A_{k+1}(Y)$ we have*

$$i^*p^*\alpha = (p|_D)^*\alpha$$

in $A_{k+r}(D)$ and

$$c_1(\mathcal{L}) \cap p^*\alpha = i_*((p|_D)^*\alpha)$$

in $A_{k+r}(X)$.

Proof. Let $W \subset Y$ be an integral closed subvariety of δ -dimension $k + 1$. By Lemma 41.31.1 we see that $D \cap p^{-1}W$ is an effective Cartier divisor on $p^{-1}W$. By Lemma 41.28.4 we see that $i^*[p^{-1}W]_{k+r+1} = [D \cap W]_{k+r} = [(p|_D)^{-1}(W)]_{k+r}$. Since by definition $p^*[W] = [p^{-1}W]_{k+r+1}$ and $(p|_D)^*[W] = [(p|_D)^{-1}(W)]_{k+r}$ we see we have equality of cycles. Hence if $\alpha = \sum m_j[W_j]$, then we get $i^*\alpha = \sum m_j i^*[W_j] = \sum m_j (p|_D)^*[W_j]$ as cycles. This proves then first equality. To deduce the second from the first apply Lemma 41.28.2. \square

41.32. Affine bundles

Lemma 41.32.1. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r . Assume that for every $y \in Y$, there exists an open neighbourhood $U \subset Y$ such that $f|_{f^{-1}(U)} : f^{-1}(U) \rightarrow U$ is identified with the morphism $U \times \mathbf{A}^r \rightarrow U$. Then $f^* : A_k(Y) \rightarrow A_{k+r}(X)$ is surjective for all $k \in \mathbf{Z}$.*

Proof. Let $\alpha \in A_{k+r}(X)$. Write $\alpha = \sum m_j[W_j]$ with $m_j \neq 0$ and W_j pairwise distinct integral closed subschemes of δ -dimension $k + r$. Then the family $\{W_j\}$ is locally finite in X . For any quasi-compact open $V \subset Y$ we see that $f^{-1}(V) \cap W_j$ is nonempty only for finitely many j . Hence the collection $Z_j = \overline{f^{-1}(V) \cap W_j}$ of closures of images is a locally finite collection of integral closed subschemes of Y .

Consider the fibre product diagrams

$$\begin{array}{ccc} f^{-1}(Z_j) & \longrightarrow & X \\ f_j \downarrow & & \downarrow f \\ Z_j & \longrightarrow & Y \end{array}$$

Suppose that $[W_j] \in Z_{k+r}(f^{-1}(Z_j))$ is rationally equivalent to $f_j^* \beta_j$ for some k -cycle $\beta_j \in A_k(Z_j)$. Then $\beta = \sum m_j \beta_j$ will be a k -cycle on Y and $f^* \beta = \sum m_j f_j^* \beta_j$ will be rationally equivalent to α (see Remark 41.19.4). This reduces us to the case Y integral, and $\alpha = [W]$ for some integral closed subscheme of X dominating Y . In particular we may assume that $d = \dim_\delta(Y) < \infty$.

Hence we can use induction on $d = \dim_\delta(Y)$. If $d < k$, then $A_{k+r}(X) = 0$ and the lemma holds. By assumption there exists a dense open $V \subset Y$ such that $f^{-1}(V) \cong V \times \mathbf{A}^r$ as schemes over V . Suppose that we can show that $\alpha|_{f^{-1}(V)} = f^* \beta$ for some $\beta \in Z_k(V)$. By Lemma 41.14.2 we see that $\beta = \beta'|_V$ for some $\beta' \in Z_k(Y)$. By the exact sequence $A_k(f^{-1}(Y \setminus V)) \rightarrow A_k(X) \rightarrow A_k(f^{-1}(V))$ of Lemma 41.19.2 we see that $\alpha - f^* \beta'$ comes from a cycle $\alpha' \in A_{k+r}(f^{-1}(Y \setminus V))$. Since $\dim_\delta(Y \setminus V) < d$ we win by induction on d .

Thus we may assume that $X = Y \times \mathbf{A}^r$. In this case we can factor f as

$$X = Y \times \mathbf{A}^r \rightarrow Y \times \mathbf{A}^{r-1} \rightarrow \dots \rightarrow Y \times \mathbf{A}^1 \rightarrow Y.$$

Hence it suffices to do the case $r = 1$. By the argument in the second paragraph of the proof we are reduced to the case $\alpha = [W]$, Y integral, and $W \rightarrow Y$ dominant. Again we can do induction on $d = \dim_\delta(Y)$. If $W = Y \times \mathbf{A}^1$, then $[W] = f^*[Y]$. Lastly, $W \subset Y \times \mathbf{A}^1$ is a proper inclusion, then $W \rightarrow Y$ induces a finite field extension $R(Y) \subset R(W)$. Let $P(T) \in R(Y)[T]$ be the monic irreducible polynomial such that the generic fibre of $W \rightarrow Y$ is cut out by P in $\mathbf{A}^1_{R(Y)}$. Let $V \subset Y$ be a nonempty open such that $P \in \Gamma(V, \mathcal{O}_Y)[T]$, and such that $W \cap f^{-1}(V)$ is still cut out by P . Then we see that $\alpha|_{f^{-1}(V)} \sim_{rat} 0$ and hence $\alpha \sim_{rat} \alpha'$ for some cycle α' on $(Y \setminus V) \times \mathbf{A}^1$. By induction on the dimension we win. \square

Remark 41.32.2. We will see later (Lemma 41.33.3) that if X is a vectorbundle over Y then the pullback map $A_k(Y) \rightarrow A_{k+r}(X)$ is an isomorphism. Is this true in general?

41.33. Projective space bundle formula

Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Consider a finite locally free \mathcal{O}_X -module \mathcal{E} of rank r . Our convention is that the *projective bundle associated to \mathcal{E}* is the morphism

$$\mathbf{P}(\mathcal{E}) = \text{Proj}_X(\text{Sym}^*(\mathcal{E})) \xrightarrow{\pi} X$$

over X with $\mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)$ normalized so that $\pi_*(\mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)) = \mathcal{E}$. In particular there is a surjection $\pi^*\mathcal{E} \rightarrow \mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)$. We will say informally “let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ be the projective bundle associated to \mathcal{E} ” to denote the situation where $P = \mathbf{P}(\mathcal{E})$ and $\mathcal{O}_P(1) = \mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)$.

Lemma 41.33.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free \mathcal{O}_X -module \mathcal{E} of rank r . Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ be the projective bundle associated to \mathcal{E} . For any $\alpha \in A_k(X)$ the element*

$$\pi_*(c_1(\mathcal{O}_P(1))^s \cap \pi^*\alpha) \in A_{k+r-1-s}(X)$$

is 0 if $s < r - 1$ and is equal to α when $s = r - 1$.

Proof. Let $Z \subset X$ be an integral closed subscheme of δ -dimension k . Note that $\pi^*[Z] = [\pi^{-1}(Z)]$ as $\pi^{-1}(Z)$ is integral of δ -dimension $r - 1$. If $s < r - 1$, then by construction $c_1(\mathcal{O}_P(1))^s \cap \pi^*[Z]$ is represented by a $(k + r - 1 - s)$ -cycle supported on $\pi^{-1}(Z)$. Hence the pushforward of this cycle is zero for dimension reasons.

Let $s = r - 1$. By the argument given above we see that $\pi_*(c_1(\mathcal{O}_P(1))^s \cap \pi^*\alpha) = n[Z]$ for some $n \in \mathbf{Z}$. We want to show that $n = 1$. For the same dimension reasons as above it suffices to prove this result after replacing X by $X \setminus T$ where $T \subset Z$ is a proper closed subset. Let ξ be the generic point of Z . We can choose elements $e_1, \dots, e_{r-1} \in \mathcal{E}_\xi$ which form part of a basis of \mathcal{E}_ξ . These give rational sections s_1, \dots, s_{r-1} of $\mathcal{O}_P(1)|_{\pi^{-1}(Z)}$ whose common zero set is the closure of the image a rational section of $\mathbf{P}(\mathcal{E}|_Z) \rightarrow Z$ union a closed subset whose support maps to a proper closed subset T of Z . After removing T from X (and correspondingly $\pi^{-1}(T)$ from P), we see that s_1, \dots, s_n form a sequence of global sections $s_i \in \Gamma(\pi^{-1}(Z), \mathcal{O}_{\pi^{-1}(Z)}(1))$ whose common zero set is the image of a section $Z \rightarrow \pi^{-1}(Z)$. Hence we see successively that

$$\begin{aligned} \pi^*[Z] &= [\pi^{-1}(Z)] \\ c_1(\mathcal{O}_P(1)) \cap \pi^*[Z] &= [Z(s_1)] \\ c_1(\mathcal{O}_P(1))^2 \cap \pi^*[Z] &= [Z(s_1) \cap Z(s_2)] \\ &\dots = \dots \\ c_1(\mathcal{O}_P(1))^{r-1} \cap \pi^*[Z] &= [Z(s_1) \cap \dots \cap Z(s_{r-1})] \end{aligned}$$

by repeated applications of Lemma 41.25.3. Since the pushforward by π of the image of a section of π over Z is clearly $[Z]$ we see the result when $\alpha = [Z]$. We omit the verification that these arguments imply the result for a general cycle $\alpha = \sum n_j[Z_j]$. \square

Lemma 41.33.2 (Projective space bundle formula). *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free \mathcal{O}_X -module \mathcal{E} of rank r . Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ be the projective bundle associated to \mathcal{E} . The map*

$$\bigoplus_{i=0}^{r-1} A_{k+i}(X) \longrightarrow A_{k+r-1}(P),$$

$$(\alpha_0, \dots, \alpha_{r-1}) \longmapsto \pi^*\alpha_0 + c_1(\mathcal{O}_P(1)) \cap \pi^*\alpha_1 + \dots + c_1(\mathcal{O}_P(1))^{r-1} \cap \pi^*\alpha_{r-1}$$

is an isomorphism.

Proof. Fix $k \in \mathbf{Z}$. We first show the map is injective. Suppose that $(\alpha_0, \dots, \alpha_{r-1})$ is an element of the left hand side that maps to zero. By Lemma 41.33.1 we see that

$$0 = \pi_*(\pi^*\alpha_0 + c_1(\mathcal{O}_P(1)) \cap \pi^*\alpha_1 + \dots + c_1(\mathcal{O}_P(1))^{r-1} \cap \pi^*\alpha_{r-1}) = \alpha_{r-1}$$

Next, we see that

$$0 = \pi_*(c_1(\mathcal{O}_P(1)) \cap (\pi^*\alpha_0 + c_1(\mathcal{O}_P(1)) \cap \pi^*\alpha_1 + \dots + c_1(\mathcal{O}_P(1))^{r-2} \cap \pi^*\alpha_{r-2})) = \alpha_{r-2}$$

and so on. Hence the map is injective.

It remains to show the map is surjective. Let $X_i, i \in I$ be the irreducible components of X . Then $P_i = \mathbf{P}(\mathcal{E}|_{X_i}), i \in I$ are the irreducible components of P . If the map is surjective for each of the morphisms $P_i \rightarrow X_i$, then the map is surjective for $\pi : P \rightarrow X$. Details omitted. Hence we may assume X is irreducible. Thus $\dim_\delta(X) < \infty$ and in particular we may use induction on $\dim_\delta(X)$.

The result is clear if $\dim_\delta(X) < k$. Let $\alpha \in A_{k+r-1}(P)$. For any locally closed subscheme $T \subset X$ denote $\gamma_T : \bigoplus A_{k+i}(T) \rightarrow A_{k+r-1}(\pi^{-1}(T))$ the map

$$\gamma_T(\alpha_0, \dots, \alpha_{r-1}) = \pi^*\alpha_0 + \dots + c_1(\mathcal{O}_{\pi^{-1}(T)}(1))^{r-1} \cap \pi^*\alpha_{r-1}.$$

Suppose for some nonempty open $U \subset X$ we have $\alpha|_{\pi^{-1}(U)} = \gamma_U(\alpha_0, \dots, \alpha_{r-1})$. Then we may choose lifts $\alpha'_i \in A_{k+i}(X)$ and we see that $\alpha - \gamma_X(\alpha'_0, \dots, \alpha'_{r-1})$ is by Lemma 41.19.2 rationally equivalent to a k -cycle on $P_Y = \mathbf{P}(\mathcal{E}|_Y)$ where $Y = X \setminus U$ as a reduced closed subscheme. Note that $\dim_\delta(Y) < \dim_\delta(X)$. By induction the result holds for $P_Y \rightarrow Y$ and hence the result holds for α . Hence we may replace X by any nonempty open of X .

In particular we may assume that $\mathcal{E} \cong \mathcal{O}_X^{\oplus r}$. In this case $\mathbf{P}(\mathcal{E}) = X \times \mathbf{P}^{r-1}$. Let us use the stratification

$$\mathbf{P}^{r-1} = \mathbf{A}^{r-1} \coprod \mathbf{A}^{r-2} \coprod \dots \coprod \mathbf{A}^0$$

The closure of each stratum is a \mathbf{P}^{r-1-i} which is a representative of $c_1(\mathcal{O}(1))^i \cap [\mathbf{P}^{r-1}]$. Hence P has a similar stratification

$$P = U^{r-1} \coprod U^{r-2} \coprod \dots \coprod U^0$$

Let P^i be the closure of U^i . Let $\pi^i : P^i \rightarrow X$ be the restriction of π to P^i . Let $\alpha \in A_{k+r-1}(P)$. By Lemma 41.32.1 we can write $\alpha|_{U^{r-1}} = \pi^*\alpha_0|_{U^{r-1}}$ for some $\alpha_0 \in A_k(X)$. Hence the difference $\alpha - \pi^*\alpha_0$ is the image of some $\alpha' \in A_{k+r-1}(P^{r-2})$. By Lemma 41.32.1 again we can write $\alpha'|_{U^{r-2}} = (\pi^{r-2})^*\alpha_1|_{U^{r-2}}$ for some $\alpha_1 \in A_{k+1}(X)$. By Lemma 41.31.2 we see that the image of $(\pi^{r-2})^*\alpha_1$ represents $c_1(\mathcal{O}_P(1)) \cap \pi^*\alpha_1$. We also see that $\alpha - \pi^*\alpha_0 - c_1(\mathcal{O}_P(1)) \cap \pi^*\alpha_1$ is the image of some $\alpha'' \in A_{k+r-1}(P^{r-3})$. And so on. \square

Lemma 41.33.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on X . Let*

$$p : E = \underline{\text{Spec}}(\text{Sym}^*(\mathcal{E})) \longrightarrow X$$

be the associated vector bundle over X . Then $p^ : A_k(X) \rightarrow A_{k+r}(E)$ is an isomorphism for all k .*

Proof. For surjectivity see Lemma 41.32.1. Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ be the projective space bundle associated to the finite locally free sheaf $\mathcal{E} \oplus \mathcal{O}_X$. Let $s \in \Gamma(P, \mathcal{O}_P(1))$ correspond to the global section $(0, 1) \in \Gamma(X, \mathcal{E} \oplus \mathcal{O}_X)$. Let $D = Z(s) \subset P$. Note that $(\pi|_D : D \rightarrow X, \mathcal{O}_P(1)|_D)$ is the projective space bundle associated to \mathcal{E} . We denote $\pi_D = \pi|_D$ and $\mathcal{O}_D(1) = \mathcal{O}_P(1)|_D$. Moreover, D is an effective Cartier divisor on P . Hence $\mathcal{O}_P(D) = \mathcal{O}_P(1)$ (see Divisors, Lemma 30.9.20). Also there is an isomorphism $E \cong P \setminus D$. Denote $j : E \rightarrow P$ the corresponding open immersion. For injectivity we use that the kernel of

$$j^* : A_{k+r}(P) \longrightarrow A_{k+r}(E)$$

are the cycles supported in the effective Cartier divisor D , see Lemma 41.19.2. So if $p^*\alpha = 0$, then $\pi^*\alpha = i_*\beta$ for some $\beta \in A_{k+r}(D)$. By Lemma 41.33.2 we may write

$$\beta = \pi_D^*\beta_0 + \dots + c_1(\mathcal{O}_D(1))^{r-1} \cap \pi_D^*\beta_{r-1}.$$

for some $\beta_i \in A_{k+i}(X)$. By Lemmas 41.31.2 and 41.25.6 this implies

$$\pi^*\alpha = i_*\beta = c_1(\mathcal{O}_P(1)) \cap \pi^*\beta_0 + \dots + c_1(\mathcal{O}_D(1))^r \cap \pi^*\beta_{r-1}.$$

Since the rank of $\mathcal{E} \oplus \mathcal{O}_X$ is $r+1$ this contradicts Lemma 41.25.6 unless all α and all β_i are zero. \square

41.34. The Chern classes of a vector bundle

We can use the projective space bundle formula to define the chern classes of a rank r vector bundle in terms of the expansion of $c_1(\mathcal{O}(1))^r$ in terms of the lower powers, see formula (41.34.1.1). The reason for the signs will be explained later.

Definition 41.34.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let \mathcal{E} be a finite locally free sheaf of rank r on X . Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ be the projective space bundle associated to \mathcal{E} .

- (1) By Lemma 41.33.2 there are elements $c_i \in A_{n-i}(X)$, $i = 0, \dots, r$ such that $c_0 = [X]$, and

$$(41.34.1.1) \quad \sum_{i=0}^r (-1)^i c_1(\mathcal{O}_P(1))^i \cap \pi^*c_{r-i} = 0.$$

- (2) With notation as above we set $c_i(\mathcal{E}) \cap [X] = c_i$ as an element of $A_{n-i}(X)$. We call these the *chern classes of \mathcal{E} on X* .
 (3) The *total chern class of \mathcal{E} on X* is the combination

$$c(\mathcal{E}) \cap [X] = c_0(\mathcal{E}) \cap [X] + c_1(\mathcal{E}) \cap [X] + \dots + c_r(\mathcal{E}) \cap [X]$$

which is an element of $A_*(X) = \bigoplus_{k \in \mathbf{Z}} A_k(X)$.

Let us check that this does not give a new notion in case the vector bundle has rank 1.

Lemma 41.34.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Assume X is integral and $n = \dim_\delta(X)$. Let \mathcal{L} be an invertible \mathcal{O}_X -module. The first chern class of \mathcal{L} on X of Definition 41.34.1 is equal to the Weil divisor associated to \mathcal{L} by Definition 41.24.1.*

Proof. In this proof we use $c_1(\mathcal{L}) \cap [X]$ to denote the construction of Definition 41.24.1. Since \mathcal{L} has rank 1 we have $\mathbf{P}(\mathcal{L}) = X$ and $\mathcal{O}_{\mathbf{P}(\mathcal{L})}(1) = \mathcal{L}$ by our normalizations. Hence (41.34.1.1) reads

$$(-1)^1 c_1(\mathcal{L}) \cap c_0 + (-1)^0 c_1 = 0$$

Since $c_0 = [X]$, we conclude $c_1 = c_1(\mathcal{L}) \cap [X]$ as desired. □

Remark 41.34.3. We could also rewrite equation 41.34.1.1 as

$$(41.34.3.1) \quad \sum_{i=0}^r c_1(\mathcal{O}_P(-1))^i \cap \pi^* c_{r-i} = 0.$$

but we find it easier to work with the tautological quotient sheaf $\mathcal{O}_P(1)$ instead of its dual.

41.35. Intersecting with chern classes

Definition 41.35.1. Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on X . We define, for every integer k and any $0 \leq j \leq r$, an operation

$$c_j(\mathcal{E}) \cap - : Z_k(X) \rightarrow A_{k-j}(X)$$

called *intersection with the j th chern class of \mathcal{E}* .

- (1) Given an integral closed subscheme $i : W \rightarrow X$ of δ -dimension k we define

$$c_j(\mathcal{E}) \cap [W] = i_*(c_j(i^*\mathcal{E}) \cap [W]) \in A_{k-j}(X)$$

where $c_j(i^*\mathcal{E}) \cap [W]$ is as defined in Definition 41.34.1.

- (2) For a general k -cycle $\alpha = \sum n_i [W_i]$ we set

$$c_j(\mathcal{E}) \cap \alpha = \sum n_i c_j(\mathcal{E}) \cap [W_i]$$

Again, if \mathcal{E} has rank 1 then this agrees with our previous definition.

Lemma 41.35.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on X . Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ be the projective bundle associated to \mathcal{E} . For $\alpha \in Z_k(X)$ the elements $c_j(\mathcal{E}) \cap \alpha$ are the unique elements α_j of $A_{k-j}(X)$ such that $\alpha_0 = \alpha$ and*

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_P(1))^i \cap \pi^*(\alpha_{r-i}) = 0$$

holds in the Chow group of P .

Proof. The uniqueness of $\alpha_0, \dots, \alpha_r$ such that $\alpha_0 = \alpha$ and such that the displayed equation holds follows from the projective space bundle formula Lemma 41.33.2. The identity holds by definition for $\alpha = [X]$. For a general k -cycle α on X write $\alpha = \sum n_a [W_a]$ with $n_a \neq 0$, and $i_a : W_a \rightarrow X$ pairwise distinct integral closed subschemes. Then the family $\{W_a\}$ is locally finite on X . Set $P_a = \pi^{-1}(W_a) = \mathbf{P}(\mathcal{E}|_{W_a})$. Denote $i'_a : P_a \rightarrow P$ the corresponding closed immersions. Consider the fibre product diagram

$$\begin{array}{ccccc} P' & \xlongequal{\quad} & \coprod P_a & \xrightarrow{\quad} & P \\ \pi' \downarrow & & \pi_a \downarrow & & \downarrow \pi \\ X' & \xlongequal{\quad} & \coprod W_a & \xrightarrow{\quad} & X \end{array}$$

The morphism $p : X' \rightarrow X$ is proper. Moreover $\pi' : P' \rightarrow X'$ together with the invertible sheaf $\mathcal{O}_{P'}(1) = \coprod \mathcal{O}_{P_a}(1)$ which is also the pullback of $\mathcal{O}_P(1)$ is the projective bundle associated to $\mathcal{E}' = p^*\mathcal{E}$. By definition

$$c_j(\mathcal{E}) \cap [\alpha] = \sum i_{a,*}(c_j(\mathcal{E}|_{W_a}) \cap [W_a]).$$

Write $\beta_{a,j} = c_j(\mathcal{E}|_{W_a}) \cap [W_a]$ which is an element of $A_{k-j}(W_a)$. We have

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_{P_a}(1))^i \cap \pi_a^*(\beta_{a,r-i}) = 0$$

for each a by definition. Thus clearly we have

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_{P'}(1))^i \cap (\pi')^*(\beta_{r-i}) = 0$$

with $\beta_j = \sum n_a \beta_{a,j} \in A_{k-j}(X')$. Denote $p' : P' \rightarrow P$ the morphism $\coprod i'_a$. We have $\pi^* p_* \beta_j = p'^*(\pi')^* \beta_j$ by Lemma 41.15.1. By the projection formula of Lemma 41.25.6 we conclude that

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_P(1))^i \cap \pi^*(p_* \beta_j) = 0$$

Since $p_* \beta_j$ is a representative of $c_j(\mathcal{E}) \cap \alpha$ we win. □

This characterization of chern classes allows us to prove many more properties.

Lemma 41.35.3. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on X . If $\alpha \sim_{rat} \beta$ are rationally equivalent k -cycles on X then $c_j(\mathcal{E}) \cap \alpha = c_j(\mathcal{E}) \cap \beta$ in $A_{k-j}(X)$.*

Proof. By Lemma 41.35.2 the elements $\alpha_j = c_j(\mathcal{E}) \cap \alpha$, $j \geq 1$ and $\beta_j = c_j(\mathcal{E}) \cap \beta$, $j \geq 1$ are uniquely determined by the *same* equation in the chow group of the projective bundle associated to \mathcal{E} . (This of course relies on the fact that flat pullback is compatible with rational equivalence, see Lemma 41.20.1.) Hence they are equal. □

In other words capping with chern classes of finite locally free sheaves factors through rational equivalence to give maps

$$c_j(\mathcal{E}) \cap - : A_k(X) \rightarrow A_{k-j}(X).$$

Lemma 41.35.4. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on Y . Let $f : X \rightarrow Y$ be a flat morphism of relative dimension r . Let α be a k -cycle on Y . Then*

$$f^*(c_j(\mathcal{E}) \cap \alpha) = c_j(f^*\mathcal{E}) \cap f^*\alpha$$

Proof. Write $\alpha_j = c_j(\mathcal{E}) \cap \alpha$, so $\alpha_0 = \alpha$. By Lemma 41.35.2 we have

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_P(1))^i \cap \pi^*(\alpha_{r-i}) = 0$$

in the chow group of the projective bundle $(\pi : P \rightarrow Y, \mathcal{O}_P(1))$ associated to \mathcal{E} . Consider the fibre product diagram

$$\begin{array}{ccc} P_X = \mathbf{P}(f^*\mathcal{E}) & \xrightarrow{f_P} & P \\ \pi_X \downarrow & & \downarrow \pi \\ X & \xrightarrow{f} & Y \end{array}$$

Note that $\mathcal{O}_{P_X}(1) = f_P^* \mathcal{O}_P(1)$. By Lemmas 41.25.4 and 41.14.3 we see that

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_{P_X}(1))^i \cap \pi_X^*(f^* \alpha_{r-i}) = 0$$

holds in the chow group of P_X . Since $f^* \alpha_0 = f^* \alpha$ the lemma follows from the uniqueness in Lemma 41.35.2. \square

Lemma 41.35.5. *Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on X . Let $p : X \rightarrow Y$ be a proper morphism. Let α be a k -cycle on X . Let \mathcal{E} be a finite locally free sheaf on Y . Then*

$$p_*(c_j(p^* \mathcal{E}) \cap \alpha) = c_j(\mathcal{E}) \cap p_* \alpha$$

Proof. Write $\alpha_j = c_j(p^* \mathcal{E}) \cap \alpha$, so $\alpha_0 = \alpha$. By Lemma 41.35.2 we have

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_P(1))^i \cap \pi_X^*(\alpha_{r-i}) = 0$$

in the chow group of the projective bundle $(\pi_X : P_X \rightarrow X, \mathcal{O}_{P_X}(1))$ associated to $p^* \mathcal{E}$. Let $(\pi : P \rightarrow Y, \mathcal{O}_P(1))$ be the projective bundle associated to \mathcal{E} . Consider the fibre product diagram

$$\begin{array}{ccc} P_X = \mathbf{P}(p^* \mathcal{E}) & \xrightarrow{p_P} & P \\ \pi_X \downarrow & & \downarrow \pi \\ X & \xrightarrow{p} & Y \end{array}$$

Note that $\mathcal{O}_{P_X}(1) = p_P^* \mathcal{O}_P(1)$. Pushing the displayed equality above to P and using Lemmas 41.15.1, 41.25.6 and 41.14.3 we see that

$$\sum_{i=0}^r (-1)^i c_1(\mathcal{O}_P(1))^i \cap \pi^*(p_* \alpha_{r-i}) = 0$$

holds in the chow group of P . Since $p_* \alpha_0 = p_* \alpha$ the lemma follows from the uniqueness in Lemma 41.35.2. \square

Lemma 41.35.6. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E}, \mathcal{F} be finite locally free sheaves on X of ranks r and s . For any $\alpha \in A_k(X)$ we have*

$$c_i(\mathcal{E}) \cap c_j(\mathcal{F}) \cap \alpha = c_j(\mathcal{F}) \cap c_i(\mathcal{E}) \cap \alpha$$

as elements of $A_{k-i-j}(X)$.

Proof. Consider

$$\pi : \mathbf{P}(\mathcal{E}) \times_X \mathbf{P}(\mathcal{F}) \longrightarrow X$$

with invertible sheaves $\mathcal{L} = \text{pr}_1^* \mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)$ and $\mathcal{N} = \text{pr}_2^* \mathcal{O}_{\mathbf{P}(\mathcal{F})}(1)$. Write $\alpha_{i,j}$ for the left hand side and $\beta_{i,j}$ for the right hand side. Also write $\alpha_j = c_j(\mathcal{F}) \cap \alpha$ and $\beta_i = c_i(\mathcal{E}) \cap \alpha$. In particular this means that $\alpha_0 = \alpha = \beta_0$, and $\alpha_{0,j} = \alpha_j = \beta_{0,j}$, $\alpha_{i,0} = \beta_i = \beta_{i,0}$. From Lemma 41.35.2 (pulled back to the space above using

Lemma 41.25.4 for the first two) we see that

$$\begin{aligned} 0 &= \sum_{j=0, \dots, s} (-1)^j c_1(\mathcal{N})^j \cap \pi^* \alpha_{s-j} \\ 0 &= \sum_{i=0, \dots, r} (-1)^i c_1(\mathcal{L})^i \cap \pi^* \beta_{r-i} \\ 0 &= \sum_{i=0, \dots, r} (-1)^i c_1(\mathcal{L})^i \cap \pi^* \alpha_{r-i, s-j} \\ 0 &= \sum_{j=0, \dots, s} (-1)^j c_1(\mathcal{N})^j \cap \pi^* \beta_{r-i, s-j} \end{aligned}$$

We can combine the first and the third of these to get

$$\begin{aligned} &(-1)^{r+s} c_1(\mathcal{L})^r \cap c_1(\mathcal{N})^s \cap \pi^* \alpha \\ &= \sum_{j=1, \dots, s} (-1)^{r+j-1} c_1(\mathcal{L})^r \cap c_1(\mathcal{N})^j \cap \pi^* \alpha_{s-j} \\ &= \sum_{j=1, \dots, s} (-1)^{j-1+r} c_1(\mathcal{N})^j \cap c_1(\mathcal{L})^r \cap \pi^* \alpha_{0, s-j} \\ &= \sum_{j=1}^s \sum_{i=1}^r (-1)^{i+j} c_1(\mathcal{N})^j \cap c_1(\mathcal{L})^i \cap \pi^* \alpha_{r-i, s-j} \end{aligned}$$

using that capping with $c_1(\mathcal{L})$ commutes with capping with $c_1(\mathcal{N})$. In exactly the same way one shows that

$$(-1)^{r+s} c_1(\mathcal{L})^r \cap c_1(\mathcal{N})^s \cap \pi^* \alpha = \sum_{j=1}^s \sum_{i=1}^r (-1)^{i+j} c_1(\mathcal{N})^j \cap c_1(\mathcal{L})^i \cap \pi^* \beta_{r-i, s-j}$$

By the projective space bundle formula Lemma 41.33.2 applied twice these representations are unique. Whence the result. \square

41.36. Polynomial relations among chern classes

Definition 41.36.1. Let $P(x_{i,j}) \in \mathbf{Z}[x_{i,j}]$ be a polynomial. We write P as a finite sum

$$\sum_s \sum_{I=((i_1, j_1), (i_2, j_2), \dots, (i_s, j_s))} a_I x_{i_1, j_1} \cdots x_{i_s, j_s}.$$

Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E}_i be a finite collection of finite locally free sheaves on X . We say that P is a *polynomial relation among the chern classes* and we write $P(c_j(\mathcal{E}_i)) = 0$ if for any morphism $f : Y \rightarrow X$ of an integral scheme locally of finite type over S the cycle

$$\sum_s \sum_{I=((i_1, j_1), (i_2, j_2), \dots, (i_s, j_s))} a_I c_{j_1}(f^* \mathcal{E}_{i_1}) \cap \cdots \cap c_{j_s}(f^* \mathcal{E}_{i_s}) \cap [Y]$$

is zero in $A_*(Y)$.

This is not an elegant definition but it will do for now. It makes sense because we showed in Lemma 41.35.6 that capping with chern classes of vector bundles is commutative. By our definitions and results above this is equivalent with requiring all the operations

$$\sum_s \sum_I a_I c_{j_1}(f^* \mathcal{E}_{i_1}) \cap \cdots \cap c_{j_s}(f^* \mathcal{E}_{i_s}) \cap - : A_*(Y) \rightarrow A_*(Y)$$

to be zero for all morphisms $f : Y \rightarrow X$ which are locally of finite type.

An example of such a relation is the relation

$$c_1(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{N}) = c_1(\mathcal{L}) + c_1(\mathcal{N})$$

proved in Lemma 41.25.2. More generally, here is what happens when we tensor an arbitrary locally free sheaf by an invertible sheaf.

Lemma 41.36.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf of rank r on X . Let \mathcal{L} be an invertible sheaf on X . Then*

$$(41.36.2.1) \quad c_i(\mathcal{E} \otimes \mathcal{L}) = \sum_{j=0}^i \binom{r-i+j}{j} c_{i-j}(\mathcal{E}) c_1(\mathcal{L})^j$$

is a valid polynomial relation in the sense described above.

Proof. This should hold for any triple $(X, \mathcal{E}, \mathcal{L})$. In particular it should hold when X is integral, and in fact by definition of a polynomial relation it is enough to prove it holds when capping with $[X]$ for such X . Thus assume that X is integral. Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$, resp. $(\pi' : P' \rightarrow X, \mathcal{O}_{P'}(1))$ be the projective space bundle associated to \mathcal{E} , resp. $\mathcal{E} \otimes \mathcal{L}$. Consider the canonical morphism

see Constructions, Lemma 26.20.1. It has the property that $g^* \mathcal{O}_{P'}(1) = \mathcal{O}_P(1) \otimes \pi^* \mathcal{L}$. This means that we have

$$\sum_{i=0}^r (-1)^i (\xi + x)^i \cap \pi^*(c_{r-i}(\mathcal{E} \otimes \mathcal{L}) \cap [X]) = 0$$

in $A_*(P)$, where ξ represents $c_1(\mathcal{O}_P(1))$ and x represents $c_1(\pi^* \mathcal{L})$. By simple algebra this is equivalent to

$$\sum_{i=0}^r (-1)^i \xi^i \left(\sum_{j=i}^r (-1)^{j-i} \binom{j}{i} x^{j-i} \cap \pi^*(c_{r-j}(\mathcal{E} \otimes \mathcal{L}) \cap [X]) \right) = 0$$

Comparing with Equation (41.34.1.1) it follows from this that

$$c_{r-i}(\mathcal{E}) \cap [X] = \sum_{j=i}^r \binom{j}{i} (-c_1(\mathcal{L}))^{j-i} \cap c_{r-j}(\mathcal{E} \otimes \mathcal{L}) \cap [X]$$

Reworking this (getting rid of minus signs, and renumbering) we get the desired relation. \square

Some example cases of (41.36.2.1) are

$$\begin{aligned} c_1(\mathcal{E} \otimes \mathcal{L}) &= c_1(\mathcal{E}) + r c_1(\mathcal{L}) \\ c_2(\mathcal{E} \otimes \mathcal{L}) &= c_2(\mathcal{E}) + (r-1) c_1(\mathcal{E}) c_1(\mathcal{L}) + \binom{r}{2} c_1(\mathcal{L})^2 \\ c_3(\mathcal{E} \otimes \mathcal{L}) &= c_3(\mathcal{E}) + (r-2) c_2(\mathcal{E}) c_1(\mathcal{L}) + \binom{r-1}{2} c_1(\mathcal{E}) c_1(\mathcal{L})^2 + \binom{r}{3} c_1(\mathcal{L})^3 \end{aligned}$$

41.37. Additivity of chern classes

All of the preliminary lemmas follow trivially from the final result.

Lemma 41.37.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E}, \mathcal{F} be finite locally free sheaves on X of ranks $r, r-1$ which fit into a short exact sequence*

$$0 \rightarrow \mathcal{O}_X \rightarrow \mathcal{E} \rightarrow \mathcal{F} \rightarrow 0$$

Then

$$c_r(\mathcal{E}) = 0, \quad c_j(\mathcal{E}) = c_j(\mathcal{F}), \quad j = 0, \dots, r - 1$$

are valid polynomial relations among chern classes.

Proof. By Definition 41.36.1 it suffices to show that if X is integral then $c_j(\mathcal{E}) \cap [X] = c_j(\mathcal{F}) \cap [X]$. Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$, resp. $(\pi' : P' \rightarrow X, \mathcal{O}_{P'}(1))$ denote the projective space bundle associated to \mathcal{E} , resp. \mathcal{F} . The surjection $\mathcal{E} \rightarrow \mathcal{F}$ gives rise to a closed immersion

$$i : P' \longrightarrow P$$

over X . Moreover, the element $1 \in \Gamma(X, \mathcal{O}_X) \subset \Gamma(X, \mathcal{E})$ gives rise to a global section $s \in \Gamma(P, \mathcal{O}_P(1))$ whose zero set is exactly P' . Hence P' is an effective Cartier divisor on P such that $\mathcal{O}_P(P') \cong \mathcal{O}_P(1)$. Hence we see that

$$c_1(\mathcal{O}_P(1)) \cap \pi^* \alpha = i_*((\pi')^* \alpha)$$

for any cycle class α on X by Lemma 41.31.2. By Lemma 41.35.2 we see that $\alpha_j = c_j(\mathcal{F}) \cap [X]$, $j = 0, \dots, r - 1$ satisfy

$$\sum_{j=0}^{r-1} (-1)^j c_1(\mathcal{O}_{P'}(1))^j \cap (\pi')^* \alpha_j = 0$$

Pushing this to P and using the remark above as well as Lemma 41.25.6 we get

$$\sum_{j=0}^{r-1} (-1)^j c_1(\mathcal{O}_P(1))^{j+1} \cap \pi^* \alpha_j = 0$$

By the uniqueness of Lemma 41.35.2 we conclude that $c_r(\mathcal{E}) \cap [X] = 0$ and $c_j(\mathcal{E}) \cap [X] = \alpha_j = c_j(\mathcal{F}) \cap [X]$ for $j = 0, \dots, r - 1$. Hence the lemma holds. \square

Lemma 41.37.2. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E}, \mathcal{F} be finite locally free sheaves on X of ranks $r, r - 1$ which fit into a short exact sequence*

$$0 \rightarrow \mathcal{L} \rightarrow \mathcal{E} \rightarrow \mathcal{F} \rightarrow 0$$

where \mathcal{L} is an invertible sheaf Then

$$c(\mathcal{E}) = c(\mathcal{L})c(\mathcal{F})$$

is a valid polynomial relation among chern classes.

Proof. This relation really just says that $c_i(\mathcal{E}) = c_i(\mathcal{F}) + c_1(\mathcal{L})c_{i-1}(\mathcal{F})$. By Lemma 41.37.1 we have $c_j(\mathcal{E} \otimes \mathcal{L}^{\otimes -1}) = c_j(\mathcal{E} \otimes \mathcal{L}^{\otimes -1})$ for $j = 0, \dots, r$ (were we set $c_r(\mathcal{F}) = 0$ by convention). Applying Lemma 41.36.2 we deduce

$$\sum_{j=0}^i \binom{r-i+j}{j} (-1)^j c_{i-j}(\mathcal{E}) c_1(\mathcal{L})^j = \sum_{j=0}^i \binom{r-1-i+j}{j} (-1)^j c_{i-j}(\mathcal{F}) c_1(\mathcal{L})^j$$

Setting $c_i(\mathcal{E}) = c_i(\mathcal{F}) + c_1(\mathcal{L})c_{i-1}(\mathcal{F})$ gives a “solution” of this equation. The lemma follows if we show that this is the only possible solution. We omit the verification. \square

Lemma 41.37.3. *Let (S, δ) be as in Situation 41.7.1. Let X be a scheme locally of finite type over S . Suppose that \mathcal{E} sits in an exact sequence*

$$0 \rightarrow \mathcal{E}_1 \rightarrow \mathcal{E} \rightarrow \mathcal{E}_2 \rightarrow 0$$

of finite locally free sheaves \mathcal{E}_i of rank r_i . Then

$$c(\mathcal{E}) = c(\mathcal{E}_1)c(\mathcal{E}_2)$$

is a polynomial relation among chern classes.

Proof. We may assume that X is integral and we have to show the identity when capping against $[X]$. By induction on r_1 . The case $r_1 = 1$ is Lemma 41.37.2. Assume $r_1 > 1$. Let $(\pi : P \rightarrow X, \mathcal{O}_P(1))$ denote the projective space bundle associated to \mathcal{E}_1 . Note that

- (1) $\pi^* : A_*(X) \rightarrow A_*(P)$ is injective, and
- (2) $\pi^*\mathcal{E}_1$ sits in a short exact sequence $0 \rightarrow \mathcal{F} \rightarrow \pi^*\mathcal{E}_1 \rightarrow \mathcal{L} \rightarrow 0$ where \mathcal{L} is invertible.

The first assertion follows from the projective space bundle formula and the second follows from the definition of a projective space bundle. (In fact $\mathcal{L} = \mathcal{O}_P(1)$.) Let $Q = \pi^*\mathcal{E}/\mathcal{F}$, which sits in an exact sequence $0 \rightarrow \mathcal{L} \rightarrow Q \rightarrow \pi^*\mathcal{E}_2 \rightarrow 0$. By induction we have

$$\begin{aligned} c(\pi^*\mathcal{E}) \cap [P] &= c(\mathcal{F}) \cap c(\pi^*\mathcal{E}/\mathcal{F}) \cap [P] \\ &= c(\mathcal{F}) \cap c(\mathcal{L}) \cap c(\pi^*\mathcal{E}_2) \cap [P] \\ &= c(\pi^*\mathcal{E}_1) \cap c(\pi^*\mathcal{E}_2) \cap [P] \end{aligned}$$

Since $[P] = \pi^*[X]$ we win by Lemma 41.35.4. \square

Lemma 41.37.4. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{L}_i , $i = 1, \dots, r$ be invertible \mathcal{O}_X -modules on X . Let \mathcal{E} be a finite locally free rank r \mathcal{O}_X -module endowed with a filtration*

$$0 = \mathcal{E}_0 \subset \mathcal{E}_1 \subset \mathcal{E}_2 \subset \dots \subset \mathcal{E}_r = \mathcal{E}$$

such that $\mathcal{E}_i/\mathcal{E}_{i-1} \cong \mathcal{L}_i$. Set $c_1(\mathcal{L}_i) = x_i$. Then

$$c(\mathcal{E}) = \prod_{i=1}^r (1 + x_i)$$

is a valid polynomial relation among chern classes in the sense of Definition 41.36.1.

Proof. Apply Lemma 41.37.2 and induction. \square

41.38. The splitting principle

In our setting it is not so easy to say what the splitting principle exactly says/is. Here is a possible formulation.

Lemma 41.38.1. *Let (S, δ) be as in Situation 41.7.1. Let X be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf \mathcal{E} on X of rank r . There exists a projective flat morphism of relative dimension d $\pi : P \rightarrow X$ such that*

- (1) for any morphism $f : Y \rightarrow X$ the map $\pi_Y^* : A_*(Y) \rightarrow A_{*+r}(Y \times_X P)$ is injective, and
- (2) $\pi^*\mathcal{E}$ has a filtration with successive quotients $\mathcal{L}_1, \dots, \mathcal{L}_r$ for some invertible \mathcal{O}_P -modules \mathcal{L}_i .

Proof. Omitted. Hint: Use a composition of projective space bundles, i.e., a flag variety over X . \square

The splitting principle refers to the practice of symbolically writing

$$c(\mathcal{E}) = \prod (1 + x_i)$$

with $x_i = c_1(\mathcal{L}_i)$. The expressions x_i are then called the *Chern roots* of \mathcal{E} . In order to prove polynomial relations among chern classes of vector bundles it is permissible to do calculations using the chern roots.

For example, let us calculate the chern classes of the dual vector bundle \mathcal{E}^\wedge . Note that if \mathcal{E} has a filtration with subquotients invertible sheaves \mathcal{L}_i then \mathcal{E}^\wedge has a filtration with subquotients the invertible sheaves \mathcal{L}_i^{-1} . Hence if x_i are the chern roots of \mathcal{E} , then the $-x_i$ are the chern roots of \mathcal{E}^\wedge . It follows that

$$c_j(\mathcal{E}^\wedge) = (-1)^j c_j(\mathcal{E})$$

is a valid polynomial relation among chern classes.

In the same vain, let us compute the chern classes of a tensor product of vector bundles. Namely, suppose that \mathcal{E}, \mathcal{F} are finite locally free of ranks r, s . Write

$$c(\mathcal{E}) = \prod_{i=1}^r (1 + x_i), \quad c(\mathcal{F}) = \prod_{j=1}^s (1 + y_j)$$

where x_i, y_j are the chern roots of \mathcal{E}, \mathcal{F} . Then we see that

$$c(\mathcal{E} \otimes_{\mathcal{O}_X} \mathcal{F}) = \prod_{i,j} (1 + x_i + y_j)$$

Here are some examples of what this means in terms of chern classes

$$\begin{aligned} c_1(\mathcal{E} \otimes \mathcal{F}) &= r c_1(\mathcal{F}) + s c_1(\mathcal{E}) \\ c_2(\mathcal{E} \otimes \mathcal{F}) &= r^2 c_2(\mathcal{F}) + r s c_1(\mathcal{F}) c_1(\mathcal{E}) + s^2 c_2(\mathcal{E}) \end{aligned}$$

41.39. Chern classes and tensor product

We define the *Chern character* of a finite locally free sheaf of rank r to be the formal expression

$$ch(\mathcal{E}) := \sum_{i=1}^r e^{x_i}$$

if the x_i are the chern roots of \mathcal{E} . Writing this in terms of chern classes $c_i = c_i(\mathcal{E})$ we see that

$$ch(\mathcal{E}) = r + c_1 + \frac{1}{2}(c_1^2 - 2c_2) + \frac{1}{6}(c_1^3 - 3c_1 c_2 + 3c_3) + \frac{1}{24}(c_1^4 - 4c_1^2 c_2 + 4c_1 c_3 + 2c_2^2 - 4c_4) + \dots$$

What does it mean that the coefficients are rational numbers? Well this simply means that we think of these as operations

$$ch_j(\mathcal{E}) \cap - : A_k(X) \longrightarrow A_{k-j}(X) \otimes_{\mathbf{Z}} \mathbf{Q}$$

and we think of polynomial relations among them as relations between these operations with values in the groups $A_{k-j}(Y) \otimes_{\mathbf{Z}} \mathbf{Q}$ for varying Y . By the above we have in case of an exact sequence

$$0 \rightarrow \mathcal{E}_1 \rightarrow \mathcal{E} \rightarrow \mathcal{E}_2 \rightarrow 0$$

that

$$ch(\mathcal{E}) = ch(\mathcal{E}_1) + ch(\mathcal{E}_2)$$

Using the Chern character we can express the compatibility of the chern classes and tensor product as follows:

$$ch(\mathcal{E}_1 \otimes_{\mathcal{O}_X} \mathcal{E}_2) = ch(\mathcal{E}_1) ch(\mathcal{E}_2)$$

This follows directly from the discussion of the chern roots of the tensor product in the previous section.

41.40. Todd classes

A final class associated to a vector bundle \mathcal{E} of rank r is its *Todd class* $Todd(\mathcal{E})$. In terms of the chern roots x_1, \dots, x_r it is defined as

$$Todd(\mathcal{E}) = \prod_{i=1}^r \frac{x_i}{1 - e^{-x_i}}$$

In terms of the chern classes $c_i = c_i(\mathcal{E})$ we have

$$Todd(\mathcal{E}) = 1 + \frac{1}{2}c_1 + \frac{1}{12}(c_1^2 + c_2) + \frac{1}{24}c_1c_2 + \frac{1}{720}(-c_1^4 + 4c_1^2c_2 + 3c_2^2 + c_1c_3 - c_4) + \dots$$

We have made the appropriate remarks about denominators in the previous section. It is the case that given an exact sequence

$$0 \rightarrow \mathcal{E}_1 \rightarrow \mathcal{E} \rightarrow \mathcal{E}_2 \rightarrow 0$$

we have

$$Todd(\mathcal{E}) = Todd(\mathcal{E}_1)Todd(\mathcal{E}_2).$$

41.41. Grothendieck-Riemann-Roch

Let (S, δ) be as in Situation 41.7.1. Let X, Y be locally of finite type over S . Let \mathcal{E} be a finite locally free sheaf \mathcal{E} on X of rank r . Let $f : X \rightarrow Y$ be a proper smooth morphism. Assume that $R^i f_* \mathcal{E}$ are locally free sheaves on Y of finite rank (for example if Y is a point). The Grothendieck-Riemann-Roch theorem implies that in this case we have

$$f_*(Todd(T_{X/Y})ch(\mathcal{E})) = \sum (-1)^i ch(R^i f_* \mathcal{E})$$

Here

$$T_{X/Y} = \mathcal{H}om_{\mathcal{O}_X}(\Omega_{X/Y}, \mathcal{O}_X)$$

is the relative tangent bundle of X over Y . The theorem is more general and becomes easier to prove when formulated in correct generality. We will return to this elsewhere (insert future reference here).

Adequate Modules

42.1. Introduction

For any scheme X the category $QCoh(\mathcal{O}_X)$ of quasi-coherent modules is abelian and a weak Serre subcategory of the abelian category of all \mathcal{O}_X -modules. The same thing works for the category of quasi-coherent modules on an algebraic space X viewed as a subcategory of the category of all \mathcal{O}_X -modules on the small étale site of X . Moreover, for a quasi-compact and quasi-separated morphism $f : X \rightarrow Y$ the pushforward f_* and higher direct images preserve quasi-coherency.

Next, let X be a scheme and let \mathcal{O} be the structure sheaf on one of the big sites of X , say, the big fppf site. The category of quasi-coherent \mathcal{O} -modules is abelian (in fact it is equivalent to the category of usual quasi-coherent \mathcal{O}_X -modules on the scheme X we mentioned above) but its imbedding into $Mod(\mathcal{O})$ is not exact. An example is the map of quasi-coherent modules

$$\mathcal{O}_{\mathbf{A}_k^1} \longrightarrow \mathcal{O}_{\mathbf{A}_k^1}$$

on $\mathbf{A}_k^1 = \text{Spec}(k[x])$ given by multiplication by x . In the abelian category of quasi-coherent sheaves this map is injective, whereas in the abelian category of all \mathcal{O} -modules on the big site of \mathbf{A}_k^1 this map has a nontrivial kernel as we see by evaluating on sections over $\text{Spec}(k[x]/(x)) = \text{Spec}(k)$. Moreover, for a quasi-compact and quasi-separated morphism $f : X \rightarrow Y$ the functor $f_{big,*}$ does not preserve quasi-coherency.

In this chapter we introduce a larger category of modules, closely related to quasi-coherent modules, which “fixes” the two problems mentioned above.

42.2. Conventions

In this chapter we fix $\tau \in \{Zar, \acute{e}tale, smooth, syntomic, fppf\}$ and we fix a big τ -site Sch_τ as in Topologies, Section 33.2. All schemes will be objects of Sch_τ . In particular, given a scheme S we obtain sites $(Aff/S)_\tau \subset (Sch/S)_\tau$. The structure sheaf \mathcal{O} on these sites is defined by the rule $\mathcal{O}(T) = \Gamma(T, \mathcal{O}_T)$.

All rings A will be such that $\text{Spec}(A)$ is (isomorphic to) an object of Sch_τ . Given a ring A we denote Alg_A the category of A -algebras whose objects are the A -algebras B of the form $B = \Gamma(U, \mathcal{O}_U)$ where S is an affine object of Sch_τ . Thus given an affine scheme $S = \text{Spec}(A)$ the functor

$$(Aff/S)_\tau \longrightarrow Alg_A, \quad U \longmapsto \mathcal{O}(U)$$

is an equivalence.

42.3. Adequate functors

In this section we discuss a topic closely related to direct images of quasi-coherent sheaves. Most of this material was taken from the paper [Jaf97].

Definition 42.3.1. Let A be a ring. A *module-valued functor* is a functor $F : \text{Alg}_A \rightarrow \text{Ab}$ such that

- (1) for every object B of Alg_A the group $F(B)$ is endowed with the structure of a B -module, and
- (2) for any morphism $B \rightarrow B'$ of Alg_A the map $F(B) \rightarrow F(B')$ is B -linear.

A *morphism of module-valued functors* is a transformation of functors $\varphi : F \rightarrow G$ such that $F(B) \rightarrow G(B)$ is B -linear for all $B \in \text{Ob}(\text{Alg}_A)$.

Let $S = \text{Spec}(A)$ be an affine scheme. The category of module-valued functors on Alg_A is equivalent to the category $\text{PMod}((\text{Aff}/S)_\tau, \mathcal{O})$ of presheaves of \mathcal{O} -modules. The equivalence is given by the rule which assigns to the module-valued functor F the presheaf \mathcal{F} defined by the rule $\mathcal{F}(U) = F(\mathcal{O}(U))$. This is clear from the equivalence $(\text{Aff}/S)_\tau \rightarrow \text{Alg}_A$, $U \mapsto \mathcal{O}(U)$ given in Section 42.2. The quasi-inverse sets $F(B) = \mathcal{F}(\text{Spec}(B))$.

An important special case of a module-valued functor comes about as follows. Let M be an A -module. Then we will denote \underline{M} the module-valued functor $B \mapsto M \otimes_A B$ (with obvious B -module structure). Note that if $M \rightarrow N$ is a map of A -modules then there is an associated morphism $\underline{M} \rightarrow \underline{N}$ of module-valued functors. Conversely, any morphism of module-valued functors $\underline{M} \rightarrow \underline{N}$ comes from an A -module map $M \rightarrow N$ as the reader can see by evaluating on $B = A$. In other words Mod_A is a full subcategory of the category of module-valued functors on Alg_A .

Given an A -module map $\varphi : M \rightarrow N$ then $\text{Coker}(\underline{M} \rightarrow \underline{N}) = \underline{Q}$ where $Q = \text{Coker}(M \rightarrow N)$ because \otimes is right exact. But this isn't the case for the kernel in general: for example an injective map of A -modules need not be injective after base change. Thus the following definition makes sense.

Definition 42.3.2. Let A be a ring. A module-valued functor F on Alg_A is called

- (1) *adequate* if there exists a map of A -modules $M \rightarrow N$ such that F is isomorphic to $\text{Ker}(\underline{M} \rightarrow \underline{N})$.
- (2) *linearly adequate* if F is isomorphic to the kernel of a map $\underline{A^{\oplus n}} \rightarrow \underline{A^{\oplus m}}$.

Note that F is adequate if and only if there exists an exact sequence $0 \rightarrow F \rightarrow \underline{M} \rightarrow \underline{N}$ and F is linearly adequate if and only if there exists an exact sequence $0 \rightarrow F \rightarrow \underline{A^{\oplus n}} \rightarrow \underline{A^{\oplus m}}$.

Let A be a ring. In this section we will show the category of adequate functors on Alg_A is abelian (Lemmas 42.3.10 and 42.3.11) and has a set of generators (Lemma 42.3.6). We will also see that it is a weak Serre subcategory of the category of all module-valued functors on Alg_A (Lemma 42.3.16) and that it has arbitrary colimits (Lemma 42.3.12).

Lemma 42.3.3. *Let A be a ring. Let F be an adequate functor on Alg_A . If $B = \text{colim } B_i$ is a filtered colimit of A -algebras, then $F(B) = \text{colim } F(B_i)$.*

Proof. This holds because for any A -module M we have $M \otimes_A B = \text{colim } M \otimes_A B_i$ (see Algebra, Lemma 10.11.9) and because filtered colimits commute with exact sequences, see Algebra, Lemma 10.8.9. \square

Remark 42.3.4. Consider the category $Alg_{fp,A}$ whose objects are A -algebras B of the form $B = A[x_1, \dots, x_n]/(f_1, \dots, f_m)$ and whose morphisms are A -algebra maps. Every A -algebra B is a filtered colimit of finitely presented A -algebra, i.e., a filtered colimit of objects of $Alg_{fp,A}$. By Lemma 42.3.3 we conclude every adequate functor F is determined by its restriction to $Alg_{fp,A}$. For some questions we can therefore restrict to functors on $Alg_{fp,A}$. For example, the category of adequate functors does not depend on the choice of the big τ -site chosen in Section 42.2.

Lemma 42.3.5. *Let A be a ring. Let F be an adequate functor on Alg_A . If $B \rightarrow B'$ is flat, then $F(B) \otimes_B B' \rightarrow F(B')$ is an isomorphism.*

Proof. Choose an exact sequence $0 \rightarrow F \rightarrow \underline{M} \rightarrow \underline{N}$. This gives the diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & F(B) \otimes_B B' & \longrightarrow & (M \otimes_A B) \otimes_B B' & \longrightarrow & (N \otimes_A B) \otimes_B B' \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & F(B') & \longrightarrow & M \otimes_A B' & \longrightarrow & N \otimes_A B' \end{array}$$

where the rows are exact (the top one because $B \rightarrow B'$ is flat). Since the right two vertical arrows are isomorphisms, so is the left one. \square

Lemma 42.3.6. *Let A be a ring. Let F be an adequate functor on Alg_A . Then there exists a surjection $L \rightarrow F$ with L a direct sum of linearly adequate functors.*

Proof. Choose an exact sequence $0 \rightarrow F \rightarrow \underline{M} \rightarrow \underline{N}$ where $\underline{M} \rightarrow \underline{N}$ is given by $\varphi : M \rightarrow N$. By Lemma 42.3.3 it suffices to construct $L \rightarrow F$ such that $L(B) \rightarrow F(B)$ is surjective for every finitely presented A -algebra B . Hence it suffices to construct, given a finitely presented A -algebra B and an element $\xi \in F(B)$ a map $L \rightarrow F$ with L linearly adequate such that ξ is in the image of $L(B) \rightarrow F(B)$. (Because there is a set worth of such pairs (B, ξ) up to isomorphism.)

To do this write $\sum_{i=1, \dots, n} m_i \otimes b_i$ the image of ξ in $\underline{M}(B) = M \otimes_A B$. We know that $\sum \varphi(m_i) \otimes b_i = 0$ in $N \otimes_A B$. As N is a filtered colimit of finitely presented A -modules, we can find a finitely presented A -module N' , a commutative diagram of A -modules

$$\begin{array}{ccc} A^{\oplus n} & \longrightarrow & N' \\ m_1, \dots, m_n \downarrow & & \downarrow \\ M & \longrightarrow & N \end{array}$$

such that (b_1, \dots, b_n) maps to zero in $N' \otimes_A B$. Choose a presentation $A^{\oplus l} \rightarrow A^{\oplus k} \rightarrow N' \rightarrow 0$. Choose a lift $A^{\oplus n} \rightarrow A^{\oplus k}$ of the map $A^{\oplus n} \rightarrow N'$ of the diagram. Then we see that there exist $(c_1, \dots, c_l) \in B^{\oplus l}$ such that $(b_1, \dots, b_n, c_1, \dots, c_l)$ maps to zero in $B^{\oplus k}$ under the map $B^{\oplus n} \oplus B^{\oplus l} \rightarrow B^{\oplus k}$. Consider the commutative diagram

$$\begin{array}{ccc} A^{\oplus n} \oplus A^{\oplus l} & \longrightarrow & A^{\oplus k} \\ \downarrow & & \downarrow \\ M & \longrightarrow & N \end{array}$$

where the left vertical arrow is zero on the summand $A^{\oplus l}$. Then we see that L equal to the kernel of $A^{\oplus n+l} \rightarrow A^{\oplus k}$ works because the element $(b_1, \dots, b_n, c_1, \dots, c_l) \in L(B)$ maps to ξ . \square

Consider a graded A -algebra $B = \bigoplus_{d \geq 0} B_d$. Then there are two A -algebra maps $p, a : B \rightarrow B[t, t^{-1}]$, namely $p : b \mapsto b$ and $a : b \mapsto t^{\deg(b)}b$ where b is homogeneous. If F is a module-valued functor on Alg_A , then we define

$$(42.3.6.1) \quad F(B)^{(k)} = \{\xi \in F(B) \mid t^k F(p)(\xi) = F(a)(\xi)\}.$$

For functors which behave well with respect to flat ring extensions this gives a direct sum decomposition. This amounts to the fact that representations of \mathbf{G}_m are completely reducible.

Lemma 42.3.7. *Let A be a ring. Let F be a module-valued functor on Alg_A . Assume that for $B \rightarrow B'$ flat the map $F(B) \otimes_B B' \rightarrow F(B')$ is an isomorphism. Let B be a graded A -algebra. Then*

- (1) $F(B) = \bigoplus_{k \in \mathbf{Z}} F(B)^{(k)}$, and
- (2) the map $B \rightarrow B_0 \rightarrow B$ induces map $F(B) \rightarrow F(B)$ whose image is contained in $F(B)^{(0)}$.

Proof. Let $x \in F(B)$. The map $p : B \rightarrow B[t, t^{-1}]$ is free hence we know that

$$F(B[t, t^{-1}]) = \bigoplus_{k \in \mathbf{Z}} F(p)(F(B)) \cdot t^k = \bigoplus_{k \in \mathbf{Z}} F(B) \cdot t^k$$

as indicated we drop the $F(p)$ in the rest of the proof. Write $F(a)(x) = \sum t^k x_k$ for some $x_k \in F(B)$. Denote $\epsilon : B[t, t^{-1}] \rightarrow B$ the B -algebra map $t \mapsto 1$. Note that the compositions $\epsilon \circ p, \epsilon \circ a : B \rightarrow B[t, t^{-1}] \rightarrow B$ are the identity. Hence we see that

$$x = F(\epsilon)(F(a)(x)) = F(\epsilon)(\sum t^k x_k) = \sum x_k.$$

On the other hand, we claim that $x_k \in F(B)^{(k)}$. Namely, consider the commutative diagram

$$\begin{array}{ccc} B & \xrightarrow{a} & B[t, t^{-1}] \\ a' \downarrow & & \downarrow f \\ B[s, s^{-1}] & \xrightarrow{g} & B[t, s, t^{-1}, s^{-1}] \end{array}$$

where $a'(b) = s^{\deg(b)}b$, $f(b) = b$, $f(t) = st$ and $g(b) = t^{\deg(b)}b$ and $g(s) = s$. Then

$$F(g)(F(a'))(x) = F(g)(\sum s^k x_k) = \sum s^k F(a)(x_k)$$

and going the other way we see

$$F(f)(F(a))(x) = F(f)(\sum t^k x_k) = \sum (st)^k x_k.$$

Since $B \rightarrow B[s, t, s^{-1}, t^{-1}]$ is free we see that $F(B[t, s, t^{-1}, s^{-1}]) = \bigoplus_{k, l \in \mathbf{Z}} F(B) \cdot t^k s^l$ and comparing coefficients in the expressions above we find $F(a)(x_k) = t^k x_k$ as desired.

Finally, the image of $F(B_0) \rightarrow F(B)$ is contained in $F(B)^{(0)}$ because $B_0 \rightarrow B \xrightarrow{a} B[t, t^{-1}]$ is equal to $B_0 \rightarrow B \xrightarrow{p} B[t, t^{-1}]$. □

As a particular case of Lemma 42.3.7 note that

$$\underline{M}(B)^{(k)} = M \otimes_A B_k$$

where B_k is the degree k part of the graded A -algebra B .

Lemma 42.3.8. *Let A be a ring. Given a solid diagram*

$$\begin{array}{ccccccc}
 0 & \longrightarrow & L & \longrightarrow & A^{\oplus n} & \longrightarrow & A^{\oplus m} \\
 & & \downarrow \varphi & & \swarrow \text{dotted} & & \\
 & & \underline{M} & & & &
 \end{array}$$

of module-valued functors on Alg_A with exact row there exists a dotted arrow making the diagram commute.

Proof. Suppose that the map $A^{\oplus n} \rightarrow A^{\oplus m}$ is given by the $m \times n$ -matrix (a_{ij}) . Consider the ring $B = A[x_1, \dots, x_n]/(\sum a_{ij}x_j)$. The element $(x_1, \dots, x_n) \in A^{\oplus n}(B)$ maps to zero in $A^{\oplus m}(B)$ hence is the image of a unique element $\xi \in L(B)$. Note that ξ has the following universal property: for any A -algebra C and any $\xi' \in L(C)$ there exists an A -algebra map $B \rightarrow C$ such that ξ maps to ξ' via the map $L(B) \rightarrow L(C)$.

Note that B is a graded A -algebra, hence we can use Lemmas 42.3.7 and 42.3.5 to decompose the values of our functors on B into graded pieces. Note that $\xi \in L(B)^{(1)}$ as (x_1, \dots, x_n) is an element of degree one in $A^{\oplus n}(B)$. Hence we see that $\varphi(\xi) \in \underline{M}(B)^{(1)} = M \otimes_A B_1$. Since B_1 is generated by x_1, \dots, x_n as an A -module we can write $\varphi(\xi) = \sum m_i \otimes x_i$. Consider the map $A^{\oplus n} \rightarrow M$ which maps the i th basis vector to m_i . By construction the associated map $A^{\oplus n} \rightarrow \underline{M}$ maps the element ξ to $\varphi(\xi)$. It follows from the universal property mentioned above that the diagram commutes. \square

Lemma 42.3.9. *Let A be a ring. Let $\varphi : F \rightarrow \underline{M}$ be a map of module-valued functors on Alg_A with F adequate. Then $\text{Coker}(\varphi)$ is adequate.*

Proof. By Lemma 42.3.6 we may assume that $F = \bigoplus L_i$ is a direct sum of linearly adequate functors. Choose exact sequences $0 \rightarrow L_i \rightarrow A^{\oplus n_i} \rightarrow A^{\oplus m_i}$. For each i choose a map $A^{\oplus n_i} \rightarrow M$ as in Lemma 42.3.8. Consider the diagram

$$\begin{array}{ccccccc}
 0 & \longrightarrow & \bigoplus L_i & \longrightarrow & \bigoplus A^{\oplus n_i} & \longrightarrow & \bigoplus A^{\oplus m_i} \\
 & & \downarrow & & \swarrow & & \\
 & & \underline{M} & & & &
 \end{array}$$

Consider the A -modules

$$Q = \text{Coker}(\bigoplus A^{\oplus n_i} \rightarrow M \oplus \bigoplus A^{\oplus m_i}) \quad \text{and} \quad P = \text{Coker}(\bigoplus A^{\oplus n_i} \rightarrow \bigoplus A^{\oplus m_i}).$$

Then we see that $\text{Coker}(\varphi)$ is isomorphic to the kernel of $\underline{Q} \rightarrow \underline{P}$. \square

Lemma 42.3.10. *Let A be a ring. Let $\varphi : F \rightarrow G$ be a map of adequate functors on Alg_A . Then $\text{Coker}(\varphi)$ is adequate.*

Proof. Choose an injection $G \rightarrow \underline{M}$. Then we have an injection $G/F \rightarrow \underline{M}/F$. By Lemma 42.3.9 we see that \underline{M}/F is adequate, hence we can find an injection $\underline{M}/F \rightarrow \underline{N}$. Composing we obtain an injection $G/F \rightarrow \underline{N}$. By Lemma 42.3.9 the cokernel of the induced map $G \rightarrow \underline{N}$ is adequate hence we can find an injection $\underline{N}/G \rightarrow \underline{K}$. Then $0 \rightarrow G/F \rightarrow \underline{N} \rightarrow \underline{K}$ is exact and we win. \square

Lemma 42.3.11. *Let A be a ring. Let $\varphi : F \rightarrow G$ be a map of adequate functors on Alg_A . Then $\text{Ker}(\varphi)$ is adequate.*

Proof. Choose an injection $F \rightarrow \underline{M}$ and an injection $G \rightarrow \underline{N}$. Denote $F \rightarrow \underline{M \oplus N}$ the diagonal map so that

$$\begin{array}{ccc} F & \longrightarrow & G \\ \downarrow & & \downarrow \\ \underline{M \oplus N} & \longrightarrow & \underline{N} \end{array}$$

commutes. By Lemma 42.3.10 we can find a module map $\underline{M \oplus N} \rightarrow \underline{K}$ such that F is the kernel of $\underline{M \oplus N} \rightarrow \underline{K}$. Then $\text{Ker}(\varphi)$ is the kernel of $\underline{M \oplus N} \rightarrow \underline{K \oplus N}$. \square

Lemma 42.3.12. *Let A be a ring. An arbitrary direct sum of adequate functors on Alg_A is adequate. A colimit of adequate functors is adequate.*

Proof. The statement on direct sums is immediate. A general colimit can be written as a kernel of a map between direct sums, see Categories, Lemma 4.14.11. Hence this follows from Lemma 42.3.11. \square

Lemma 42.3.13. *Let A be a ring. Let F, G be module-valued functors on Alg_A . Let $\varphi : F \rightarrow G$ be a transformation of functors. Assume*

- (1) φ is additive,
- (2) for every A -algebra B and $\xi \in F(B)$ and unit $u \in B^*$ we have $\varphi(u\xi) = u\varphi(\xi)$ in $G(B)$, and
- (3) for any flat ring map $B \rightarrow B'$ we have $G(B) \otimes_B B' = G(B')$.

Then φ is a morphism of module-valued functors.

Proof. Let B be an A -algebra, $\xi \in F(B)$, and $b \in B$. We have to show that $\varphi(b\xi) = b\varphi(\xi)$. Consider the ring map

$$B \rightarrow B' = B[x, y, x^{-1}, y^{-1}]/(x + y - b).$$

This ring map is faithfully flat, hence $G(B) \subset G(B')$. On the other hand

$$\varphi(b\xi) = \varphi((x + y)\xi) = \varphi(x\xi) + \varphi(y\xi) = x\varphi(\xi) + y\varphi(\xi) = (x + y)\varphi(\xi) = b\varphi(\xi)$$

because x, y are units in B' . Hence we win. \square

Lemma 42.3.14. *Let A be a ring. Let $0 \rightarrow \underline{M} \rightarrow G \rightarrow L \rightarrow 0$ be a short exact sequence of module-valued functors on Alg_A with L linearly adequate. Then G is adequate.*

Proof. We first point out that for any flat A -algebra map $B \rightarrow B'$ the map $G(B) \otimes_B B' \rightarrow G(B')$ is an isomorphism. Namely, this holds for \underline{M} and L , see Lemma 42.3.5 and hence follows for G by the five lemma. In particular, by Lemma 42.3.7 we see that $G(B) = \bigoplus_{k \in \mathbf{Z}} G(B)^{(k)}$ for any graded A -algebra B .

Choose an exact sequence $0 \rightarrow L \rightarrow \underline{A}^{\oplus n} \rightarrow \underline{A}^{\oplus m}$. Suppose that the map $\underline{A}^{\oplus n} \rightarrow \underline{A}^{\oplus m}$ is given by the $m \times n$ -matrix (a_{ij}) . Consider the graded A -algebra $B = A[x_1, \dots, x_n]/(\sum a_{ij}x_j)$. The element $(x_1, \dots, x_n) \in \underline{A}^{\oplus n}(B)$ maps to zero in $\underline{A}^{\oplus m}(B)$ hence is the image of a unique element $\xi \in L(B)$. Observe that $\xi \in L(B)^{(1)}$. The map

$$\text{Hom}_A(B, C) \longrightarrow L(C), \quad f \longmapsto L(f)(\xi)$$

defines an isomorphism of functors. The reason is that f is determined by the images $c_i = f(x_i) \in C$ which have to satisfy the relations $\sum a_{ij}c_j = 0$. And $L(C)$ is the set of n -tuples (c_1, \dots, c_n) satisfying the relations $\sum a_{ij}c_j = 0$.

Since the value of each of the functors \underline{M} , G , L on B is a direct sum of its weight spaces (by the lemma mentioned above) exactness of $0 \rightarrow \underline{M} \rightarrow G \rightarrow L \rightarrow 0$ implies the sequence $0 \rightarrow \underline{M}(B)^{(1)} \rightarrow G(B)^{(1)} \rightarrow L(B)^{(1)} \rightarrow 0$ is exact. Thus we may choose an element $\theta \in G(B)^{(1)}$ mapping to ξ .

Consider the graded A -algebra

$$C = A[x_1, \dots, x_n, y_1, \dots, y_n] / (\sum a_{ij}x_j, \sum a_{ij}y_j)$$

There are three graded A -algebra homomorphisms $p_1, p_2, m : B \rightarrow C$ defined by the rules

$$p_1(x_i) = x_i, \quad p_2(x_i) = y_i, \quad m(x_i) = x_i + y_i.$$

We will show that the element

$$\tau = G(m)(\theta) - G(p_1)(\theta) - G(p_2)(\theta) \in G(C)$$

is zero. First, τ maps to zero in $L(C)$ by a direct calculation. Hence τ is an element of $\underline{M}(C)$. Moreover, since m, p_1, p_2 are graded algebra maps we see that $\tau \in G(C)^{(1)}$ and since $\underline{M} \subset G$ we conclude

$$\tau \in \underline{M}(C)^{(1)} = M \otimes_A C_1.$$

We may write uniquely $\tau = \underline{M}(p_1)(\tau_1) + \underline{M}(p_2)(\tau_2)$ with $\tau_i \in M \otimes_A B_1 = \underline{M}(B)^{(1)}$ because $C_1 = p_1(B_1) \oplus p_2(B_1)$. Consider the ring map $q_1 : C \rightarrow B$ defined by $x_i \mapsto x_i$ and $y_i \mapsto 0$. Then $\underline{M}(q_1)(\tau) = \underline{M}(q_1)(\underline{M}(p_1)(\tau_1) + \underline{M}(p_2)(\tau_2)) = \tau_1$. On the other hand, because $q_1 \circ m = q_1 \circ p_1$ we see that $G(q_1)(\tau) = -G(q_1 \circ p_2)(\tau)$. Since $q_1 \circ p_2$ factors as $B \rightarrow A \rightarrow B$ we see that $G(q_1 \circ p_2)(\tau)$ is in $G(B)^{(0)}$, see Lemma 42.3.7. Hence $\tau_1 = 0$ because it is in $G(B)^{(0)} \cap \underline{M}(B)^{(1)} \subset G(B)^{(0)} \cap G(B)^{(1)} = 0$. Similarly $\tau_2 = 0$, whence $\tau = 0$.

Since $\theta \in G(B)$ we obtain a transformation of functors

$$\psi : L(-) = \text{Hom}_A(B, -) \rightarrow G(-)$$

by mapping $f : B \rightarrow C$ to $G(f)(\theta)$. Since θ is a lift of ξ the map ψ is a right inverse of $G \rightarrow L$. In terms of ψ the statements proved above have the following meaning: $\tau = 0$ means that ψ is additive and $\theta \in G(B)^{(1)}$ implies that for any A -algebra D we have $\psi(ul) = u\psi(l)$ in $G(D)$ for $l \in L(D)$ and $u \in D^*$ a unit. This implies that ψ is a morphism of module-valued functors, see Lemma 42.3.13. Clearly this implies that $G \cong \underline{M} \oplus L$ and we win. \square

Remark 42.3.15. Let A be a ring. The proof of Lemma 42.3.14 shows that any extension $0 \rightarrow \underline{M} \rightarrow E \rightarrow L \rightarrow 0$ of module-valued functors on Alg_A with L linearly adequate splits. It uses only the following properties of the module-valued functor $F = \underline{M}$:

- (1) $F(B) \otimes_B B' \rightarrow F(B')$ is an isomorphism for a flat ring map $B \rightarrow B'$, and
- (2) $F(C)^{(1)} = F(p_1)(F(B)^{(1)}) \oplus F(p_2)(F(B)^{(1)})$ where $B = A[x_1, \dots, x_n] / (\sum a_{ij}x_j)$ and $C = A[x_1, \dots, x_n, y_1, \dots, y_n] / (\sum a_{ij}x_j, \sum a_{ij}y_j)$.

These two properties hold for any adequate functor F ; details omitted. Hence we see that L is a projective object of the abelian category of adequate functors.

Lemma 42.3.16. *Let A be a ring. Let $0 \rightarrow F \rightarrow G \rightarrow H \rightarrow 0$ be a short exact sequence of module-valued functors on Alg_A . If F and H are adequate, so is G .*

Proof. Choose an exact sequence $0 \rightarrow F \rightarrow \underline{M} \rightarrow \underline{N}$. If we can show that $(\underline{M} \oplus G)/F$ is adequate, then G is the kernel of the map of adequate functors $(\underline{M} \oplus G)/F \rightarrow \underline{N}$, hence adequate by Lemma 42.3.11. Thus we may assume $F = \underline{M}$.

We can choose a surjection $L \rightarrow H$ where L is a direct sum of linearly adequate functors, see Lemma 42.3.6. If we can show that the pullback $G \times_H L$ is adequate, then G is the cokernel of the map $\text{Ker}(L \rightarrow H) \rightarrow G \times_H L$ hence adequate by Lemma 42.3.10. Thus we may assume that $H = \bigoplus L_i$ is a direct sum of linearly adequate functors. By Lemma 42.3.14 each of the pullbacks $G \times_H L_i$ is adequate. By Lemma 42.3.12 we see that $\bigoplus G \times_H L_i$ is adequate. Then G is the cokernel of

$$\bigoplus_{i \neq i'} F \longrightarrow \bigoplus G \times_H L_i$$

where ξ in the summand (i, i') maps to $(0, \dots, 0, \xi, 0, \dots, 0, -\xi, 0, \dots, 0)$ with nonzero entries in the summands i and i' . Thus G is adequate by Lemma 42.3.10. \square

Lemma 42.3.17. *Let $A \rightarrow A'$ be a ring map. If F is an adequate functor on Alg_A , then its restriction F' to $\text{Alg}_{A'}$ is adequate too.*

Proof. Choose an exact sequence $0 \rightarrow F \rightarrow \underline{M} \rightarrow \underline{N}$. Then $F'(B') = F(B') = \text{Ker}(M \otimes_A B' \rightarrow N \otimes_A B')$. Since $M \otimes_A B' = M \otimes_A A' \otimes_{A'} B'$ and similarly for N we see that F' is the kernel of $\underline{M} \otimes_A A' \rightarrow \underline{N} \otimes_A A'$. \square

Lemma 42.3.18. *Let $A \rightarrow A'$ be a ring map. If F' is an adequate functor on $\text{Alg}_{A'}$, then the module-valued functor $F : B \mapsto F'(A' \otimes_A B)$ on Alg_A is adequate too.*

Proof. Choose an exact sequence $0 \rightarrow F' \rightarrow \underline{M}' \rightarrow \underline{N}'$. Then

$$\begin{aligned} F(B) &= F'(A' \otimes_A B) \\ &= \text{Ker}(M' \otimes_{A'} (A' \otimes_A B) \rightarrow N' \otimes_{A'} (A' \otimes_A B)) \\ &= \text{Ker}(M' \otimes_A B \rightarrow N' \otimes_A B) \end{aligned}$$

Thus F is the kernel of $\underline{M} \rightarrow \underline{N}$ where $M = M'$ and $N = N'$ viewed as A -modules. \square

Lemma 42.3.19. *Let $A = A_1 \times \dots \times A_n$ be a product of rings. An adequate functor over A is the same thing as a sequence F_1, \dots, F_n of adequate functors F_i over A_i .*

Proof. This is true because an A -algebra B is canonically a product $B_1 \times \dots \times B_n$ and the same thing holds for A -modules. Setting $F(B) = \prod F_i(B_i)$ gives the correspondence. Details omitted. \square

Lemma 42.3.20. *Let $A \rightarrow A'$ be a ring map and let F be a module-valued functor on Alg_A such that*

- (1) *the restriction F' of F to the category of A' -algebras is adequate, and*
- (2) *for any A -algebra B the sequence*

$$0 \rightarrow F(B) \rightarrow F(B \otimes_A A') \rightarrow F(B \otimes_A A' \otimes_A A')$$

is exact.

Then F is adequate.

Proof. The functors $B \rightarrow F(B \otimes_A A')$ and $B \mapsto F(B \otimes_A A' \otimes_A A')$ are adequate, see Lemmas 42.3.18 and 42.3.17. Hence F as a kernel of a map of adequate functors is adequate, see Lemma 42.3.11. \square

42.4. Higher exts of adequate functors

Let A be a ring. In Lemma 42.3.16 we have seen that any extension of adequate functors in the category of module-valued functors on Alg_A is adequate. In this section we show that the same remains true for higher ext groups.

Lemma 42.4.1. *Let A be a ring. For every module-valued functor F on Alg_A there exists a morphism $Q(F) \rightarrow F$ of module-valued functors on Alg_A such that (1) $Q(F)$ is adequate and (2) for every adequate functor G the map $\text{Hom}(G, Q(F)) \rightarrow \text{Hom}(G, F)$ is a bijection.*

Proof. Choose a set $\{L_i\}_{i \in I}$ of linearly adequate functors such that every linearly adequate functor is isomorphic to one of the L_i . This is possible. Suppose that we can find $Q(F) \rightarrow F$ with (1) and (2)' or every $i \in I$ the map $\text{Hom}(L_i, Q(F)) \rightarrow \text{Hom}(L_i, F)$ is a bijection. Then (2) holds. Namely, combining Lemmas 42.3.6 and 42.3.11 we see that every adequate functor G sits in an exact sequence

$$K \rightarrow L \rightarrow G \rightarrow 0$$

with K and L direct sums of linearly adequate functors. Hence (2)' implies that $\text{Hom}(L, Q(F)) \rightarrow \text{Hom}(L, F)$ and $\text{Hom}(K, Q(F)) \rightarrow \text{Hom}(K, F)$ are bijections, whence the same thing for G .

Consider the category \mathcal{I} whose objects are pairs (i, φ) where $i \in I$ and $\varphi : L_i \rightarrow F$ is a morphism. A morphism $(i, \varphi) \rightarrow (i', \varphi')$ is a map $\psi : L_i \rightarrow L_{i'}$ such that $\varphi' \circ \psi = \varphi$. Set

$$Q(F) = \text{colim}_{(i, \varphi) \in \text{Ob}(\mathcal{I})} L_i$$

There is a natural map $Q(F) \rightarrow F$, by Lemma 42.3.12 it is adequate, and by construction it has property (2)'. \square

Lemma 42.4.2. *Let A be a ring. Denote \mathcal{P} the category of module-valued functors on Alg_A and \mathcal{A} the category of adequate functors on Alg_A . Denote $i : \mathcal{A} \rightarrow \mathcal{P}$ the inclusion functor. Denote $Q : \mathcal{P} \rightarrow \mathcal{A}$ the construction of Lemma 42.4.1. Then*

- (1) i is fully faithful, exact, and its image is a weak Serre subcategory,
- (2) \mathcal{P} has enough injectives,
- (3) the functor Q is a right adjoint to i hence left exact,
- (4) Q transforms injectives into injectives,
- (5) \mathcal{A} has enough injectives.

Proof. This lemma just collects some facts we have already seen so far. Part (1) is clear from the definitions, the characterization of weak Serre subcategories (see Homology, Lemma 12.9.3), and Lemmas 42.3.10, 42.3.11, and 42.3.16. Recall that \mathcal{P} is equivalent to the category $P\text{Mod}((\text{Aff}/\text{Spec}(A))_\tau, \mathcal{O})$. Hence (2) by Injectives, Proposition 19.8.5. Part (3) follows from Lemma 42.4.1 and Categories, Lemma 4.24.4. Parts (4) and (5) follow from Homology, Lemmas 12.25.1 and 12.25.3. \square

Let A be a ring. As in Formal Deformation Theory, Section 68.10 given an A -algebra B and an B -module N we set $B[N]$ equal to the R -algebra with underlying B -module $B \oplus N$ with multiplication given by $(b, m)(b', m') = (bb', bm' + b'm)$. Note that this construction is functorial in the pair (B, N) where morphism $(B, N) \rightarrow (B', N')$ is given by an A -algebra map $B \rightarrow B'$ and an B -module map $N \rightarrow N'$. In some sense the functor TF of pairs defined in the following lemma is the tangent

space of F . Below we will only consider pairs (B, N) such that $B[N]$ is an object of Alg_A .

Lemma 42.4.3. *Let A be a ring. Let F be a module valued functor. For every $B \in \text{Ob}(\text{Alg}_A)$ and B -module N there is a canonical decomposition*

$$F(B[N]) = F(B) \oplus TF(B, N)$$

characterized by the following properties

- (1) $TF(B, N) = \text{Ker}(F(B[N]) \rightarrow F(B))$,
- (2) there is a B -module structure $TF(B, N)$ compatible with $B[N]$ -module structure on $F(B[N])$,
- (3) TF is a functor from the category of pairs (B, N) ,
- (4) there are canonical maps $N \otimes_B F(B) \rightarrow TF(B, N)$ inducing a transformation between functors defined on the category of pairs (B, N) ,
- (5) $TF(B, 0) = 0$ and the map $TF(B, N) \rightarrow TF(B, N')$ is zero when $N \rightarrow N'$ is the zero map.

Proof. Since $B \rightarrow B[N] \rightarrow B$ is the identity we see that $F(B) \rightarrow F(B[N])$ is a direct summand whose complement is $TF(N, B)$ as defined in (1). This construction is functorial in the pair (B, N) simply because given a morphism of pairs $(B, N) \rightarrow (B', N')$ we obtain a commutative diagram

$$\begin{array}{ccccc} B' & \longrightarrow & B'[N'] & \longrightarrow & B' \\ \uparrow & & \uparrow & & \uparrow \\ B & \longrightarrow & B[N] & \longrightarrow & B \end{array}$$

in Alg_A . The B -module structure comes from the $B[N]$ -module structure and the ring map $B \rightarrow B[N]$. The map in (4) is the composition

$$N \otimes_B F(B) \longrightarrow B[N] \otimes_{B[N]} F(B[N]) \longrightarrow F(B[N])$$

whose image is contained in $TF(B, N)$. (The first arrow uses the inclusions $N \rightarrow B[N]$ and $F(B) \rightarrow F(B[N])$ and the second arrow is the multiplication map.) If $N = 0$, then $B = B[N]$ hence $TF(B, 0) = 0$. If $N \rightarrow N'$ is zero then it factors as $N \rightarrow 0 \rightarrow N'$ hence the induced map is zero since $TF(B, 0) = 0$. \square

Let A be a ring. Let M be an A -module. Then the module-valued functor \underline{M} has tangent space $T\underline{M}$ given by the rule $T\underline{M}(B, N) = N \otimes_A M$. In particular, for B given, the functor $N \mapsto T\underline{M}(B, N)$ is additive and right exact. It turns out this also holds for injective module-valued functors.

Lemma 42.4.4. *Let A be a ring. Let I be an injective object of the category of module-valued functors. Then for any $B \in \text{Ob}(\text{Alg}_A)$ and short exact sequence $0 \rightarrow N_1 \rightarrow N \rightarrow N_2 \rightarrow 0$ of B -modules the sequence*

$$TI(B, N_1) \rightarrow TI(B, N) \rightarrow TI(B, N_2) \rightarrow 0$$

is exact.

Proof. We will use the results of Lemma 42.4.3 without further mention. Denote $h : \text{Alg}_A \rightarrow \text{Sets}$ the functor given by $h(C) = \text{Mor}_A(B[N], C)$. Similarly for h_1 and h_2 . The map $B[N] \rightarrow B[N_2]$ corresponding to the surjection $N \rightarrow N_2$ is surjective.

It corresponds to a map $h_2 \rightarrow h$ such that $h_2(C) \rightarrow h(C)$ is injective for all A -algebras C . On the other hand, there are two maps $p, q : h \rightarrow h_1$, corresponding to the zero map $N_1 \rightarrow N$ and the injection $N_1 \rightarrow N$. Note that

$$h_2 \longrightarrow h \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} h_1$$

is an equalizer diagram. Denote \mathcal{O}_h the module-valued functor $C \mapsto \bigoplus_{h(C)} C$. Similarly for \mathcal{O}_{h_1} and \mathcal{O}_{h_2} . Note that

$$\text{Hom}_{\mathcal{P}}(\mathcal{O}_h, F) = F(B[N])$$

where \mathcal{P} is the category of of module-valued functors on Alg_A . We claim there is an equalizer diagram

$$\mathcal{O}_{h_2} \longrightarrow \mathcal{O}_h \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} \mathcal{O}_{h_1}$$

in \mathcal{P} . Namely, suppose that $C \in \text{Ob}(\text{Alg}_A)$ and $\xi = \sum_{i=1, \dots, n} c_i \cdot f_i$ where $c_i \in C$ and $f_i : B[N] \rightarrow C$ is an element of $\mathcal{O}_h(C)$. If $p(\xi) = q(\xi)$, then we see that

$$\sum c_i \cdot f_i \circ z = \sum c_i \cdot f_i \circ y$$

where $z, y : B[N_1] \rightarrow B[N]$ are the maps $z : (b, m_1) \mapsto (b, 0)$ and $y : (b, m_1) \mapsto (b, m_1)$. This means that for every i there exists a j such that $f_j \circ z = f_i \circ y$. Clearly, this implies that $f_i(N_1) = 0$, i.e., f_i factors through a unique map $\bar{f}_i : B[N_2] \rightarrow C$. Hence ξ is the image of $\bar{\xi} = \sum c_i \cdot \bar{f}_i$. Since I is injective, it transforms this equalizer diagram into a coequalizer diagram

$$I(B[N_1]) \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} I(B[N]) \longrightarrow I(B[N_2])$$

This diagram is compatible with the direct sum decompositions $I(B[N]) = I(B) \oplus TI(B, N)$ and $I(B[N_i]) = I(B) \oplus TI(B, N_i)$. The zero map $N \rightarrow N_1$ induces the zero map $TI(B, N) \rightarrow TI(B, N_1)$. Thus we see that the coequalizer property above means we have an exact sequence $TI(B, N_1) \rightarrow TI(B, N) \rightarrow TI(B, N_2) \rightarrow 0$ as desired. \square

Lemma 42.4.5. *Let A be a ring. Let F be a module-valued functor such that for any $B \in \text{Ob}(\text{Alg}_A)$ the functor $TF(B, -)$ on B -modules transforms a short exact sequence of B -modules into a right exact sequence. Then*

- (1) $TF(B, N_1 \oplus N_2) = TF(B, N_1) \oplus TF(B, N_2)$,
- (2) *there is a second functorial B -module structure on $TF(B, N)$ defined by setting $x \cdot b = TF(B, b \cdot 1_N)(x)$ for $x \in TF(B, N)$ and $b \in B$,*
- (3) *the canonical map $N \otimes_B F(B) \rightarrow TF(B, N)$ of Lemma 42.4.3 is B -linear also with respect to the second B -module structure,*
- (4) *given a finitely presented B -module N there is a canonical isomorphism $TF(B, B) \otimes_B N \rightarrow TF(B, N)$ where the tensor product uses the second B -module structure on $TF(B, B)$.*

Proof. We will use the results of Lemma 42.4.3 without further mention. The maps $N_1 \rightarrow N_1 \oplus N_2$ and $N_2 \rightarrow N_1 \oplus N_2$ give a map $TF(B, N_1) \oplus TF(B, N_2) \rightarrow TF(B, N_1 \oplus N_2)$ which is injective since the maps $N_1 \oplus N_2 \rightarrow N_1$ and $N_1 \oplus N_2 \rightarrow N_2$ induce an inverse. Since TF is right exact we see that $TF(B, N_1) \rightarrow TF(B, N_1 \oplus N_2) \rightarrow TF(B, N_2) \rightarrow 0$ is exact. Hence $TF(B, N_1) \oplus TF(B, N_2) \rightarrow TF(B, N_1 \oplus N_2)$ is an isomorphism. This proves (1).

To see (2) the only thing we need to show is that $x \cdot (b_1 + b_2) = x \cdot b_1 + x \cdot b_2$. (Associativity and additivity are clear.) To see this consider

$$N \xrightarrow{(b_1, b_2)} N \oplus N \xrightarrow{\pm} N$$

and apply $TF(B, -)$.

Part (3) follows immediately from the fact that $N \otimes_B F(B) \rightarrow TF(B, N)$ is functorial in the pair (B, N) .

Suppose N is a finitely presented B -module. Choose a presentation $B^{\oplus m} \rightarrow B^{\oplus n} \rightarrow N \rightarrow 0$. This gives an exact sequence

$$TF(B, B^{\oplus m}) \rightarrow TF(B, B^{\oplus n}) \rightarrow TF(B, N) \rightarrow 0$$

by right exactness of $TF(B, -)$. By part (1) we can write $TF(B, B^{\oplus m}) = TF(B, B)^{\oplus m}$ and $TF(B, B^{\oplus n}) = TF(B, B)^{\oplus n}$. Next, suppose that $B^{\oplus m} \rightarrow B^{\oplus n}$ is given by the matrix $T = (b_{ij})$. Then the induced map $TF(B, B)^{\oplus m} \rightarrow TF(B, B)^{\oplus n}$ is given by the matrix with entries $TF(B, b_{ij} \cdot 1_B)$. This combined with right exactness of \otimes proves (4). \square

Example 42.4.6. Let F be a module-valued functor as in Lemma 42.4.5. It is not always the case that the two module structures on $TF(B, N)$ agree. Here is an example. Suppose $A = \mathbf{F}_p$ where p is a prime. Set $F(B) = B$ but with B -module structure given by $b \cdot x = b^p x$. Then $TF(B, N) = N$ with B -module structure given by $b \cdot x = b^p x$ for $x \in N$. However, the second B -module structure is given by $x \cdot b = bx$. Note that in this case the canonical map $N \otimes_B F(B) \rightarrow TF(B, N)$ is zero as raising an element $n \in B[N]$ to the p th power is zero.

In the following lemma we will frequently use the observation that if $0 \rightarrow F \rightarrow G \rightarrow H \rightarrow 0$ is an exact sequence of module-valued functors on Alg_A , then for any pair (B, N) the sequence $0 \rightarrow TF(B, N) \rightarrow TG(B, N) \rightarrow TH(B, N) \rightarrow 0$ is exact. This follows from the fact that $0 \rightarrow F(B[N]) \rightarrow G(B[N]) \rightarrow H(B[N]) \rightarrow 0$ is exact.

Lemma 42.4.7. *Let A be a ring. For F a module-valued functor on Alg_A say $(*)$ holds if for all $B \in \text{Ob}(\text{Alg}_A)$ the functor $TF(B, -)$ on B -modules transforms a short exact sequence of B -modules into a right exact sequence. Let $0 \rightarrow F \rightarrow G \rightarrow H \rightarrow 0$ be a short exact sequence of module-valued functors on Alg_A .*

- (1) *If $(*)$ holds for F, G then $(*)$ holds for H .*
- (2) *If $(*)$ holds for F, H then $(*)$ holds for G .*
- (3) *If $H' \rightarrow H$ is morphism of module-valued functors on Alg_A and $(*)$ holds for F, G, H , and H' , then $(*)$ holds for $G \times_H H'$.*

Proof. Let B be given. Let $0 \rightarrow N_1 \rightarrow N_2 \rightarrow N_3 \rightarrow 0$ be a short exact sequence of B -modules. Part (1) follows from a diagram chase in the diagram

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & TF(B, N_1) & \longrightarrow & TG(B, N_1) & \longrightarrow & TH(B, N_1) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & TF(B, N_2) & \longrightarrow & TG(B, N_2) & \longrightarrow & TH(B, N_2) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & TF(B, N_3) & \longrightarrow & TG(B, N_3) & \longrightarrow & TH(B, N_3) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & & & \\
 & & 0 & & 0 & & & &
 \end{array}$$

with exact horizontal rows and exact columns involving TF and TG . To prove part (2) we do a diagram chase in the diagram

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & TF(B, N_1) & \longrightarrow & TG(B, N_1) & \longrightarrow & TH(B, N_1) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & TF(B, N_2) & \longrightarrow & TG(B, N_2) & \longrightarrow & TH(B, N_2) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & TF(B, N_3) & \longrightarrow & TG(B, N_3) & \longrightarrow & TH(B, N_3) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & 0 & & & & 0 & &
 \end{array}$$

with exact horizontal rows and exact columns involving TF and TH . Part (3) follows from part (2) as $G \times_H H'$ sits in the exact sequence $0 \rightarrow F \rightarrow G \times_H H' \rightarrow H' \rightarrow 0$. \square

Most of the work in this section was done in order to prove the following key vanishing result.

Lemma 42.4.8. *Let A be a ring. Let M, P be A -modules with P of finite presentation. Then $\text{Ext}_{\mathcal{P}}^i(\underline{P}, \underline{M}) = 0$ for $i > 0$ where \mathcal{P} is the category of module-valued functors on Alg_A .*

Proof. Choose an injective resolution $\underline{M} \rightarrow I^\bullet$ in \mathcal{P} , see Lemma 42.4.2. By Derived Categories, Lemma 13.27.2 any element of $\text{Ext}_{\mathcal{P}}^i(\underline{P}, \underline{M})$ comes from a morphism $\varphi : \underline{P} \rightarrow I^i$ with $d^i \circ \varphi = 0$. We will prove that the Yoneda extension

$$E : 0 \rightarrow \underline{M} \rightarrow I^0 \rightarrow \dots \rightarrow I^{i-1} \times_{\text{Ker}(d^i)} \underline{P} \rightarrow \underline{P} \rightarrow 0$$

of \underline{P} by \underline{M} associated to φ is trivial, which will prove the lemma by Derived Categories, Lemma 13.27.5.

For F a module-valued functor on Alg_A say $(*)$ holds if for all $B \in \text{Ob}(\text{Alg}_A)$ the functor $TF(B, -)$ on B -modules transforms a short exact sequence of B -modules into a right exact sequence. Recall that the module-valued functors $\underline{M}, I^n, \underline{P}$ each have property $(*)$, see Lemma 42.4.4 and the remarks preceding it. By splitting $0 \rightarrow \underline{M} \rightarrow I^\bullet$ into short exact sequences we find that each of the functors $\text{Im}(d^{n-1}) =$

$\text{Ker}(d^n) \subset I^n$ has property (*) by Lemma 42.4.7 and also that $I^{i-1} \times_{\text{Ker}(d^i)} \underline{P}$ has property (*).

Thus we may assume the Yoneda extension is given as

$$E : 0 \rightarrow \underline{M} \rightarrow F_{i-1} \rightarrow \dots \rightarrow F_0 \rightarrow \underline{P} \rightarrow 0$$

where each of the module-valued functors F_j has property (*). Set $G_j(B) = TF_j(B, B)$ viewed as a B -module via the *second* B -module structure defined in Lemma 42.4.5. Since TF_j is a functor on pairs we see that G_j is a module-valued functor on Alg_A . Moreover, since E is an exact sequence the sequence $G_{j+1} \rightarrow G_j \rightarrow G_{j-1}$ is exact (see remark preceding Lemma 42.4.7). Observe that $T\underline{M}(B, B) = M \otimes_A B = \underline{M}(B)$ and that the two B -module structures agree on this. Thus we obtain a Yoneda extension

$$E' : 0 \rightarrow \underline{M} \rightarrow G_{i-1} \rightarrow \dots \rightarrow G_0 \rightarrow \underline{P} \rightarrow 0$$

Moreover, the canonical maps

$$F_j(B) = B \otimes_B F_j(B) \longrightarrow TF_j(B, B) = G_j(B)$$

of Lemma 42.4.3 (4) are B -linear by Lemma 42.4.5 (3) and functorial in B . Hence a map

$$\begin{array}{ccccccccccc} 0 & \longrightarrow & \underline{M} & \longrightarrow & F_{i-1} & \longrightarrow & \dots & \longrightarrow & F_0 & \longrightarrow & \underline{P} & \longrightarrow & 0 \\ & & \downarrow 1 & & \downarrow & & & & \downarrow & & \downarrow 1 & & \\ 0 & \longrightarrow & \underline{M} & \longrightarrow & G_{i-1} & \longrightarrow & \dots & \longrightarrow & G_0 & \longrightarrow & \underline{P} & \longrightarrow & 0 \end{array}$$

of Yoneda extensions. In particular we see that E and E' have the same class in $\text{Ext}_{\mathcal{P}}^i(\underline{P}, \underline{M})$ by the lemma on Yoneda Exts mentioned above. Finally, let N be a A -module of finite presentation. Then we see that

$$0 \rightarrow T\underline{M}(A, N) \rightarrow TF_{i-1}(A, N) \rightarrow \dots \rightarrow TF_0(A, N) \rightarrow T\underline{P}(A, N) \rightarrow 0$$

is exact. By Lemma 42.4.5 (4) with $B = A$ this translates into the exactness of the sequence of A -modules

$$0 \rightarrow M \otimes_A N \rightarrow G_{i-1}(A) \otimes_A N \rightarrow \dots \rightarrow G_0(A) \otimes_A N \rightarrow P \otimes_A N \rightarrow 0$$

Hence the sequence of A -modules $0 \rightarrow M \rightarrow G_{i-1}(A) \rightarrow \dots \rightarrow G_0(A) \rightarrow P \rightarrow 0$ is universally exact, in the sense that it remains exact on tensoring with any finitely presented A -module N . Let $K = \text{Ker}(G_0(A) \rightarrow P)$ so that we have exact sequences

$$0 \rightarrow K \rightarrow G_0(A) \rightarrow P \rightarrow 0 \quad \text{and} \quad G_2(A) \rightarrow G_1(A) \rightarrow K \rightarrow 0$$

Tensoring the second sequence with N we obtain that $K \otimes_A N = \text{Coker}(G_2(A) \otimes_A N \rightarrow G_1(A) \otimes_A N)$. Exactness of $G_2(A) \otimes_A N \rightarrow G_1(A) \otimes_A N \rightarrow G_0(A) \otimes_A N$ then implies that $K \otimes_A N \rightarrow G_0(A) \otimes_A N$ is injective. By Algebra, Theorem 10.79.3 this means that the A -module extension $0 \rightarrow K \rightarrow G_0(A) \rightarrow P \rightarrow 0$ is exact, and because P is assumed of finite presentation this means the sequence is split, see Algebra, Lemma 10.79.4. Any splitting $P \rightarrow G_0(A)$ defines a map $\underline{P} \rightarrow G_0$ which splits the surjection $G_0 \rightarrow \underline{P}$. Thus the Yoneda extension E' is equivalent to the trivial Yoneda extension and we win. \square

Lemma 42.4.9. *Let A be a ring. Let M be an A -module. Let L be a linearly adequate functor on Alg_A . Then $\text{Ext}_{\mathcal{P}}^i(L, \underline{M}) = 0$ for $i > 0$ where \mathcal{P} is the category of module-valued functors on Alg_A .*

Proof. Since L is linearly adequate there exists an exact sequence

$$0 \rightarrow L \rightarrow \underline{A}^{\oplus m} \rightarrow \underline{A}^{\oplus n} \rightarrow \underline{P} \rightarrow 0$$

Here $P = \text{Coker}(A^{\oplus m} \rightarrow A^{\oplus n})$ is the cokernel of the map of finite free A -modules which is given by the definition of linearly adequate functors. By Lemma 42.4.8 we have the vanishing of $\text{Ext}_{\mathcal{P}}^i(\underline{P}, \underline{M})$ and $\text{Ext}_{\mathcal{P}}^i(\underline{A}, \underline{M})$ for $i > 0$. Let $K = \text{Ker}(\underline{A}^{\oplus n} \rightarrow \underline{P})$. By the long exact sequence of Ext groups associated to the exact sequence $0 \rightarrow K \rightarrow \underline{A}^{\oplus n} \rightarrow \underline{P} \rightarrow 0$ we conclude that $\text{Ext}_{\mathcal{P}}^i(K, \underline{M}) = 0$ for $i > 0$. Repeating with the sequence $0 \rightarrow L \rightarrow \underline{A}^{\oplus m} \rightarrow K \rightarrow 0$ we win. \square

Lemma 42.4.10. *With notation as in Lemma 42.4.2 we have $R^p Q(F) = 0$ for all $p > 0$ and any adequate functor F .*

Proof. Choose an exact sequence $0 \rightarrow F \rightarrow \underline{M}^0 \rightarrow \underline{M}^1$. Set $M^2 = \text{Coker}(M^0 \rightarrow M^1)$ so that $0 \rightarrow F \rightarrow \underline{M}^0 \rightarrow \underline{M}^1 \rightarrow \underline{M}^2 \rightarrow 0$ is a resolution. By Derived Categories, Lemma 13.21.3 we obtain a spectral sequence

$$R^p Q(\underline{M}^q) \Rightarrow R^{p+q} Q(F)$$

Since $Q(\underline{M}^q) = \underline{M}^q$ it suffices to prove $R^p Q(\underline{M}) = 0$, $p > 0$ for any A -module M .

Choose an injective resolution $\underline{M} \rightarrow I^\bullet$ in the category \mathcal{P} . Suppose that $R^i Q(\underline{M})$ is nonzero. Then $\text{Ker}(Q(I^i) \rightarrow Q(I^{i+1}))$ is strictly bigger than the image of $Q(I^{i-1}) \rightarrow Q(I^i)$. Hence by Lemma 42.3.6 there exists a linearly adequate functor L and a map $\varphi : L \rightarrow Q(I^i)$ mapping into the kernel of $Q(I^i) \rightarrow Q(I^{i+1})$ which does not factor through the image of $Q(I^{i-1}) \rightarrow Q(I^i)$. Because Q is a left adjoint to the inclusion functor the map φ corresponds to a map $\varphi' : L \rightarrow I^i$ with the same properties. Thus φ' gives a nonzero element of $\text{Ext}_{\mathcal{P}}^i(L, \underline{M})$ contradicting Lemma 42.4.9. \square

42.5. Adequate modules

In Descent, Section 34.7 we have seen that quasi-coherent modules on a scheme S are the same as quasi-coherent modules on any of the big sites $(\text{Sch}/S)_\tau$ associated to S . We have seen that there are two issues with this identification:

- (1) $QCoh(\mathcal{O}_S) \rightarrow \text{Mod}((\text{Sch}/S)_\tau, \mathcal{O})$, $\mathcal{F} \mapsto \mathcal{F}^a$ is not exact in general, and
- (2) given a quasi-compact and quasi-separated morphism $f : X \rightarrow S$ the functor f_* does not preserve quasi-coherent sheaves on the big sites in general.

Part (1) means that we cannot define a triangulated subcategory of $D(\mathcal{O})$ consisting of complexes whose cohomology sheaves are quasi-coherent. Part (2) means that $Rf_* \mathcal{F}$ isn't a complex with quasi-coherent cohomology sheaves even when \mathcal{F} is quasi-coherent and f is quasi-compact and quasi-separated. Moreover, the examples given in the proofs of Descent, Lemma 34.7.13 and Descent, Proposition 34.7.14 are not of a pathological nature.

In this section we discuss a slightly larger category of \mathcal{O} -modules on $(\text{Sch}/S)_\tau$ with contains the quasi-coherent modules, is abelian, and is preserved under f_* when f is quasi-compact and quasi-separated. To do this, suppose that S is a scheme. Let \mathcal{F} be a presheaf of \mathcal{O} -modules on $(\text{Sch}/S)_\tau$. For any affine object $U = \text{Spec}(A)$ of

$(Sch/S)_\tau$ we can restrict \mathcal{F} to $(Aff/U)_\tau$ to get a presheaf of \mathcal{O} -modules on this site. The corresponding module-valued functor, see Section 42.3, will be denoted

$$F = F_{\mathcal{F},A} : Alg_A \longrightarrow Ab, \quad B \longmapsto \mathcal{F}(\text{Spec}(B))$$

The assignment $\mathcal{F} \mapsto F_{\mathcal{F},A}$ is an exact functor of abelian categories.

Definition 42.5.1. A sheaf of \mathcal{O} -modules \mathcal{F} on $(Sch/S)_\tau$ is *adequate* if there exists a τ -covering $\{\text{Spec}(A_i) \rightarrow S\}_{i \in I}$ such that $F_{\mathcal{F},A_i}$ is adequate for all $i \in I$.

We will see below that the category of adequate \mathcal{O} -modules is independent of the chosen topology τ .

Lemma 42.5.2. *Let S be a scheme. Let \mathcal{F} be an adequate \mathcal{O} -module on $(Sch/S)_\tau$. For any affine scheme $\text{Spec}(A)$ over S the functor $F_{\mathcal{F},A}$ is adequate.*

Proof. Let $\{\text{Spec}(A_i) \rightarrow S\}_{i \in I}$ be a τ -covering such that $F_{\mathcal{F},A_i}$ is adequate for all $i \in I$. We can find a standard affine τ -covering $\{\text{Spec}(A'_j) \rightarrow \text{Spec}(A)\}_{j=1, \dots, m}$ such that $\text{Spec}(A'_j) \rightarrow \text{Spec}(A) \rightarrow S$ factors through $\text{Spec}(A_{i(j)})$ for some $i(j) \in I$. Then we see that $F_{\mathcal{F},A'_j}$ is the restriction of $F_{\mathcal{F},A_{i(j)}}$ to the category of A'_j -algebras. Hence $F_{\mathcal{F},A'_j}$ is adequate by Lemma 42.3.17. By Lemma 42.3.19 the sequence $F_{\mathcal{F},A'_j}$ corresponds to an adequate “product” functor F' over $A' = A'_1 \times \dots \times A'_m$. As \mathcal{F} is a sheaf (for the Zariski topology) this product functor F' is equal to $F_{\mathcal{F},A'}$, i.e., is the restriction of F to A' -algebras. Finally, $\{\text{Spec}(A') \rightarrow \text{Spec}(A)\}$ is a τ -covering. It follows from Lemma 42.3.20 that $F_{\mathcal{F},A}$ is adequate. \square

Lemma 42.5.3. *Let $S = \text{Spec}(A)$ be an affine scheme. The category of adequate \mathcal{O} -modules on $(Sch/S)_\tau$ is equivalent to the category of adequate module-valued functors on Alg_A .*

Proof. Given an adequate module \mathcal{F} the functor $F_{\mathcal{F},A}$ is adequate by Lemma 42.5.2. Given an adequate functor F we choose an exact sequence $0 \rightarrow F \rightarrow \underline{M} \rightarrow \underline{N}$ and we consider the \mathcal{O} -module $\mathcal{F} = \text{Ker}(M^a \rightarrow N^a)$ where M^a denotes the quasi-coherent \mathcal{O} -module on $(Sch/S)_\tau$ associated to the quasi-coherent sheaf \widetilde{M} on S . Note that $F = F_{\mathcal{F},A}$, in particular the module \mathcal{F} is adequate by definition. We omit the proof that the constructions define mutually inverse equivalences of categories. \square

Lemma 42.5.4. *Let $f : T \rightarrow S$ be a morphism of schemes. The pullback $f^*\mathcal{F}$ of an adequate \mathcal{O} -module \mathcal{F} on $(Sch/S)_\tau$ is an adequate \mathcal{O} -module on $(Sch/T)_\tau$.*

Proof. The pullback map $f^* : \text{Mod}((Sch/S)_\tau, \mathcal{O}) \rightarrow \text{Mod}((Sch/T)_\tau, \mathcal{O})$ is given by restriction, i.e., $f^*\mathcal{F}(V) = \mathcal{F}(V)$ for any scheme V over T . Hence this lemma follows immediately from Lemma 42.5.2 and the definition. \square

Here is a characterization of the category of adequate \mathcal{O} -modules. To understand the significance, consider a map $\mathcal{G} \rightarrow \mathcal{H}$ of quasi-coherent \mathcal{O}_S -modules on a scheme S . The cokernel of the associated map $\mathcal{G}^a \rightarrow \mathcal{H}^a$ of \mathcal{O} -modules is quasi-coherent because it is equal to $(\mathcal{H}/\mathcal{G})^a$. But the kernel of $\mathcal{G}^a \rightarrow \mathcal{H}^a$ in general isn't quasi-coherent. However, it is adequate.

Lemma 42.5.5. *Let S be a scheme. Let \mathcal{F} be an \mathcal{O} -module on $(Sch/S)_\tau$. The following are equivalent*

- (1) \mathcal{F} is adequate,

- (2) there exists an affine open covering $S = \bigcup S_i$ and maps of quasi-coherent \mathcal{O}_{S_i} -modules $\mathcal{G}_i \rightarrow \mathcal{H}_i$ such that $\mathcal{F}|_{(Sch/S_i)_\tau}$ is the kernel of $\mathcal{G}_i^a \rightarrow \mathcal{H}_i^a$
- (3) there exists a τ -covering $\{S_i \rightarrow S\}_{i \in I}$ and maps of \mathcal{O}_{S_i} -quasi-coherent modules $\mathcal{G}_i \rightarrow \mathcal{H}_i$ such that $\mathcal{F}|_{(Sch/S_i)_\tau}$ is the kernel of $\mathcal{G}_i^a \rightarrow \mathcal{H}_i^a$,
- (4) there exists a τ -covering $\{f_i : S_i \rightarrow S\}_{i \in I}$ such that each $f_i^* \mathcal{F}$ is adequate,
- (5) for any affine scheme U over S the restriction $\mathcal{F}|_{(Sch/U)_\tau}$ is the kernel of a map $\mathcal{G}^a \rightarrow \mathcal{H}^a$ of quasi-coherent \mathcal{O}_U -modules.

Proof. Let $U = \text{Spec}(A)$ be an affine scheme over S . Set $F = F_{\mathcal{F}, A}$. By definition, the functor F is adequate if and only if there exists a map of A -modules $M \rightarrow N$ such that $F = \text{Ker}(M \rightarrow N)$. Combining with Lemmas 42.5.2 and 42.5.3 we see that (1) and (5) are equivalent.

It is clear that (5) implies (2) and (2) implies (3). If (3) holds then we can refine the covering $\{S_i \rightarrow S\}$ such that each $S_i = \text{Spec}(A_i)$ is affine. Then we see, by the preliminary remarks of the proof, that $F_{\mathcal{F}, A_i}$ is adequate. Thus \mathcal{F} is adequate by definition. Hence (3) implies (1).

Finally, (4) is equivalent to (1) using Lemma 42.5.4 for one direction and that a composition of τ -coverings is a τ -covering for the other. \square

Just like is true for quasi-coherent sheaves the category of adequate modules is independent of the topology.

Lemma 42.5.6. *Let \mathcal{F} be an adequate \mathcal{O} -module on $(Sch/S)_\tau$. For any surjective flat morphism $\text{Spec}(B) \rightarrow \text{Spec}(A)$ of affines over S the extended Čech complex*

$$0 \rightarrow \mathcal{F}(\text{Spec}(A)) \rightarrow \mathcal{F}(\text{Spec}(B)) \rightarrow \mathcal{F}(\text{Spec}(B \otimes_A B)) \rightarrow \dots$$

is exact. In particular \mathcal{F} satisfies the sheaf condition for fpqc coverings, and is a sheaf of \mathcal{O} -modules on $(Sch/S)_{fppf}$.

Proof. With $A \rightarrow B$ as in the lemma let $F = F_{\mathcal{F}, A}$. This functor is adequate by Lemma 42.5.2. By Lemma 42.3.5 since $A \rightarrow B$, $A \rightarrow B \otimes_A B$, etc are flat we see that $F(B) = F(A) \otimes_A B$, $F(B \otimes_A B) = F(A) \otimes_A B \otimes_A B$, etc. Exactness follows from Descent, Lemma 34.3.6.

Thus \mathcal{F} satisfies the sheaf condition for τ -coverings (in particular Zariski coverings) and any faithfully flat covering of an affine by an affine. Arguing as in the proofs of Descent, Lemma 34.5.1 and Descent, Proposition 34.5.2 we conclude that \mathcal{F} satisfies the sheaf condition for all fpqc coverings (made out of objects of $(Sch/S)_\tau$). Details omitted. \square

Lemma 42.5.6 shows in particular that for any pair of topologies τ, τ' the collection of adequate modules for the τ -topology and the τ' -topology are identical (as presheaves of modules on the underlying category Sch/S).

Definition 42.5.7. Let S be a scheme. The category of adequate \mathcal{O} -modules on $(Sch/S)_\tau$ is denoted $\text{Adeq}(\mathcal{O})$ or $\text{Adeq}((Sch/S)_\tau, \mathcal{O})$. If we want to think just about the abelian category of adequate modules without choosing a topology we simply write $\text{Adeq}(S)$.

Lemma 42.5.8. *Let S be a scheme. Let \mathcal{F} be an adequate \mathcal{O} -module on $(Sch/S)_\tau$.*

- (1) *The restriction $\mathcal{F}|_{S_{zar}}$ is a quasi-coherent \mathcal{O}_S -module on the scheme S .*
- (2) *The restriction $\mathcal{F}|_{S_{\acute{e}tale}}$ is the quasi-coherent module associated to $\mathcal{F}|_{S_{zar}}$.*

- (3) For any affine scheme U over S we have $H^q(U, \mathcal{F}) = 0$ for all $q > 0$.
 (4) There is a canonical isomorphism

$$H^q(S, \mathcal{F}|_{S_{Zar}}) = H^q((Sch/S)_\tau, \mathcal{F}).$$

Proof. By Lemma 42.3.5 and Lemma 42.5.2 we see that for any flat morphism of affines $U \rightarrow V$ over S we have $\mathcal{F}(U) = \mathcal{F}(V) \otimes_{\mathcal{O}(V)} \mathcal{O}(U)$. This works in particular if $U \subset V \subset S$ are affine opens of S , hence $\mathcal{F}|_{S_{Zar}}$ is quasi-coherent. Thus (1) holds.

Let $S' \rightarrow S$ be an étale morphism of schemes. Then for $U \subset S'$ affine open mapping into an affine open $V \subset S$ we see that $\mathcal{F}(U) = \mathcal{F}(V) \otimes_{\mathcal{O}(V)} \mathcal{O}(U)$ because $U \rightarrow V$ is étale, hence flat. Therefore $\mathcal{F}|_{S'_{Zar}}$ is the pullback of $\mathcal{F}|_{S_{Zar}}$. This proves (2).

We are going to apply Cohomology on Sites, Lemma 21.11.9 to the site $(Sch/S)_\tau$ with \mathcal{B} the set of affine schemes over S and Cov the set of standard affine τ -coverings. Assumption (3) of the lemma is satisfied by Descent, Lemma 34.7.8 and Lemma 42.5.6 for the case of a covering by a single affine. Hence we conclude that $H^p(U, \mathcal{F}) = 0$ for every affine scheme U over S . This proves (3). In exactly the same way as in the proof of Descent, Proposition 34.7.10 this implies the equality of cohomologies (4). \square

Remark 42.5.9. Let S be a scheme. We have functors $u : QCoh(\mathcal{O}_S) \rightarrow Adeq(\mathcal{O})$ and $v : Adeq(\mathcal{O}) \rightarrow QCoh(\mathcal{O}_S)$. Namely, the functor $u : \mathcal{F} \mapsto \mathcal{F}^a$ comes from taking the associated \mathcal{O} -module which is adequate by Lemma 42.5.5. Conversely, the functor v comes from restriction $v : \mathcal{G} \mapsto \mathcal{G}|_{S_{Zar}}$, see Lemma 42.5.8. Since \mathcal{F}^a can be described as the pullback of \mathcal{F} under a morphism of ringed topoi $((Sch/S)_\tau, \mathcal{O}) \rightarrow (S_{Zar}, \mathcal{O}_S)$, see Descent, Remark 34.7.6 and since restriction is the pushforward we see that u and v are adjoint as follows

$$\text{Hom}_{\mathcal{O}_S}(\mathcal{F}, v\mathcal{G}) = \text{Hom}_{\mathcal{O}}(u\mathcal{F}, \mathcal{G})$$

where \mathcal{O} denotes the structure sheaf on the big site. It is immediate from the description that the adjunction mapping $\mathcal{F} \rightarrow vu\mathcal{F}$ is an isomorphism for all quasi-coherent sheaves.

Lemma 42.5.10. Let S be a scheme. Let \mathcal{F} be a presheaf of \mathcal{O} -modules on $(Sch/S)_\tau$. If for every affine scheme $\text{Spec}(A)$ over S the functor $F_{\mathcal{F}, A}$ is adequate, then the sheafification of \mathcal{F} is an adequate \mathcal{O} -module.

Proof. Let $U = \text{Spec}(A)$ be an affine scheme over S . Set $F = F_{\mathcal{F}, A}$. The sheafification $\mathcal{F}^\# = (\mathcal{F}^+)^+$, see Sites, Section 7.10. By construction

$$(\mathcal{F}^+)^+(U) = \text{colim}_{\mathcal{U}} \check{H}^0(\mathcal{U}, \mathcal{F})$$

where the colimit is over coverings in the site $(Sch/S)_\tau$. Since U is affine it suffices to take the limit over standard affine τ -coverings $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I} = \{\text{Spec}(A_i) \rightarrow \text{Spec}(A)\}_{i \in I}$ of U . Since each $A \rightarrow A_i$ and $A \rightarrow A_i \otimes_A A_j$ is flat we see that

$$\check{H}^0(\mathcal{U}, \mathcal{F}) = \text{Ker}\left(\prod F(A) \otimes_A A_i \rightarrow \prod F(A) \otimes_A A_i \otimes_A A_j\right)$$

by Lemma 42.3.5. Since $A \rightarrow \prod A_i$ is faithfully flat we see that this always is canonically isomorphic to $F(A)$ by Descent, Lemma 34.3.6. Thus the presheaf $(\mathcal{F}^+)^+$ has the same value as \mathcal{F} on all affine schemes over S . Repeating the argument once more we deduce the same thing for $\mathcal{F}^\# = ((\mathcal{F}^+)^+)^+$. Thus $F_{\mathcal{F}, A} = F_{\mathcal{F}^\#, A}$ and we conclude that $\mathcal{F}^\#$ is adequate. \square

Lemma 42.5.11. *Let S be a scheme.*

- (1) *The category $\text{Adeq}(\mathcal{O})$ is abelian.*
- (2) *The functor $\text{Adeq}(\mathcal{O}) \rightarrow \text{Mod}((\text{Sch}/S)_\tau, \mathcal{O})$ is exact.*
- (3) *If $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3 \rightarrow 0$ is a short exact sequence of \mathcal{O} -modules and \mathcal{F}_1 and \mathcal{F}_3 are adequate, then \mathcal{F}_2 is adequate.*
- (4) *The category $\text{Adeq}(\mathcal{O})$ has colimits and $\text{Adeq}(\mathcal{O}) \rightarrow \text{Mod}((\text{Sch}/S)_\tau, \mathcal{O})$ commutes with them.*

Proof. Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a map of adequate \mathcal{O} -modules. To prove (1) and (2) it suffices to show that $\mathcal{K} = \text{Ker}(\varphi)$ and $\mathcal{Q} = \text{Coker}(\varphi)$ computed in $\text{Mod}((\text{Sch}/S)_\tau, \mathcal{O})$ are adequate. Let $U = \text{Spec}(A)$ be an affine scheme over S . Let $F = F_{\mathcal{F}, A}$ and $G = F_{\mathcal{G}, A}$. By Lemmas 42.3.11 and 42.3.10 the kernel K and cokernel Q of the induced map $F \rightarrow G$ are adequate functors. Because the kernel is computed on the level of presheaves, we see that $K = F_{\mathcal{K}, A}$ and we conclude \mathcal{K} is adequate. To prove the result for the cokernel, denote \mathcal{Q}' the presheaf cokernel of φ . Then $Q = F_{\mathcal{Q}', A}$ and $\mathcal{Q} = (\mathcal{Q}')^\#$. Hence \mathcal{Q} is adequate by Lemma 42.5.10.

Let $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3 \rightarrow 0$ is a short exact sequence of \mathcal{O} -modules and \mathcal{F}_1 and \mathcal{F}_3 are adequate. Let $U = \text{Spec}(A)$ be an affine scheme over S . Let $F_i = F_{\mathcal{F}_i, A}$. The sequence of functors

$$0 \rightarrow F_1 \rightarrow F_2 \rightarrow F_3 \rightarrow 0$$

is exact, because for $V = \text{Spec}(B)$ affine over U we have $H^1(V, \mathcal{F}_1) = 0$ by Lemma 42.5.8. Since F_1 and F_3 are adequate functors by Lemma 42.5.2 we see that F_2 is adequate by Lemma 42.3.16. Thus \mathcal{F}_2 is adequate.

Let $\mathcal{I} \rightarrow \text{Adeq}(\mathcal{O})$, $i \mapsto \mathcal{F}_i$ be a diagram. Denote $\mathcal{F} = \text{colim}_i \mathcal{F}_i$ the colimit computed in $\text{Mod}((\text{Sch}/S)_\tau, \mathcal{O})$. To prove (4) it suffices to show that \mathcal{F} is adequate. Let $\mathcal{F}' = \text{colim}_i \mathcal{F}_i$ be the colimit computed in presheaves of \mathcal{O} -modules. Then $\mathcal{F} = (\mathcal{F}')^\#$. Let $U = \text{Spec}(A)$ be an affine scheme over S . Let $F_i = F_{\mathcal{F}_i, A}$. By Lemma 42.3.12 the functor $\text{colim}_i F_i = F_{\mathcal{F}', A}$ is adequate. Lemma 42.5.10 shows that \mathcal{F} is adequate. \square

The following lemma tells us that the total direct image $Rf_*\mathcal{F}$ of an adequate module under a quasi-compact and quasi-separated morphism is a complex whose cohomology sheaves are adequate.

Lemma 42.5.12. *Let $f : T \rightarrow S$ be a quasi-compact and quasi-separated morphism of schemes. For any adequate \mathcal{O}_T -module on $(\text{Sch}/T)_\tau$ the pushforward $f_*\mathcal{F}$ and the higher direct images $R^i f_*\mathcal{F}$ are adequate \mathcal{O}_S -modules on $(\text{Sch}/S)_\tau$.*

Proof. First we explain how to compute the higher direct images. Choose an injective resolution $\mathcal{F} \rightarrow \mathcal{I}^\bullet$. Then $R^i f_*\mathcal{F}$ is the i th cohomology sheaf of the complex $f_*\mathcal{I}^\bullet$. Hence $R^i f_*\mathcal{F}$ is the sheaf associated to the presheaf which associates to an object U/S of $(\text{Sch}/S)_\tau$ the module

$$\begin{aligned} \frac{\text{Ker}(f_*\mathcal{I}^i(U) \rightarrow f_*\mathcal{I}^{i+1}(U))}{\text{Im}(f_*\mathcal{I}^{i-1}(U) \rightarrow f_*\mathcal{I}^i(U))} &= \frac{\text{Ker}(\mathcal{I}^i(U \times_S T) \rightarrow \mathcal{I}^{i+1}(U \times_S T))}{\text{Im}(\mathcal{I}^{i-1}(U \times_S T) \rightarrow \mathcal{I}^i(U \times_S T))} \\ &= H^i(U \times_S T, \mathcal{F}) \\ &= H^i((\text{Sch}/U \times_S T)_\tau, \mathcal{F}|_{(\text{Sch}/U \times_S T)_\tau}) \\ &= H^i(U \times_S T, \mathcal{F}|_{(U \times_S T)_{\text{zar}}}) \end{aligned}$$

The first equality by Topologies, Lemma 33.7.12 (and its analogues for other topologies), the second equality by definition of cohomology of \mathcal{F} over an object of $(Sch/T)_\tau$, the third equality by Cohomology on Sites, Lemma 21.8.1, and the last equality by Lemma 42.5.8. Thus by Lemma 42.5.10 it suffices to prove the claim stated in the following paragraph.

Let A be a ring. Let T be a scheme quasi-compact and quasi-separated over A . Let \mathcal{F} be an adequate \mathcal{O}_T -module on $(Sch/T)_\tau$. For an A -algebra B set $T_B = T \times_{\text{Spec}(A)} \text{Spec}(B)$ and denote $\mathcal{F}_B = \mathcal{F}|_{(T_B)_{zar}}$ the restriction of \mathcal{F} to the small Zariski site of T_B . (Recall that this is a “usual” quasi-coherent sheaf on the scheme T_B , see Lemma 42.5.8.) Claim: The functor

$$B \longmapsto H^q(T_B, \mathcal{F}_B)$$

is adequate. We will prove the lemma by the usual procedure of cutting T into pieces.

Case I: T is affine. In this case the schemes T_B are all affine and $H^q(T_B, \mathcal{F}_B) = 0$ for all $q \geq 1$. The functor $B \mapsto H^0(T_B, \mathcal{F}_B)$ is adequate by Lemma 42.3.18.

Case II: T is separated. Let n be the minimal number of affines needed to cover T . We argue by induction on n . The base case is Case I. Choose an affine open covering $T = V_1 \cup \dots \cup V_n$. Set $V = V_1 \cup \dots \cup V_{n-1}$ and $U = V_n$. Observe that

$$U \cap V = (V_1 \cap V_n) \cup \dots \cup (V_{n-1} \cap V_n)$$

is also a union of $n - 1$ affine opens as T is separated, see Schemes, Lemma 25.21.8. Note that for each B the base changes U_B, V_B and $(U \cap V)_B = U_B \cap V_B$ behave in the same way. Hence we see that for each B we have a long exact sequence

$$0 \rightarrow H^0(T_B, \mathcal{F}_B) \rightarrow H^0(U_B, \mathcal{F}_B) \oplus H^0(V_B, \mathcal{F}_B) \rightarrow H^0((U \cap V)_B, \mathcal{F}_B) \rightarrow H^1(T_B, \mathcal{F}_B) \rightarrow \dots$$

functorial in B , see Cohomology, Lemma 20.9.2. By induction hypothesis the functors $B \mapsto H^q(U_B, \mathcal{F}_B)$, $B \mapsto H^q(V_B, \mathcal{F}_B)$, and $B \mapsto H^q((U \cap V)_B, \mathcal{F}_B)$ are adequate. Using Lemmas 42.3.11 and 42.3.10 we see that our functor $B \mapsto H^q(T_B, \mathcal{F}_B)$ sits in the middle of a short exact sequence whose outer terms are adequate. Thus the claim follows from Lemma 42.3.16.

Case III: General quasi-compact and quasi-separated case. The proof is again by induction on the number n of affines needed to cover T . The base case $n = 1$ is Case I. Choose an affine open covering $T = V_1 \cup \dots \cup V_n$. Set $V = V_1 \cup \dots \cup V_{n-1}$ and $U = V_n$. Note that since T is quasi-separated $U \cap V$ is a quasi-compact open of an affine scheme, hence Case II applies to it. The rest of the argument proceeds in exactly the same manner as in the paragraph above and is omitted. \square

42.6. Parasitic adequate modules

In this section we start comparing adequate modules and quasi-coherent modules on a scheme S . Recall that there are functors $u : QCoh(\mathcal{O}_S) \rightarrow Adeq(\mathcal{O})$ and $v : Adeq(\mathcal{O}) \rightarrow QCoh(\mathcal{O}_S)$ satisfying the adjunction

$$\text{Hom}_{QCoh(\mathcal{O}_S)}(\mathcal{F}, v\mathcal{G}) = \text{Hom}_{Adeq(\mathcal{O})}(u\mathcal{F}, \mathcal{G})$$

and such that $\mathcal{F} \rightarrow vu\mathcal{F}$ is an isomorphism for every quasi-coherent sheaf \mathcal{F} , see Remark 42.5.9. Hence u is a fully faithful embedding and we can identify $QCoh(\mathcal{O}_S)$ with a full subcategory of $Adeq(\mathcal{O})$. The functor v is exact but u is not left exact in general. The kernel of v is the subcategory of parasitic adequate modules.

In Descent, Definition 34.8.1 we give the definition of a parasitic module. For adequate modules the notion does not depend on the chosen topology.

Lemma 42.6.1. *Let S be a scheme. Let \mathcal{F} be an adequate \mathcal{O} -module on $(Sch/S)_\tau$. The following are equivalent:*

- (1) $v\mathcal{F} = 0$,
- (2) \mathcal{F} is parasitic,
- (3) \mathcal{F} is parasitic for the τ -topology,
- (4) $\mathcal{F}(U) = 0$ for all $U \subset S$ open, and
- (5) there exists an affine open covering $S = \bigcup U_i$ such that $\mathcal{F}(U_i) = 0$ for all i .

Proof. The implications (2) \Rightarrow (3) \Rightarrow (4) \Rightarrow (5) are immediate from the definitions. Assume (5). Suppose that $S = \bigcup U_i$ is an affine open covering such that $\mathcal{F}(U_i) = 0$ for all i . Let $V \rightarrow S$ be a flat morphism. There exists an affine open covering $V = \bigcup V_j$ such that each V_j maps into some U_i . As the morphism $V_j \rightarrow S$ is flat, also $V_j \rightarrow U_i$ is flat. Hence the corresponding ring map $A_i = \mathcal{O}(U_i) \rightarrow \mathcal{O}(V_j) = B_j$ is flat. Thus by Lemma 42.5.2 and Lemma 42.3.5 we see that $\mathcal{F}(U_i) \otimes_{A_i} B_j \rightarrow \mathcal{F}(V_j)$ is an isomorphism. Hence $\mathcal{F}(V_j) = 0$. Since \mathcal{F} is a sheaf for the Zariski topology we conclude that $\mathcal{F}(V) = 0$. In this way we see that (5) implies (2).

This proves the equivalence of (2), (3), (4), and (5). As (1) is equivalent to (3) (see Remark 42.5.9) we conclude that all five conditions are equivalent. \square

Let S be a scheme. The subcategory of parasitic adequate modules is a Serre subcategory of $Adeq(\mathcal{O})$. The quotient is the category of quasi-coherent modules.

Lemma 42.6.2. *Let S be a scheme. The subcategory $\mathcal{C} \subset Adeq(\mathcal{O})$ of parasitic adequate modules is a Serre subcategory. Moreover, the functor v induces an equivalence of categories*

$$Adeq(\mathcal{O})/\mathcal{C} = QCoh(\mathcal{O}_S).$$

Proof. The category \mathcal{C} is the kernel of the exact functor $v : Adeq(\mathcal{O}) \rightarrow QCoh(\mathcal{O}_S)$, see Lemma 42.6.1. Hence it is a Serre subcategory by Homology, Lemma 12.9.4. By Homology, Lemma 12.9.6 we obtain an induced exact functor $\bar{v} : Adeq(\mathcal{O})/\mathcal{C} \rightarrow QCoh(\mathcal{O}_S)$. Because u is a right inverse to v we see right away that \bar{v} is essentially surjective. We see that \bar{v} is faithful by Homology, Lemma 12.9.7. Because u is a right inverse to v we finally conclude that \bar{v} is fully faithful. \square

Lemma 42.6.3. *Let $f : T \rightarrow S$ be a quasi-compact and quasi-separated morphism of schemes. For any parasitic adequate \mathcal{O}_T -module on $(Sch/T)_\tau$ the pushforward $f_*\mathcal{F}$ and the higher direct images $R^i f_*\mathcal{F}$ are parasitic adequate \mathcal{O}_S -modules on $(Sch/S)_\tau$.*

Proof. We have already seen in Lemma 42.5.12 that these higher direct images are adequate. Hence it suffices to show that $(R^i f_*\mathcal{F})(U_i) = 0$ for any τ -covering $\{U_i \rightarrow S\}$ open. And $R^i f_*\mathcal{F}$ is parasitic by Descent, Lemma 34.8.3. \square

42.7. Derived categories of adequate modules, I

Let S be a scheme. We continue the discussion started in Section 42.6. The exact functor v induces a functor

$$D(Adeq(\mathcal{O})) \longrightarrow D(QCoh(\mathcal{O}_S))$$

and similarly for bounded versions.

Lemma 42.7.1. *Let S be a scheme. Let $\mathcal{C} \subset \text{Adeq}(\mathcal{O})$ denote the full subcategory consisting of parasitic adequate modules. Then*

$$D(\text{Adeq}(\mathcal{O}))/D_{\mathcal{C}}(\text{Adeq}(\mathcal{O})) = D(\text{QCoh}(\mathcal{O}_S))$$

and similarly for the bounded versions.

Proof. Follows immediately from Derived Categories, Lemma 13.13.3. \square

Next, we look for a description the other way around by looking at the functors

$$K^+(\text{QCoh}(\mathcal{O}_S)) \longrightarrow K^+(\text{Adeq}(\mathcal{O})) \longrightarrow D^+(\text{Adeq}(\mathcal{O})) \longrightarrow D^+(\text{QCoh}(\mathcal{O}_S)).$$

In some cases the derived category of adequate modules is a localization of the homotopy category of complexes of quasi-coherent modules at universal quasi-isomorphisms. Let S be a scheme. A map of complexes $\varphi : \mathcal{F}^\bullet \rightarrow \mathcal{G}^\bullet$ of quasi-coherent \mathcal{O}_S -modules is said to be a *universal quasi-isomorphism* if for every morphism of schemes $f : T \rightarrow S$ the pullback $f^*\varphi$ is a quasi-isomorphism.

Lemma 42.7.2. *Let $U = \text{Spec}(A)$ be an affine scheme. The bounded below derived category $D^+(\text{Adeq}(\mathcal{O}))$ is the localization of $K^+(\text{QCoh}(\mathcal{O}_U))$ at the multiplicative subset of universal quasi-isomorphisms.*

Proof. If $\varphi : \mathcal{F}^\bullet \rightarrow \mathcal{G}^\bullet$ is a morphism of complexes of quasi-coherent \mathcal{O}_U -modules, then $u\varphi : u\mathcal{F}^\bullet \rightarrow u\mathcal{G}^\bullet$ is a quasi-isomorphism if and only if φ is a universal quasi-isomorphism. Hence the collection S of universal quasi-isomorphisms is a saturated multiplicative system compatible with the triangulated structure by Derived Categories, Lemma 13.5.3. Hence $S^{-1}K^+(\text{QCoh}(\mathcal{O}_U))$ exists and is a triangulated category, see Derived Categories, Proposition 13.5.5. We obtain a canonical functor $\text{can} : S^{-1}K^+(\text{QCoh}(\mathcal{O}_U)) \rightarrow D^+(\text{Adeq}(\mathcal{O}))$ by Derived Categories, Lemma 13.5.6.

Note that, almost by definition, every adequate module on U has an embedding into a quasi-coherent sheaf, see Lemma 42.5.5. Hence by Derived Categories, Lemma 13.16.4 given $\mathcal{F}^\bullet \in \text{Ob}(K^+(\text{Adeq}(\mathcal{O})))$ there exists a quasi-isomorphism $\mathcal{F}^\bullet \rightarrow u\mathcal{G}^\bullet$ where $\mathcal{G}^\bullet \in \text{Ob}(K^+(\text{QCoh}(\mathcal{O}_U)))$. This proves that can is essentially surjective.

Similarly, suppose that \mathcal{F}^\bullet and \mathcal{G}^\bullet are bounded below complexes of quasi-coherent \mathcal{O}_U -modules. A morphism in $D^+(\text{Adeq}(\mathcal{O}))$ between these consists of a pair $f : u\mathcal{F}^\bullet \rightarrow \mathcal{H}^\bullet$ and $s : u\mathcal{G}^\bullet \rightarrow \mathcal{H}^\bullet$ where s is a quasi-isomorphism. Pick a quasi-isomorphism $s' : \mathcal{H}^\bullet \rightarrow u\mathcal{E}^\bullet$. Then we see that $s' \circ f : \mathcal{F}^\bullet \rightarrow \mathcal{E}^\bullet$ and the universal quasi-isomorphism $s' \circ s : \mathcal{G}^\bullet \rightarrow \mathcal{E}^\bullet$ give a morphism in $S^{-1}K^+(\text{QCoh}(\mathcal{O}_U))$ mapping to the given morphism. This proves the "fully" part of full faithfulness. Faithfulness is proved similarly. \square

Lemma 42.7.3. *Let $U = \text{Spec}(A)$ be an affine scheme. The inclusion functor*

$$\text{Adeq}(\mathcal{O}) \rightarrow \text{Mod}((\text{Sch}/U)_\tau, \mathcal{O})$$

has a right adjoint A^1 . Moreover, the adjunction mapping $A(\mathcal{F}) \rightarrow \mathcal{F}$ is an isomorphism for every adequate module \mathcal{F} .

¹This is the "adequator".

Proof. By Topologies, Lemma 33.7.11 (and similarly for the other topologies) we may work with \mathcal{O} -modules on $(\text{Aff}/U)_\tau$. Denote \mathcal{P} the category of module-valued functors on Alg_A and \mathcal{A} the category of adequate functors on Alg_A . Denote $i : \mathcal{A} \rightarrow \mathcal{P}$ the inclusion functor. Denote $Q : \mathcal{P} \rightarrow \mathcal{A}$ the construction of Lemma 42.4.1. We have the commutative diagram

$$(42.7.3.1) \quad \begin{array}{ccccc} \text{Adeq}(\mathcal{O}) & \xrightarrow{k} & \text{Mod}((\text{Aff}/U)_\tau, \mathcal{O}) & \xrightarrow{j} & \text{PMod}((\text{Aff}/U)_\tau, \mathcal{O}) \\ \parallel & & & & \parallel \\ \mathcal{A} & \xrightarrow{i} & & & \mathcal{P} \end{array}$$

The left vertical equality is Lemma 42.5.3 and the right vertical equality was explained in Section 42.3. Define $A(\mathcal{F}) = Q(j(\mathcal{F}))$. Since j is fully faithful it follows immediately that A is a right adjoint of the inclusion functor k . Also, since k is fully faithful too, the final assertion follows formally. \square

The functor A is a right adjoint hence left exact. Since the inclusion functor is exact, see Lemma 42.5.11 we conclude that A transforms injectives into injectives, and that the category $\text{Adeq}(\mathcal{O})$ has enough injectives, see Homology, Lemma 12.25.3 and Injectives, Theorem 19.8.4. This also follows from the equivalence in (42.7.3.1) and Lemma 42.4.2.

Lemma 42.7.4. *Let $U = \text{Spec}(A)$ be an affine scheme. For any object \mathcal{F} of $\text{Adeq}(\mathcal{O})$ we have $R^p A(\mathcal{F}) = 0$ for all $p > 0$ where A is as in Lemma 42.7.3.*

Proof. With notation as in the proof of Lemma 42.7.3 choose an injective resolution $k(\mathcal{F}) \rightarrow \mathcal{I}^\bullet$ in the category of \mathcal{O} -modules on $(\text{Aff}/U)_\tau$. By Cohomology on Sites, Lemmas 21.12.2 and Lemma 42.5.8 the complex $j(\mathcal{I}^\bullet)$ is exact. On the other hand, each $j(\mathcal{I}^n)$ is an injective object of the category of presheaves of modules by Cohomology on Sites, Lemma 21.12.1. It follows that $R^p A(\mathcal{F}) = R^p Q(j(k(\mathcal{F})))$. Hence the result now follows from Lemma 42.4.10. \square

Let S be a scheme. By the discussion in Section 42.5 the embedding $\text{Adeq}(\mathcal{O}) \subset \text{Mod}((\text{Sch}/S)_\tau, \mathcal{O})$ exhibits $\text{Adeq}(\mathcal{O})$ as a weak Serre subcategory of the category of all \mathcal{O} -modules. Denote

$$D_{\text{Adeq}}(\mathcal{O}) \subset D(\mathcal{O}) = D(\text{Mod}((\text{Sch}/S)_\tau, \mathcal{O}))$$

the triangulated subcategory of complexes whose cohomology sheaves are adequate, see Derived Categories, Section 13.13. We obtain a canonical functor

$$D(\text{Adeq}(\mathcal{O})) \longrightarrow D_{\text{Adeq}}(\mathcal{O})$$

see Derived Categories, Equation (13.13.1.1).

Lemma 42.7.5. *If $U = \text{Spec}(A)$ is an affine scheme, then the bounded below version*

$$(42.7.5.1) \quad D^+(\text{Adeq}(\mathcal{O})) \longrightarrow D^+_{\text{Adeq}}(\mathcal{O})$$

of the functor above is an equivalence.

Proof. Let $A : \text{Mod}(\mathcal{O}) \rightarrow \text{Adeq}(\mathcal{O})$ be the right adjoint to the inclusion functor constructed in Lemma 42.7.3. Since A is left exact and since $\text{Mod}(\mathcal{O})$ has enough injectives, A has a right derived functor $RA : D^+_{\text{Adeq}}(\mathcal{O}) \rightarrow D^+(\text{Adeq}(\mathcal{O}))$. We claim that RA is a quasi-inverse to (42.7.5.1). To see this the key fact is that if \mathcal{F} is an

adequate module, then the adjunction map $\mathcal{F} \rightarrow RA(\mathcal{F})$ is a quasi-isomorphism by Lemma 42.7.4.

Namely, to prove the lemma in full it suffices to show:

- (1) Given $\mathcal{F}^\bullet \in K^+(Adeq(\mathcal{O}))$ the canonical map $\mathcal{F}^\bullet \rightarrow RA(\mathcal{F}^\bullet)$ is a quasi-isomorphism, and
- (2) given $\mathcal{G}^\bullet \in K^+(Mod(\mathcal{O}))$ the canonical map $RA(\mathcal{G}^\bullet) \rightarrow \mathcal{G}^\bullet$ is a quasi-isomorphism.

Both (1) and (2) follow from the key fact via a spectral sequence argument using one of the spectral sequences of Derived Categories, Lemma 13.21.3. Some details omitted. \square

Lemma 42.7.6. *Let $U = \text{Spec}(A)$ be an affine scheme. Let \mathcal{F} and \mathcal{G} be adequate \mathcal{O} -modules. For any $i \geq 0$ the natural map*

$$\text{Ext}_{Adeq(\mathcal{O})}^i(\mathcal{F}, \mathcal{G}) \longrightarrow \text{Ext}_{Mod(\mathcal{O})}^i(\mathcal{F}, \mathcal{G})$$

is an isomorphism.

Proof. By definition these ext groups are computed as hom sets in the derived category. Hence this follows immediately from Lemma 42.7.5. \square

42.8. Pure extensions

We want to characterize extensions of quasi-coherent sheaves on the big site of an affine schemes in terms of algebra. To do this we introduce the following notion.

Definition 42.8.1. Let A be a ring.

- (1) An A -module P is said to be *pure projective* if for every universally exact sequence $0 \rightarrow K \rightarrow M \rightarrow N \rightarrow 0$ of A -module the sequence $0 \rightarrow \text{Hom}_A(P, K) \rightarrow \text{Hom}_A(P, M) \rightarrow \text{Hom}_A(P, N) \rightarrow 0$ is exact.
- (2) An A -module I is said to be *pure injective* if for every universally exact sequence $0 \rightarrow K \rightarrow M \rightarrow N \rightarrow 0$ of A -module the sequence $0 \rightarrow \text{Hom}_A(N, I) \rightarrow \text{Hom}_A(M, I) \rightarrow \text{Hom}_A(K, I) \rightarrow 0$ is exact.

Let's characterize pure projectives.

Lemma 42.8.2. *Let A be a ring.*

- (1) *A module is pure projective if and only if it is a direct summand of a direct sum of finitely presented A -modules.*
- (2) *For any module M there exists a universally exact sequence $0 \rightarrow N \rightarrow P \rightarrow M \rightarrow 0$ with P pure projective.*

Proof. First note that a finitely presented A -module is pure projective by Algebra, Theorem 10.79.3. Hence a direct summand of a direct sum of finitely presented A -modules is indeed pure projective. Let M be any A -module. Write $M = \text{colim}_{i \in I} P_i$ as a filtered colimit of finitely presented A -modules. Consider the sequence

$$0 \rightarrow N \rightarrow \bigoplus P_i \rightarrow M \rightarrow 0.$$

For any finitely presented A -module P the map $\text{Hom}_A(P, \bigoplus P_i) \rightarrow \text{Hom}_A(P, M)$ is surjective, as any map $P \rightarrow M$ factors through some P_i . Hence by Algebra, Theorem 10.79.3 this sequence is universally exact. This proves (2). If now M is pure projective, then the sequence is split and we see that M is a direct summand of $\bigoplus P_i$. \square

Let's characterize pure injectives.

Lemma 42.8.3. *Let A be a ring. For any A -module M set $M^\wedge = \text{Hom}_{\mathbf{Z}}(M, \mathbf{Q}/\mathbf{Z})$.*

- (1) *For any A -module M the A -module M^\wedge is pure injective.*
- (2) *An A -module I is pure injective if and only if the map $I \rightarrow (I^\wedge)^\wedge$ splits.*
- (3) *For any module M there exists a universally exact sequence $0 \rightarrow M \rightarrow I \rightarrow N \rightarrow 0$ with I pure injective.*

Proof. We will use the properties of the functor $M \mapsto M^\wedge$ found in More on Algebra, Section 15.42 without further mention. Part (1) holds because $\text{Hom}_A(N, M^\wedge) = \text{Hom}_{\mathbf{Z}}(N \otimes_A M, \mathbf{Q}/\mathbf{Z})$ and because \mathbf{Q}/\mathbf{Z} is injective in the category of abelian groups. Hence if $I \rightarrow (I^\wedge)^\wedge$ is split, then I is pure injective. We claim that for any A -module M the evaluation map $ev : M \rightarrow (M^\wedge)^\wedge$ is universally injective. To see this note that $ev^\wedge : ((M^\wedge)^\wedge)^\wedge \rightarrow M^\wedge$ has a right inverse, namely $ev' : M^\wedge \rightarrow ((M^\wedge)^\wedge)^\wedge$. Then for any A -module N applying the exact faithful functor $^\wedge$ to the map $N \otimes_A M \rightarrow N \otimes_A (M^\wedge)^\wedge$ gives

$$\text{Hom}_A(N, ((M^\wedge)^\wedge)^\wedge) = \left(N \otimes_A (M^\wedge)^\wedge \right)^\wedge \rightarrow \left(N \otimes_A M \right)^\wedge = \text{Hom}_A(N, M^\wedge)$$

which is surjective by the existence of the right inverse. The claim follows. The claim implies (3) and the necessity of the condition in (2). \square

Before we continue we make the following observation which we will use frequently in the rest of this section.

Lemma 42.8.4. *Let A be a ring.*

- (1) *Let $L \rightarrow M \rightarrow N$ be a universally exact sequence of A -modules. Let $K = \text{Im}(M \rightarrow N)$. Then $K \rightarrow N$ is universally injective.*
- (2) *Any universally exact complex can be split into universally exact short exact sequences.*

Proof. Proof of (1). For any A -module T the sequence $L \otimes_A T \rightarrow M \otimes_A T \rightarrow K \otimes_A T \rightarrow 0$ is exact by right exactness of \otimes . By assumption the sequence $L \otimes_A T \rightarrow M \otimes_A T \rightarrow N \otimes_A T$ is exact. Combined this shows that $K \otimes_A T \rightarrow N \otimes_A T$ is injective.

Part (2) means the following: Suppose that M^\bullet is a universally exact complex of A -modules. Set $K^i = \text{Ker}(d^i) \subset M^i$. Then the short exact sequences $0 \rightarrow K^i \rightarrow M^i \rightarrow K^{i+1} \rightarrow 0$ are universally exact. This follows immediately from part (1). \square

Definition 42.8.5. Let A be a ring. Let M be an A -module.

- (1) *A pure projective resolution $P_\bullet \rightarrow M$ is a universally exact sequence*

$$\dots \rightarrow P_1 \rightarrow P_0 \rightarrow M \rightarrow 0$$

with each P_i pure projective.

- (2) *A pure injective resolution $M \rightarrow I^\bullet$ is a universally exact sequence*

$$0 \rightarrow M \rightarrow I^0 \rightarrow I^1 \rightarrow \dots$$

with each I^i pure injective.

These resolutions satisfy the usual uniqueness properties among the class of all universally exact left or right resolutions.

Lemma 42.8.6. *Let A be a ring.*

(1) Any A -module has a pure projective resolution.

Let $M \rightarrow N$ be a map of A -modules. Let $P_\bullet \rightarrow M$ be a pure projective resolution and let $N_\bullet \rightarrow N$ be a universally exact resolution.

(2) There exists a map of complexes $P_\bullet \rightarrow N_\bullet$ inducing the given map

$$M = \text{Coker}(P_1 \rightarrow P_0) \rightarrow \text{Coker}(N_1 \rightarrow N_0) = N$$

(3) two maps $\alpha, \beta : P_\bullet \rightarrow N_\bullet$ inducing the same map $M \rightarrow N$ are homotopic.

Proof. Part (1) follows immediately from Lemma 42.8.2. Before we prove (2) and (3) note that by Lemma 42.8.4 we can split the universally exact complex $N_\bullet \rightarrow N \rightarrow 0$ into universally exact short exact sequences $0 \rightarrow K_0 \rightarrow N_0 \rightarrow N \rightarrow 0$ and $0 \rightarrow K_i \rightarrow N_i \rightarrow K_{i-1} \rightarrow 0$.

Proof of (2). Because P_0 is pure projective we can find a map $P_0 \rightarrow N_0$ lifting the map $P_0 \rightarrow M \rightarrow N$. We obtain an induced map $P_1 \rightarrow F_0 \rightarrow N_0$ which ends up in K_0 . Since P_1 is pure projective we may lift this to a map $P_1 \rightarrow N_1$. This in turn induces a map $P_2 \rightarrow P_1 \rightarrow N_1$ which maps to zero into N_0 , i.e., into K_1 . Hence we may lift to get a map $P_2 \rightarrow N_2$. Repeat.

Proof of (3). To show that α, β are homotopic it suffices to show the difference $\gamma = \alpha - \beta$ is homotopic to zero. Note that the image of $\gamma_0 : P_0 \rightarrow N_0$ is contained in K_0 . Hence we may lift γ_0 to a map $h_0 : P_0 \rightarrow N_1$. Consider the map $\gamma'_1 = \gamma_1 - h_0 \circ d_{P,1} : P_1 \rightarrow N_1$. By our choice of h_0 we see that the image of γ'_1 is contained in K_1 . Since P_1 is pure projective may lift γ'_1 to a map $h_1 : P_1 \rightarrow N_2$. At this point we have $\gamma_1 = h_0 \circ d_{F,1} + d_{N,2} \circ h_1$. Repeat. \square

Lemma 42.8.7. Let A be a ring.

(1) Any A -module has a pure injective resolution.

Let $M \rightarrow N$ be a map of A -modules. Let $M \rightarrow M^\bullet$ be a universally exact resolution and let $N \rightarrow I^\bullet$ be a pure injective resolution.

(2) There exists a map of complexes $M^\bullet \rightarrow I^\bullet$ inducing the given map

$$M = \text{Ker}(M^0 \rightarrow M^1) \rightarrow \text{Ker}(I^0 \rightarrow I^1) = N$$

(3) two maps $\alpha, \beta : M^\bullet \rightarrow I^\bullet$ inducing the same map $M \rightarrow N$ are homotopic.

Proof. This lemma is dual to Lemma 42.8.6. The proof is identical, except one has to reverse all the arrows. \square

Using the material above we can define pure extension groups as follows. Let A be a ring and let M, N be A -modules. Choose a pure injective resolution $N \rightarrow I^\bullet$. By Lemma 42.8.7 the complex

$$\text{Hom}_A(M, I^\bullet)$$

is well defined up to homotopy. Hence its i th cohomology module is a well defined invariant of M and N .

Definition 42.8.8. Let A be a ring and let M, N be A -modules. The i th pure extension module $\text{Pext}_A^i(M, N)$ is the i th cohomology module of the complex $\text{Hom}_A(M, I^\bullet)$ where I^\bullet is a pure injective resolution of N .

Warning: It is not true that an exact sequence of A -modules gives rise to a long exact sequence of pure extension groups. (You need a universally exact sequence for this.) We collect some facts which are obvious from the material above.

Lemma 42.8.9. *Let A be a ring.*

- (1) $Pext_A^i(M, N) = 0$ for $i > 0$ whenever N is pure injective,
- (2) $Pext_A^i(M, N) = 0$ for $i > 0$ whenever M is pure projective, in particular if M is an A -module of finite presentation,
- (3) $Pext_A^i(M, N)$ is also the i th cohomology module of the complex $\text{Hom}_A(P_\bullet, N)$ where P_\bullet is a pure projective resolution of M .

Proof. To see (3) consider the double complex

$$A^{\bullet, \bullet} = \text{Hom}_A(P_\bullet, I^\bullet)$$

Each of its rows is exact except in degree 0 where its cohomology is $\text{Hom}_A(M, I^q)$. Each of its columns is exact except in degree 0 where its cohomology is $\text{Hom}_A(P_p, N)$. Hence the two spectral sequences associated to this complex in Homology, Section 12.22 degenerate, giving the equality. \square

42.9. Higher exts of quasi-coherent sheaves on the big site

It turns out that the module-valued functor \underline{I} associated to a pure injective module I gives rise to an injective object in the category of adequate functors on Alg_A . Warning: It is not true that a pure projective module gives rise to a projective object in the category of adequate functors. We do have plenty of projective objects, namely, the linearly adequate functors.

Lemma 42.9.1. *Let A be a ring. Let \mathcal{A} be the category of adequate functors on Alg_A . The injective objects of \mathcal{A} are exactly the functors \underline{I} where I is a pure injective A -module.*

Proof. Let I be an injective object of \mathcal{A} . Choose an embedding $I \rightarrow \underline{M}$ for some A -module M . As I is injective we see that $\underline{M} = I \oplus F$ for some module-valued functor F . Then $M = I(A) \oplus F(A)$ and it follows that $I = I(A)$. Thus we see that any injective object is of the form \underline{I} for some A -module I . It is clear that the module I has to be pure injective since any universally exact sequence $0 \rightarrow M \rightarrow N \rightarrow L \rightarrow 0$ gives rise to an exact sequence $0 \rightarrow \underline{M} \rightarrow \underline{N} \rightarrow \underline{L} \rightarrow 0$ of \mathcal{A} .

Finally, suppose that I is a pure injective A -module. Choose an embedding $\underline{I} \rightarrow J$ into an injective object of \mathcal{A} (see Lemma 42.4.2). We have seen above that $J = \underline{I}'$ for some A -module I' which is pure injective. As $\underline{I} \rightarrow \underline{I}'$ is injective the map $I \rightarrow I'$ is universally injective. By assumption on I it splits. Hence \underline{I} is a summand of $J = \underline{I}'$ whence an injective object of the category \mathcal{A} . \square

Let $U = \text{Spec}(A)$ be an affine scheme. Let M be an A -module. We will use the notation M^a to denote the quasi-coherent sheaf of \mathcal{O} -modules on $(\text{Sch}/U)_\tau$ associated to the quasi-coherent sheaf \widetilde{M} on U . Now we have all the notation in place to formulate the following lemma.

Lemma 42.9.2. *Let $U = \text{Spec}(A)$ be an affine scheme. Let M, N be A -modules. For all i we have a canonical isomorphism*

$$\text{Ext}_{\text{Mod}(\mathcal{O})}^i(M^a, N^a) = \text{Pext}_A^i(M, N)$$

functorial in M and N .

Proof. Let us construct a canonical arrow from right to left. Namely, if $N \rightarrow I^\bullet$ is a pure injective resolution, then $M^a \rightarrow (I^\bullet)^a$ is an exact complex of (adequate) \mathcal{O} -modules. Hence any element of $\text{Pext}_A^i(M, N)$ gives rise to a map $N^a \rightarrow M^a[i]$ in $D(\mathcal{O})$, i.e., an element of the group on the left.

To prove this map is an isomorphism, note that we may replace $\text{Ext}_{\text{Mod}(\mathcal{O})}^i(M^a, N^a)$ by $\text{Ext}_{\text{Adeq}(\mathcal{O})}^i(M^a, N^a)$, see Lemma 42.7.6. Let \mathcal{A} be the category of adequate functors on Alg_A . We have seen that \mathcal{A} is equivalent to $\text{Adeq}(\mathcal{O})$, see Lemma 42.5.3; see also the proof of Lemma 42.7.3. Hence now it suffices to prove that

$$\text{Ext}_{\mathcal{A}}^i(\underline{M}, \underline{N}) = \text{Pext}_{\mathcal{A}}^i(M, N)$$

However, this is clear from Lemma 42.9.1 as a pure injective resolution $N \rightarrow I^\bullet$ exactly corresponds to an injective resolution of \underline{N} in \mathcal{A} . □

42.10. Derived categories of adequate modules, II

Let S be a scheme. Denote \mathcal{O}_S the structure sheaf of S and \mathcal{O} the structure sheaf of the big site $(\text{Sch}/S)_\tau$. In Descent, Remark 34.7.4 we constructed a morphism of ringed sites

$$(42.10.0.1) \quad f : ((\text{Sch}/S)_\tau, \mathcal{O}) \longrightarrow (S_{\text{Zar}}, \mathcal{O}_S).$$

In the previous sections have seen that the functor $f_* : \text{Mod}(\mathcal{O}) \rightarrow \text{Mod}(\mathcal{O}_S)$ transforms adequate sheaves into quasi-coherent sheaves, and induces an exact functor $v : \text{Adeq}(\mathcal{O}) \rightarrow \text{QCoh}(\mathcal{O}_S)$, and in fact that $f_* = v$ induces an equivalence $\text{Adeq}(\mathcal{O})/\mathcal{C} \rightarrow \text{QCoh}(\mathcal{O}_S)$ where \mathcal{C} is the subcategory of parasitic adequate modules. Moreover, the functor f^* transforms quasi-coherent modules into adequate modules, and induces a functor $u : \text{QCoh}(\mathcal{O}_S) \rightarrow \text{Adeq}(\mathcal{O})$ which is a left adjoint to v .

There is a very similar relationship between $D_{\text{Adeq}}(\mathcal{O})$ and $D_{\text{QCoh}}(S)$. First we explain why the category $D_{\text{Adeq}}(\mathcal{O})$ is independent of the chosen topology.

Remark 42.10.1. Let S be a scheme. Let $\tau, \tau' \in \{\text{Zar}, \text{étale}, \text{smooth}, \text{syntomic}, \text{fppf}\}$. Denote \mathcal{O}_τ , resp. $\mathcal{O}_{\tau'}$ the structure sheaf \mathcal{O} viewed as a sheaf on $(\text{Sch}/S)_\tau$, resp. $(\text{Sch}/S)_{\tau'}$. Then $D_{\text{Adeq}}(\mathcal{O}_\tau)$ and $D_{\text{Adeq}}(\mathcal{O}_{\tau'})$ are canonically isomorphic. This follows from Cohomology on Sites, Lemma 21.22.6. Namely, assume τ is stronger than the topology τ' , let $\mathcal{C} = (\text{Sch}/S)_{\text{fppf}}$, and let \mathcal{B} the collection of affine schemes over S . Assumptions (1) and (2) we've seen above. Assumption (3) is clear and assumption (4) follows from Lemma 42.5.8.

Remark 42.10.2. Let S be a scheme. The morphism f see (42.10.0.1) induces adjoint functors $Rf_* : D_{\text{Adeq}}(\mathcal{O}) \rightarrow D_{\text{QCoh}}(S)$ and $Lf^* : D_{\text{QCoh}}(S) \rightarrow D_{\text{Adeq}}(\mathcal{O})$. Moreover $Rf_*Lf^* \cong \text{id}_{D_{\text{QCoh}}(S)}$.

We sketch the proof. By Remark 42.10.1 we may assume the topology τ is the Zariski topology. We will use the existence of the unbounded total derived functors Lf^* and Rf_* on \mathcal{O} -modules and their adjointness, see Cohomology on Sites, Lemma 21.19.1. In this case f_* is just the restriction to the subcategory S_{Zar} of $(\text{Sch}/S)_{\text{Zar}}$. Hence it is clear that $Rf_* = f_*$ induces $Rf_* : D_{\text{Adeq}}(\mathcal{O}) \rightarrow D_{\text{QCoh}}(S)$. Suppose that \mathcal{G}^\bullet is an object of $D_{\text{QCoh}}(S)$. We may choose a system $\mathcal{K}_1^\bullet \rightarrow \mathcal{K}_2^\bullet \rightarrow \dots$ of

bounded above complexes of flat \mathcal{O}_S -modules whose transition maps are termwise split injectives and a diagram

$$\begin{array}{ccccc} \mathcal{K}_1^\bullet & \longrightarrow & \mathcal{K}_2^\bullet & \longrightarrow & \dots \\ \downarrow & & \downarrow & & \\ \tau_{\leq 1}\mathcal{G}^\bullet & \longrightarrow & \tau_{\leq 2}\mathcal{G}^\bullet & \longrightarrow & \dots \end{array}$$

with the properties (1), (2), (3) listed in Derived Categories, Lemma 13.28.1 where \mathcal{P} is the collection of flat \mathcal{O}_S -modules. Then $Lf^*\mathcal{G}^\bullet$ is computed by $\text{colim } f^*\mathcal{K}_n^\bullet$, see Cohomology on Sites, Lemmas 21.18.1 and 21.18.3 (note that our sites have enough points by Étale Cohomology, Lemma 44.30.1). We have to see that $H^i(Lf^*\mathcal{G}^\bullet) = \text{colim } H^i(f^*\mathcal{K}_n^\bullet)$ is adequate for each i . By Lemma 42.5.11 we conclude that it suffices to show that each $H^i(f^*\mathcal{K}_n^\bullet)$ is adequate.

The adequacy of $H^i(f^*\mathcal{K}_n^\bullet)$ is local on S , hence we may assume that $S = \text{Spec}(A)$ is affine. Because S is affine $D_{QCoh}(S) = D(QCoh(\mathcal{O}_S))$, see the discussion in Derived Categories of Schemes, Section 35.3. Hence there exists a quasi-isomorphism $\mathcal{F}^\bullet \rightarrow \mathcal{K}_n^\bullet$ where \mathcal{F}^\bullet is a bounded above complex of flat quasi-coherent modules. Then $f^*\mathcal{F}^\bullet \rightarrow f^*\mathcal{K}_n^\bullet$ is a quasi-isomorphism, and the cohomology sheaves of $f^*\mathcal{F}^\bullet$ are adequate.

The final assertion $Rf_*Lf^* \cong \text{id}_{D_{QCoh}(S)}$ follows from the explicit description of the functors above. (In plain English: if \mathcal{F} is quasi-coherent and $p > 0$, then $L_p f^* \mathcal{F}$ is a parasitic adequate module.)

Remark 42.10.3. Remark 42.10.2 above implies we have an equivalence of derived categories

$$D_{Adeq}(\mathcal{O})/D_{\mathcal{C}}(\mathcal{O}) \longrightarrow D_{QCoh}(S)$$

where \mathcal{C} is the category of parasitic adequate modules. Namely, it is clear that $D_{\mathcal{C}}(\mathcal{O})$ is the kernel of Rf_* , hence a functor as indicated. For any object X of $D_{Adeq}(\mathcal{O})$ the map $Lf^*Rf_*X \rightarrow X$ maps to a quasi-isomorphism in $D_{QCoh}(S)$, hence $Lf^*Rf_*X \rightarrow X$ is an isomorphism in $D_{Adeq}(\mathcal{O})/D_{\mathcal{C}}(\mathcal{O})$. Finally, for X, Y objects of $D_{Adeq}(\mathcal{O})$ the map

$$Rf_* : \text{Hom}_{D_{Adeq}(\mathcal{O})/D_{\mathcal{C}}(\mathcal{O})}(X, Y) \rightarrow \text{Hom}_{D_{QCoh}(S)}(Rf_*X, Rf_*Y)$$

is bijective as Lf^* gives an inverse (by the remarks above).

Dualizing Complexes

43.1. Introduction

A reference is the book [Har66].

The goals of this chapter are the following:

- (1) Define what it means to have a dualizing complex ω_A^\bullet over a Noetherian ring A , namely
 - (a) we have $\omega_A^\bullet \in D^+(A)$,
 - (b) the cohomology modules $H^i(\omega_A^\bullet)$ are all finite A -modules,
 - (c) ω_A^\bullet has finite injective dimension, and
 - (d) we have $A \rightarrow R\mathrm{Hom}_A(\omega_A^\bullet, \omega_A^\bullet)$ is a quasi-isomorphism.
- (2) List elementary properties of dualizing complexes.
- (3) Show a dualizing complex gives rise to a dimension function.
- (4) Show a dualizing complex gives rise to a good notion of a reflexive hull.
- (5) Prove the finiteness theorem when a dualizing complex exists.

43.2. Essential surjections and injections

We will mostly work in categories of modules, but we may as well make the definition in general.

Definition 43.2.1. Let \mathcal{A} be an abelian category.

- (1) An injection $A \subset B$ of \mathcal{A} is *essential*, or we say that B is an *essential extension of A* , if every nonzero subobject $B' \subset B$ has nonzero intersection with A .
- (2) A surjection $f : A \rightarrow B$ of \mathcal{A} is *essential* if for every proper subobject $A' \subset A$ we have $f(A') \neq B$.

Some lemmas about this notion.

Lemma 43.2.2. *Let \mathcal{A} be an abelian category.*

- (1) *If $A \subset B$ and $B \subset C$ are essential extensions, then $A \subset C$ is an essential extension.*
- (2) *If $A \subset B$ is an essential extension and $C \subset B$ is a subobject, then $A \cap C \subset C$ is an essential extension.*
- (3) *If $A \rightarrow B$ and $B \rightarrow C$ are essential surjections, then $A \rightarrow C$ is an essential surjection.*
- (4) *Given an essential surjection $f : A \rightarrow B$ and a surjection $A \rightarrow C$ with kernel K , the morphism $C \rightarrow B/f(K)$ is an essential surjection.*

Proof. Omitted. □

Lemma 43.2.3. *Let R be a ring. Let M be an R -module. Let $E = \operatorname{colim} E_i$ be a filtered colimit of R -modules. Suppose given a compatible system of essential injections $M \rightarrow E_i$ of R -modules. Then $M \rightarrow E$ is an essential extension of M .*

Proof. Immediate from the definitions and the fact that filtered colimits are exact (Algebra, Lemma 10.8.9). \square

Lemma 43.2.4. *Let R be a ring. Let $M \subset N$ be R -modules. The following are equivalent*

- (1) $M \subset N$ is an essential extension,
- (2) for all $x \in N$ there exists an $f \in R$ such that $fx \in M$ and $fx \neq 0$.

Proof. Assume (1) and let $x \in N$ be a nonzero element. By (1) we have $Rx \cap M \neq 0$. This implies (2).

Assume (2). Let $N' \subset N$ be a nonzero submodule. Pick $x \in N'$ nonzero. By (2) we can find $f \in R$ with $fx \in M$ and $fx \neq 0$. Thus $N' \cap M \neq 0$. \square

43.3. Injective modules

Some results about injective modules over rings.

Lemma 43.3.1. *Let R be a ring. Any product of injective R -modules is injective.*

Proof. Special case of Homology, Lemma 12.23.3. \square

Lemma 43.3.2. *Let $R \rightarrow S$ be a flat ring map. If E is an injective S -module, then E is injective as an R -module.*

Proof. This is true because $\operatorname{Hom}_R(M, E) = \operatorname{Hom}_S(M \otimes_R S, E)$ by Algebra, Lemma 10.13.3 and the fact that tensoring with S is exact. \square

Lemma 43.3.3. *Let $R \rightarrow S$ be an epimorphism of rings. Let E be an S -module. If E is injective as an R -module, then E is an injective S -module.*

Proof. This is true because $\operatorname{Hom}_R(N, E) = \operatorname{Hom}_S(N, E)$ for any S -module N , see Algebra, Lemma 10.103.14. \square

Lemma 43.3.4. *Let $R \rightarrow S$ be a ring map. If E is an injective R -module, then $\operatorname{Hom}_R(S, E)$ is an injective S -module.*

Proof. This is true because $\operatorname{Hom}_S(N, \operatorname{Hom}_R(S, E)) = \operatorname{Hom}_R(N, E)$ by Algebra, Lemma 10.13.4. \square

Lemma 43.3.5. *Let R be a ring. Let I be an injective R -module. Let $E \subset I$ be a submodule. The following are equivalent*

- (1) E is injective, and
- (2) for all $E \subset E' \subset I$ with $E \subset E'$ essential we have $E = E'$.

In particular, an R -module is injective if and only if every essential extension is trivial.

Proof. The final assertion follows from the first and the fact that the category of R -modules has enough injectives (More on Algebra, Section 15.42).

Assume (1). Let $E \subset E' \subset I$ as in (2). Then the map $\operatorname{id}_E : E \rightarrow E$ can be extended to a map $\alpha : E' \rightarrow E$. The kernel of α has to be zero because it intersects E trivially and E' is an essential extension. Hence $E = E'$.

Assume (2). Let $M \subset N$ be R -modules and let $\varphi : M \rightarrow E$ be an R -module map. In order to prove (1) we have to show that φ extends to a morphism $N \rightarrow E$. Consider the set \mathcal{S} of pairs (M', φ') where $M \subset M' \subset N$ and $\varphi' : M' \rightarrow E$ is an R -module map agreeing with φ on M . We define an ordering on \mathcal{S} by the rule $(M', \varphi') \leq (M'', \varphi'')$ if and only if $M' \subset M''$ and $\varphi''|_{M'} = \varphi'$. It is clear that we can take the maximum of a totally ordered subset of \mathcal{S} . Hence by Zorn's lemma we may assume (M, φ) is a maximal element.

Choose an extension $\psi : N \rightarrow I$ of φ composed with the inclusion $E \rightarrow I$. This is possible as I is injective. If $\psi(N) \subset E$, then ψ is the desired extension. If $\psi(N)$ is not contained in E , then by (2) the inclusion $E \subset E + \psi(N)$ is not essential. Hence we can find a nonzero submodule $K \subset E + \psi(N)$ meeting E in 0. This means that $M' = \psi^{-1}(E + K)$ strictly contains M . Thus we can extend φ to M' using

$$M' \xrightarrow{\psi|_{M'}} E + K \rightarrow (E + K)/K = E$$

This contradicts the maximality of (M, φ) . \square

Example 43.3.6. Let R be a reduced ring. Let $\mathfrak{p} \subset R$ be a minimal prime so that $K = R_{\mathfrak{p}}$ is a field (Algebra, Lemma 10.24.1). Then K is an injective R -module. Namely, we have $\text{Hom}_R(M, K) = \text{Hom}_K(M_{\mathfrak{p}}, K)$ for any R -module M . Since localization is an exact functor and taking duals is an exact functor on K -vector spaces we conclude $\text{Hom}_R(-, K)$ is an exact functor, i.e., K is an injective R -module.

Lemma 43.3.7. *Let R be a ring. Let E be an R -module. The following are equivalent*

- (1) E is an injective R -module, and
- (2) given an ideal $I \subset R$ and a module map $\varphi : I \rightarrow E$ there exists an extension of φ to an R -module map $R \rightarrow E$.

Proof. The implication (1) \Rightarrow (2) follows from the definitions. Thus we assume (2) holds and we prove (1). First proof: Since R is a generator for the category of R -modules, this follows from Injectives, Lemma 19.11.5.

Second proof: We have to show that every essential extension $E \subset E'$ is trivial. Pick $x \in E'$ and set $I = \{f \in R \mid fx \in E\}$. The map $I \rightarrow E$, $f \mapsto fx$ extends to $\psi : R \rightarrow E$ by (2). Then $x' = x - \psi(1)$ is an element of E' whose annihilator in E'/E is I and which is annihilated by I as an element of E' . Thus $Rx' = (R/I)x'$ does not intersect E . Since $E \subset E'$ is an essential extension it follows that $x' \in E$ as desired. \square

Lemma 43.3.8. *Let R be a Noetherian ring. A direct sum of injective modules is injective.*

Proof. Let E_i be a family of injective modules parametrized by a set I . Set $E = \bigcup E_i$. To show that E is injective we use Lemma 43.3.7. Thus let $\varphi : I \rightarrow E$ be a module map from an ideal of R into E . As I is a finite R -module (because R is Noetherian) we can find finitely many elements $i_1, \dots, i_r \in I$ such that φ maps into $\bigcup_{j=1, \dots, r} E_{i_j}$. Then we can extend φ into $\bigcup_{j=1, \dots, r} E_{i_j}$ using the injectivity of the modules E_{i_j} . \square

Lemma 43.3.9. *Let R be a Noetherian ring. Let $S \subset R$ be a multiplicative subset. If E is an injective R -module, then $S^{-1}E$ is an injective $S^{-1}R$ -module.*

Proof. Since $R \rightarrow S^{-1}R$ is an epimorphism of rings, it suffices to show that $S^{-1}E$ is injective as an R -module, see Lemma 43.3.3. To show this we use Lemma 43.3.7. Thus let $I \subset R$ be an ideal and let $\varphi : I \rightarrow S^{-1}E$ be an R -module map. As I is a finitely presented R -module (because R is Noetherian) we can find an $f \in S$ and an R -module map $I \rightarrow E$ such that $f\varphi$ is the composition $I \rightarrow E \rightarrow S^{-1}E$ (Algebra, Lemma 10.10.2). Then we can extend $I \rightarrow E$ to a homomorphism $R \rightarrow E$. Then the composition

$$R \rightarrow E \rightarrow S^{-1}E \xrightarrow{f^{-1}} S^{-1}E$$

is the desired extension of φ to R . \square

Lemma 43.3.10. *Let R be a Noetherian ring. Let I be an injective R -module.*

- (1) *Let $f \in R$. Then $E = \bigcup I[f^n] = I[f^\infty]$ is an injective submodule of I .*
- (2) *Let $J \subset R$ be an ideal. Then the J -power torsion submodule $I[J^\infty]$ is an injective submodule of I .*

Proof. We will use Lemma 43.3.5 to prove (1). Suppose that $E \subset E' \subset I$ and that E' is an essential extension of E . We will show that $E' = E$. If not, then we can find $x \in E'$ and $x \notin E$. Let $J = \{a \in R \mid ax \in E'\}$. Since R is Noetherian we can choose x with J maximal. Since R is Noetherian we can write $J = (g_1, \dots, g_t)$ for some $g_i \in R$. Say f^{n_i} annihilates $g_i x$. Set $n = \max\{n_i\}$. Then $x' = f^n x$ is an element of E' not in E and is annihilated by J . By maximality of J we see that $Rx' = (R/J)x' \cap E = (0)$. Hence E' is not an essential extension of E a contradiction.

To prove (2) write $J = (f_1, \dots, f_t)$. Then $I[J^\infty]$ is equal to

$$(\dots((I[f_1^\infty])[f_2^\infty])\dots)[f_t^\infty]$$

and the result follows from (1) and induction. \square

Lemma 43.3.11. *Let A be a Noetherian ring. Let E be an injective A -module. Then $E \otimes_A A[x]$ has injective-amplitude $[0, 1]$ as an object of $D(A[x])$. In particular, $E \otimes_A A[x]$ has finite injective dimension as an $A[x]$ -module.*

Proof. Let us write $E[x] = E \otimes_A A[x]$. Consider the short exact sequence of $A[x]$ -modules

$$0 \rightarrow E[x] \rightarrow \text{Hom}_A(A[x], E[x]) \rightarrow \text{Hom}_A(A[x], E[x]) \rightarrow 0$$

where the first map sends $p \in E[x]$ to $f \mapsto fp$ and the second map sends φ to $f \mapsto \varphi(xf) - x\varphi(f)$. The second map is surjective because $\text{Hom}_A(A[x], E[x]) = \prod_{n \geq 0} E[x]$ as an abelian group and the map sends (e_n) to $(e_{n+1} - xe_n)$ which is surjective. As an A -module we have $E[x] \cong \bigoplus_{n \geq 0} E$ which is injective by Lemma 43.3.8. Hence the $A[x]$ -module $\text{Hom}_A(A[x], E[x])$ is injective by Lemma 43.3.4 and the proof is complete. \square

43.4. Projective covers

In this section we briefly discuss projective covers.

Definition 43.4.1. Let R be a ring. A surjection $P \rightarrow M$ of R -modules is said to be a *projective cover*, or sometimes a *projective envelope*, if P is a projective R -module and $P \rightarrow M$ is an essential surjection.

Projective covers do not always exist. For example, if k is a field and $R = k[x]$ is the polynomial ring over k , then the module $M = R/(x)$ does not have a projective cover. Namely, for any surjection $f : P \rightarrow M$ with P projective over R , the proper submodule $(x - 1)P$ surjects onto M . Hence f is not essential.

Lemma 43.4.2. *Let R be a ring and let M be an R -module. If a projective cover of M exists, then it is unique up to isomorphism.*

Proof. Let $P \rightarrow M$ and $P' \rightarrow M$ be projective covers. Because P is a projective R -module and $P' \rightarrow M$ is surjective, we can find an R -module map $\alpha : P \rightarrow P'$ compatible with the maps to M . Since $P' \rightarrow M$ is essential, we see that α is surjective. As P' is a projective R -module we can choose a direct sum decomposition $P = \text{Ker}(\alpha) \oplus P'$. Since $P' \rightarrow M$ is surjective and since $P \rightarrow M$ is essential we conclude that $\text{Ker}(\alpha)$ is zero as desired. \square

Here is an example where projective covers exist.

Lemma 43.4.3. *Let $(R, \mathfrak{m}, \kappa)$ be a local ring. Any finite R -module has a projective cover.*

Proof. Let M be a finite R -module. Let $r = \dim_{\kappa}(M/\mathfrak{m}M)$. Choose $x_1, \dots, x_r \in M$ mapping to a basis of $M/\mathfrak{m}M$. Consider the map $f : R^{\oplus r} \rightarrow M$. By Nakayama's lemma this is a surjection (Algebra, Lemma 10.19.1). If $N \subset R^{\oplus r}$ is a proper submodule, then $N/\mathfrak{m}N \rightarrow \kappa^{\oplus r}$ is not surjective (by Nakayama's lemma again) hence $N/\mathfrak{m}N \rightarrow M/\mathfrak{m}M$ is not surjective. Thus f is an essential surjection. \square

43.5. Injective hulls

In this section we briefly discuss injective hulls.

Definition 43.5.1. Let R be a ring. A injection $M \rightarrow I$ of R -modules is said to be an *injective hull* if I is an injective R -module and $M \rightarrow I$ is an essential injection.

Injective hulls always exist.

Lemma 43.5.2. *Let R be a ring. Any R -module has an injective hull.*

Proof. Let M be an R -module. By More on Algebra, Section 15.42 the category of R -modules has enough injectives. Choose an injection $M \rightarrow I$ with I an injective R -module. Consider the set \mathcal{S} of submodules $M \subset E \subset I$ such that E is an essential extension of M . We order \mathcal{S} by inclusion. If $\{E_{\alpha}\}$ is a totally ordered subset of \mathcal{S} , then $\bigcup E_{\alpha}$ is an essential extension of M too (Lemma 43.2.3). Thus we can apply Zorn's lemma and find a maximal element $E \in \mathcal{S}$. We claim $M \subset E$ is an injective hull, i.e., E is an injective R -module. This follows from Lemma 43.3.5. \square

Lemma 43.5.3. *Let R be a ring. Let M, N be R -modules and let $M \rightarrow E$ and $N \rightarrow E'$ be injective hulls. Then*

- (1) *for any R -module map $\varphi : M \rightarrow N$ there exists an R -module map $\psi : E \rightarrow E'$ such that*

$$\begin{array}{ccc} M & \longrightarrow & E \\ \varphi \downarrow & & \downarrow \psi \\ N & \longrightarrow & E' \end{array}$$

commutes,

- (2) if φ is injective, then ψ is injective,
- (3) if φ is an essential injection, then ψ is an isomorphism,
- (4) if φ is an isomorphism, then ψ is an isomorphism,
- (5) if $M \rightarrow I$ is an embedding of M into an injective R -module, then there is an isomorphism $I \cong E \oplus I'$ compatible with the embeddings of M ,

In particular, the injective hull E of M is unique up to isomorphism.

Proof. Part (1) follows from the fact that E' is an injective R -module. Part (2) follows as $\text{Ker}(\psi) \cap M = 0$ and E is an essential extension of M . Assume φ is an essential injection. Then $E \cong \psi(E) \subset E'$ by (2) which implies $E' = \psi(E) \oplus E''$ because E is injective. Since E' is an essential extension of M (Lemma 43.2.2) we get $E'' = 0$. Part (4) is a special case of (3). Assume $M \rightarrow I$ as in (5). Choose a map $\alpha : E \rightarrow I$ extending the map $M \rightarrow I$. Arguing as before we see that α is injective. Thus as before $\alpha(E)$ splits off from I . This proves (5). \square

Example 43.5.4. Let R be a domain with fraction field K . Then $R \subset K$ is an injective hull of R . Namely, by Example 43.3.6 we see that K is an injective R -module and by Lemma 43.2.4 we see that $R \subset K$ is an essential extension.

Definition 43.5.5. An object X of an additive category is called *indecomposable* if it is nonzero and if $X = Y \oplus Z$, then either $Y = 0$ or $Z = 0$.

Lemma 43.5.6. Let R be a ring. Let E be an indecomposable injective R -module. Then

- (1) E is the injective hull of any nonzero submodule of E ,
- (2) the intersection of any two nonzero submodules of E is nonzero,
- (3) $\text{End}_R(E, E)$ is a noncommutative local ring with maximal ideal those $\varphi : E \rightarrow E$ whose kernel is nonzero, and
- (4) the set of zerodivisors on E is a prime ideal \mathfrak{p} of R and E is an injective $R_{\mathfrak{p}}$ -module.

Proof. Part (1) follows from Lemma 43.5.3. Part (2) follows from part (1) and the definition of injective hulls.

Proof of (3). Set $A = \text{End}_R(E, E)$ and $I = \{\varphi \in A \mid \text{Ker}(f) \neq 0\}$. The statement means that I is a two sided ideal and that any $\varphi \in A$, $\varphi \notin I$ is invertible. Suppose φ and ψ are not injective. Then $\text{Ker}(\varphi) \cap \text{Ker}(\psi)$ is nonzero by (2). Hence $\varphi + \psi \in I$. It follows that I is a two sided ideal. If $\varphi \in A$, $\varphi \notin I$, then $E \cong \varphi(E) \subset E$ is an injective submodule, hence $E = \varphi(E)$ because E is indecomposable.

Proof of (4). Consider the ring map $R \rightarrow A$ and let $\mathfrak{p} \subset R$ be the inverse image of the maximal ideal I . Then it is clear that \mathfrak{p} is a prime ideal and that $R \rightarrow A$ extends to $R_{\mathfrak{p}} \rightarrow A$. Thus E is an $R_{\mathfrak{p}}$ -module. It follows from Lemma 43.3.3 that E is injective as an $R_{\mathfrak{p}}$ -module. \square

Lemma 43.5.7. Let $\mathfrak{p} \subset R$ be a prime of a ring R . Let E be the injective hull of R/\mathfrak{p} . Then

- (1) E is indecomposable,
- (2) E is the injective hull of $\kappa(\mathfrak{p})$,
- (3) E is the injective hull of $\kappa(\mathfrak{p})$ over the ring $R_{\mathfrak{p}}$.

Proof. As $R/\mathfrak{p} \subset \kappa(\mathfrak{p})$ we can extend the embedding to a map $\kappa(\mathfrak{p}) \rightarrow E$. Hence (2) holds. For $f \in R$, $f \notin \mathfrak{p}$ the map $f : \kappa(\mathfrak{p}) \rightarrow \kappa(\mathfrak{p})$ is an isomorphism hence the map $f : E \rightarrow E$ is an isomorphism, see Lemma 43.5.3. Thus E is an $R_{\mathfrak{p}}$ -module. It is injective as an $R_{\mathfrak{p}}$ -module by Lemma 43.3.3. Finally, let $E' \subset E$ be a nonzero injective R -submodule. Then $J = (R/\mathfrak{p}) \cap E'$ is nonzero. After shrinking E' we may assume that E' is the injective hull of J (see Lemma 43.5.3 for example). Observe that R/\mathfrak{p} is an essential extension of J for example by Lemma 43.2.4. Hence $E' \rightarrow E$ is an isomorphism by Lemma 43.5.3 part (3). Hence E is indecomposable. \square

Lemma 43.5.8. *Let R be a Noetherian ring. Let E be an indecomposable injective R -module. Then there exists a prime ideal \mathfrak{p} of R such that E is the injective hull of $\kappa(\mathfrak{p})$.*

Proof. Let \mathfrak{p} be the prime ideal found in Lemma 43.5.6. Say $\mathfrak{p} = (f_1, \dots, f_r)$. Pick a nonzero element $x \in \bigcap \text{Ker}(f_i : E \rightarrow E)$, see Lemma 43.5.6. Then $(R_{\mathfrak{p}})x$ is a module isomorphic to $\kappa(\mathfrak{p})$ inside E . We conclude by Lemma 43.5.6. \square

Proposition 43.5.9 (Structure injective modules over Noetherian rings). *Let R be a Noetherian ring. Every injective module is a direct sum of indecomposable injective modules. Every indecomposable injective module is the injective hull of the residue field at a prime.*

Proof. The second statement is Lemma 43.5.8. For the second statement, let I be an injective R -module. We will use transfinite induction to construct $I_{\alpha} \subset I$ for ordinals α which are direct sums of indecomposable injective R -modules $E_{\beta+1}$ for $\beta < \alpha$. For $\alpha = 0$ we let $I_0 = 0$. Suppose given an ordinal α such that I_{α} has been constructed. Then I_{α} is an injective R -module by Lemma 43.3.8. Hence $I \cong I_{\alpha} \oplus I'$. If $I' = 0$ we are done. If not, then I' has an associated prime by Algebra, Lemma 10.62.7. Thus I' contains a copy of R/\mathfrak{p} for some prime \mathfrak{p} . Hence I' contains an indecomposable submodule E by Lemmas 43.5.3 and 43.5.7. Set $I_{\alpha+1} = I_{\alpha} \oplus E_{\alpha}$. If α is a limit ordinal and I_{β} has been constructed for $\beta < \alpha$, then we set $I_{\alpha} = \bigcup_{\beta < \alpha} I_{\beta}$. Observe that $I_{\alpha} = \bigoplus_{\beta < \alpha} E_{\beta+1}$. This concludes the proof. \square

43.6. Duality over Artinian local rings

Let $(R, \mathfrak{m}, \kappa)$ be an artinian local ring. Recall that this implies R is Noetherian and that R has finite length as an R -module. Moreover an R -module is finite if and only if it has finite length. We will use these facts without further mention in this section. Please see Algebra, Sections 10.50 and 10.51 and Algebra, Proposition 10.59.6 for more details.

Lemma 43.6.1. *Let $(R, \mathfrak{m}, \kappa)$ be an artinian local ring. Let E be an injective hull of κ . For every finite R -module M we have*

$$\text{length}_R(M) = \text{length}_R(\text{Hom}_R(M, E))$$

In particular, the injective hull E of κ is a finite R -module.

Proof. Because E is an essential extension of κ we have $\kappa = E[\mathfrak{m}]$ where $E[\mathfrak{m}]$ is the \mathfrak{m} -torsion in E (notation as in More on Algebra, Section 15.63). Hence $\text{Hom}_R(\kappa, E) \cong \kappa$ and the equality of lengths holds for $M = \kappa$. We prove the displayed equality of the lemma by induction on the length of M . If M is nonzero there

exists a surjection $M \rightarrow \kappa$ with kernel M' . Since the functor $M \mapsto \text{Hom}_R(M, E)$ is exact we obtain a short exact sequence

$$0 \rightarrow \text{Hom}_R(\kappa, E) \rightarrow \text{Hom}_R(M, E) \rightarrow \text{Hom}_R(M', E) \rightarrow 0.$$

Additivity of length for this sequence and the sequence $0 \rightarrow M' \rightarrow M \rightarrow \kappa \rightarrow 0$ and the equality for M' (induction hypothesis) and κ implies the equality for M . The final statement of the lemma follows as $E = \text{Hom}_R(R, E)$. \square

Lemma 43.6.2. *Let $(R, \mathfrak{m}, \kappa)$ be an artinian local ring. Let E be an injective hull of κ . For any finite R -module M the evaluation map*

$$M \longrightarrow \text{Hom}_R(\text{Hom}_R(M, E), E)$$

is an isomorphism. In particular $R = \text{Hom}_R(E, E)$.

Proof. Observe that the displayed arrow is injective. Namely, if $x \in M$ is a nonzero element, then there is a nonzero map $Rx \rightarrow \kappa$ which we can extend to a map $\varphi : M \rightarrow E$ that doesn't vanish on x . Since the source and target of the arrow have the same length by Lemma 43.6.1 we conclude it is an isomorphism. The final statement follows on taking $M = R$. \square

To state the next lemma, denote Mod_R^{fg} the category of finite R -modules over a ring R .

Lemma 43.6.3. *Let $(R, \mathfrak{m}, \kappa)$ be an artinian local ring. Let E be an injective hull of κ . The functor $D(-) = \text{Hom}_R(-, E)$ induces an exact anti-equivalence $\text{Mod}_R^{fg} \rightarrow \text{Mod}_R^{fg}$ and $D \circ D \cong \text{id}$.*

Proof. We have seen that $D \circ D = \text{id}$ on Mod_R^{fg} in Lemma 43.6.2. It follows immediately that D is an anti-equivalence. \square

Lemma 43.6.4. *Assumptions and notation as in Lemma 43.6.3. Let $I \subset R$ be an ideal and M a finite R -module. Then*

$$D(M[I]) = D(M)/ID(M) \quad \text{and} \quad D(M/IM) = D(M)[I]$$

Proof. Say $I = (f_1, \dots, f_t)$. Consider the map

$$M^{\oplus t} \xrightarrow{f_1, \dots, f_t} M$$

with cokernel M/IM . Applying the exact functor D we conclude that $D(M/IM)$ is $D(M)[I]$. The other case is proved in the same way. \square

43.7. Injective hull of the residue field

Most of our results will be for Noetherian local rings in this section.

Lemma 43.7.1. *Let $R \rightarrow S$ be a surjective map of local rings with kernel I . Let E be the injective hull of the residue field of R over R . Then $E[I]$ is the injective hull of the residue field of S over S .*

Proof. Observe that $E[I] = \text{Hom}_R(S, E)$ as $S = R/I$. Hence $E[I]$ is an injective S -module by Lemma 43.3.4. Since E is an essential extension of $\kappa = R/\mathfrak{m}_R$ it follows that $E[I]$ is an essential extension of κ as well. The result follows. \square

Lemma 43.7.2. *Let $(R, \mathfrak{m}, \kappa)$ be a local ring. Let E be the injective hull of κ . Let M be a \mathfrak{m} -power torsion R -module with $n = \dim_\kappa(M[\mathfrak{m}]) < \infty$. Then M is isomorphic to a submodule of $E^{\oplus n}$.*

Proof. Observe that $E^{\oplus n}$ is the injective hull of $\kappa^{\oplus n} = M[\mathfrak{m}]$. Thus there is an R -module map $M \rightarrow E^{\oplus n}$ which is injective on $M[\mathfrak{m}]$. Since M is \mathfrak{m} -power torsion the inclusion $M[\mathfrak{m}] \subset M$ is an essential extension (for example by Lemma 43.2.4) we conclude that the kernel of $M \rightarrow E^{\oplus n}$ is zero. \square

Lemma 43.7.3. *Let $(R, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let E be an injective hull of κ over R . Let E_n be an injective hull of κ over R/\mathfrak{m}^n . Then $E = \bigcup E_n$ and $E_n = E[\mathfrak{m}^n]$.*

Proof. We have $E_n = E[\mathfrak{m}^n]$ by Lemma 43.7.1. We have $E = \bigcup E_n$ because $\bigcup E_n = E[\mathfrak{m}^\infty]$ is an injective R -submodule which contains κ , see Lemma 43.3.10. \square

The following lemma tells us the injective hull of the residue field of a Noetherian local ring only depends on the completion.

Lemma 43.7.4. *Let $R \rightarrow S$ be a flat local homomorphism of local Noetherian rings such that $R/\mathfrak{m}_R \cong S/\mathfrak{m}_R S$. Then the injective hull of the residue field of R is the injective hull of the residue field of S .*

Proof. Set $\kappa = R/\mathfrak{m}_R = S/\mathfrak{m}_S$. Let E_R be the injective hull of κ over R . Let E_S be the injective hull of κ over S . Observe that E_S is an injective R -module by Lemma 43.3.2. Choose an extension $E_R \rightarrow E_S$ of the identification of residue fields. This map is an isomorphism by Lemma 43.7.3 because $R \rightarrow S$ induces an isomorphism $R/\mathfrak{m}_R^n \rightarrow S/\mathfrak{m}_S^n$ for all n . \square

Lemma 43.7.5. *Let $(R, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let E be an injective hull of κ over R . Then $\text{Hom}_R(E, E)$ is canonically isomorphic to the completion of R .*

Proof. Write $E = \bigcup E_n$ with $E_n = E[\mathfrak{m}^n]$ as in Lemma 43.7.3. Any endomorphism of E preserves this filtration. Hence

$$\text{Hom}_R(E, E) = \lim \text{Hom}_R(E_n, E_n)$$

The lemma follows as $\text{Hom}_R(E_n, E_n) = \text{Hom}_{R/\mathfrak{m}^n}(E_n, E_n) = R/\mathfrak{m}^n$ by Lemma 43.6.2. \square

Lemma 43.7.6. *Let $(R, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let E be an injective hull of κ over R . Then E satisfies the descending chain condition.*

Proof. If $E \subset M_1 \subset M_2 \dots$ is a sequence of submodules, then

$$\text{Hom}_R(E, E) \rightarrow \text{Hom}_R(M_1, E) \rightarrow \text{Hom}_R(M_2, E) \rightarrow \dots$$

is sequence of surjections. By Lemma 43.7.5 each of these is a module over the completion $R^\wedge = \text{Hom}_R(E, E)$. Since R^\wedge is Noetherian (Algebra, Lemma 10.93.10) the sequence stabilizes: $\text{Hom}_R(M_n, E) = \text{Hom}_R(M_{n+1}, E) = \dots$. Since E is injective, this can only happen if $\text{Hom}_R(M_n/M_{n+1}, E)$ is zero. However, if M_n/M_{n+1} is nonzero, then it contains a nonzero element annihilated by \mathfrak{m} , because E is \mathfrak{m} -power torsion by Lemma 43.7.3. In this case M_n/M_{n+1} has a nonzero map into E , contradicting the assumed vanishing. This finishes the proof. \square

Lemma 43.7.7. *Let $(R, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let E be an injective hull of κ .*

(1) *For an R -module M the following are equivalent:*

- (a) M satisfies the ascending chain condition,
 - (b) M is a finite R -module, and
 - (c) there exist n, m and an exact sequence $R^{\oplus m} \rightarrow R^{\oplus n} \rightarrow M \rightarrow 0$.
- (2) For an R -module M the following are equivalent:
- (a) M satisfies the descending chain condition,
 - (b) M is \mathfrak{m} -power torsion and $\dim_{\kappa}(M[\mathfrak{m}]) < \infty$, and
 - (c) there exist n, m and an exact sequence $0 \rightarrow M \rightarrow E^{\oplus n} \rightarrow E^{\oplus m}$.

Proof. We omit the proof of (1).

Let M be an R -module with the descending chain condition. Let $x \in M$. Then $\mathfrak{m}^n x$ is a descending chain of submodules, hence stabilizes. Thus $\mathfrak{m}^n x = \mathfrak{m}^{n+1} x$ for some n . By Nakayama's lemma (Algebra, Lemma 10.19.1) this implies $\mathfrak{m}^n x = 0$, i.e., x is \mathfrak{m} -power torsion. Since $M[\mathfrak{m}]$ is a vector space over κ it has to be finite dimensional in order to have the descending chain condition.

Assume that M is \mathfrak{m} -power torsion and has a finite dimensional \mathfrak{m} -torsion submodule $M[\mathfrak{m}]$. By Lemma 43.7.2 we see that M is a submodule of $E^{\oplus n}$ for some n . Consider the quotient $N = E^{\oplus n}/M$. By Lemma 43.7.6 the module E has the descending chain condition hence so do $E^{\oplus n}$ and N . Therefore N satisfies (2)(a) which implies N satisfies (2)(b) by the second paragraph of the proof. Thus by Lemma 43.7.2 again we see that N is a submodule of $E^{\oplus m}$ for some m . Thus we have a short exact sequence $0 \rightarrow M \rightarrow E^{\oplus n} \rightarrow E^{\oplus m}$.

Assume we have a short exact sequence $0 \rightarrow M \rightarrow E^{\oplus n} \rightarrow E^{\oplus m}$. Since E satisfies the descending chain condition by Lemma 43.7.6 so does M . \square

Proposition 43.7.8 (Matlis duality). *Let $(R, \mathfrak{m}, \kappa)$ be a complete local Noetherian ring. Let E be an injective hull of κ over R . The functor $D(-) = \text{Hom}_R(-, E)$ induces an anti-equivalence*

$$\left\{ \begin{array}{l} R\text{-modules with the} \\ \text{descending chain condition} \end{array} \right\} \longleftrightarrow \left\{ \begin{array}{l} R\text{-modules with the} \\ \text{ascending chain condition} \end{array} \right\}$$

and we have $D \circ D = \text{id}$ on either side of the equivalence.

Proof. By Lemma 43.7.5 we have $R = \text{Hom}_R(E, E) = D(E)$. Of course we have $E = \text{Hom}_R(R, E) = D(R)$. Since E is injective the functor D is exact. The result now follows immediately from the description of the categories in Lemma 43.7.7. \square

43.8. Local cohomology

Let A be a ring and let $I \subset A$ be a finitely generated ideal (if I is not finitely generated perhaps a different definition should be used). Let $Z = V(I) \subset \text{Spec}(A)$. Recall that the category I^∞ -torsion of I -power torsion modules only depends on the closed subset Z and not on the choice of the finitely generated ideal I such that $Z = V(I)$, see More on Algebra, Lemma 15.62.6. In this section we will consider the functor

$$H_I^0 : \text{Mod}_A \longrightarrow I^\infty\text{-torsion}, \quad M \longmapsto M[I^\infty] = \bigcup M[I^n]$$

which sends M to the submodule of I -power torsion as well as its relationship with the functors

$$\mathcal{H}_Z : \text{Ab}(X) \longrightarrow \text{Ab}(Z)$$

and $\Gamma_Z(-) = \Gamma(Z, \mathcal{H}_Z(-))$ of Cohomology, Section 20.22.

Let A be a ring and let I be a finitely generated ideal. Note that I^∞ -torsion is a Grothendieck abelian category (direct sums exist, filtered colimits are exact, and $\bigoplus A/I^n$ is a generator by More on Algebra, Lemma 15.62.2). Hence the derived category $D(I^\infty\text{-torsion})$ exists, see Injectives, Remark 19.13.3. Our functor H_I^0 is left exact and has a derived extension which we will denote

$$R\Gamma_I : D(A) \longrightarrow D(I^\infty\text{-torsion}).$$

Warning: this functor does not deserve the name local cohomology unless the ring A is Noetherian. The functors H_I^0 , $R\Gamma_I$, and the satellites H_I^p only depend on the closed subset $Z \subset \text{Spec}(A)$ and not on the choice of the finitely generated ideal I such that $V(I) = Z$. However, we insist on using the subscript I for the functors above as the notation $R\Gamma_Z$ is going to be used for a different functor, see (43.8.4.1), which agrees with the functor $R\Gamma_I$ only (as far as we know) in case A is Noetherian (see Lemma 43.8.9).

Lemma 43.8.1. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. The functor $R\Gamma_I$ is right adjoint to the functor $D(I^\infty\text{-torsion}) \rightarrow D(A)$.*

Proof. This follows from the fact that taking I -power torsion submodules is the right adjoint to the inclusion functor $I^\infty\text{-torsion} \rightarrow \text{Mod}_A$. See Derived Categories, Lemma 13.28.4. \square

Lemma 43.8.2. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. For any object K of $D(A)$ we have*

$$R\Gamma_I(K) = \text{hocolim } R\text{Hom}(A/I^n, K)$$

in $D(A)$ and

$$R^q\Gamma_I(K) = \text{colim}_n \text{Ext}_A^q(A/I^n, K)$$

as modules for all $q \in \mathbf{Z}$.

Proof. Let J^\bullet be a K -injective complex representing K . Then

$$R\Gamma_I(K) = J^\bullet[I^\infty] = \text{colim } J^\bullet[I^n] = \text{colim } \text{Hom}_A(A/I^n, J^\bullet)$$

By Derived Categories, Lemma 13.31.4 we obtain the first equality. The second equality is clear because $H^q(\text{Hom}_A(A/I^n, J^\bullet)) = \text{Ext}_A^q(A/I^n, K)$ and because filtered colimits are exact in the category of abelian groups. \square

Lemma 43.8.3. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. Let K^\bullet be a complex of A -modules such that $f : K^\bullet \rightarrow K^\bullet$ is an isomorphism for some $f \in I$, i.e., K^\bullet is a complex of A_f -modules. Then $R\Gamma_I(K^\bullet) = 0$.*

Proof. Namely, in this case the cohomology modules of $R\Gamma_I(K^\bullet)$ are both f -power torsion and f acts by automorphisms. Hence the cohomology modules are zero and hence the object is zero. \square

Let A be a ring and $I \subset A$ a finitely generated ideal. By More on Algebra, Lemma 15.62.5 the category of I -power torsion modules is a Serre subcategory of the category of all A -modules, hence there is a functor

$$(43.8.3.1) \quad D(I^\infty\text{-torsion}) \rightarrow D_{I^\infty\text{-torsion}}(A)$$

see Derived Categories, Section 13.13.

Lemma 43.8.4. *Let A be a ring and let I be a finitely generated ideal. Let M and N be I -power torsion modules.*

- (1) $\text{Hom}_{D(A)}(M, N) = \text{Hom}_{D(I^\infty\text{-torsion})}(M, N),$
- (2) $\text{Ext}_{D(A)}^1(M, N) = \text{Ext}_{D(I^\infty\text{-torsion})}^1(M, N),$
- (3) $\text{Ext}_{D(I^\infty\text{-torsion})}^2(M, N) \rightarrow \text{Ext}_{D(A)}^2(M, N)$ is not surjective in general,
- (4) (43.8.3.1) is not an equivalence in general.

Proof. Parts (1) and (2) follow immediately from the fact that I -power torsion forms a Serre subcategory of Mod_A . Part (4) follows from part (3).

For part (3) let A be a ring with an element $f \in A$ such that $A[f]$ contains a nonzero element x and A contains elements x_n with $f^n x_n = x$. Such a ring A exists because we can take

$$A = \mathbf{Z}[f, x, x_n]/(fx, f^n x_n - x)$$

Given A set $I = (f)$. Then the exact sequence

$$0 \rightarrow A[f] \rightarrow A \xrightarrow{f} A \rightarrow A/fA \rightarrow 0$$

defines an element in $\text{Ext}_A^2(A/fA, A[f])$. We claim this element does not come from an element of $\text{Ext}_{D(f^\infty\text{-torsion})}^2(A/fA, A[f])$. Namely, if it did, then there would be an exact sequence

$$0 \rightarrow A[f] \rightarrow M \rightarrow N \rightarrow A/fA \rightarrow 0$$

where M and N are f -power torsion modules defining the same 2 extension class. Since $A \rightarrow A$ is a complex of free modules and since the 2 extension classes are the same we would be able to find a map

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A[f] & \longrightarrow & A & \longrightarrow & A & \longrightarrow & A/fA & \longrightarrow & 0 \\ & & \downarrow & & \varphi \downarrow & & \psi \downarrow & & \downarrow & & \\ 0 & \longrightarrow & A[f] & \longrightarrow & M & \longrightarrow & N & \longrightarrow & A/fA & \longrightarrow & 0 \end{array}$$

(some details omitted). Then we could replace M by the image of φ and N by the image of ψ . Then M would be a cyclic module, hence $f^n M = 0$ for some n . Considering $\varphi(x_{n+1})$ we get a contradiction with the fact that $f^{n+1}x_n = x$ is nonzero in $A[f]$. □

Let A be a ring and let $I \subset A$ be a finitely generated ideal. Set $Z = V(I) \subset \text{Spec}(A)$. We will construct a functor

$$(43.8.4.1) \quad R\Gamma_Z : D(A) \longrightarrow D_{I^\infty\text{-torsion}}(A).$$

which is right adjoint to the inclusion functor. The cohomology modules of $R\Gamma_Z(K)$ are the *local cohomology groups of K with respect to Z* . In fact, we will show $R\Gamma_Z$ computes cohomology with support in Z for the associated complex of quasi-coherent sheaves on $\text{Spec}(A)$. By Lemma 43.8.4 this functor will in general **not** be equal to $R\Gamma_I(-)$ even viewed as functors into $D(A)$.

Lemma 43.8.5. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. There exists a right adjoint $R\Gamma_Z$ (43.8.4.1) to the inclusion functor $D_{I^\infty\text{-torsion}}(A) \rightarrow D(A)$. In fact, if I is generated by $f_1, \dots, f_r \in A$, then we have*

$$R\Gamma_Z(K) = (A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) \otimes_A^L K$$

functorially in K .

Proof. Say $I = (f_1, \dots, f_r)$ be an ideal. Let K^\bullet be a complex of A -modules. There is a canonical map of complexes

$$(A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) \longrightarrow A.$$

from the extended Čech complex to A . Tensoring with K^\bullet , taking associated total complex, we get a map

$$\text{Tot} \left(K^\bullet \otimes_A (A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) \right) \longrightarrow K^\bullet$$

in $D(A)$. We claim the cohomology modules of the complex on the left are I -power torsion, i.e., the LHS is an object of $D_{I^\infty\text{-torsion}}(A)$. Namely, we have

$$(A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) = \text{colim } K(A, f_1^n, \dots, f_r^n)$$

by More on Algebra, Lemma 15.20.13. Moreover, multiplication by f_i^n on the complex $K(A, f_1^n, \dots, f_r^n)$ is homotopic to zero by More on Algebra, Lemma 15.20.6. Since

$$H^q(LHS) = \text{colim } H^q(\text{Tot}(K^\bullet \otimes_A K(A, f_1^n, \dots, f_r^n)))$$

we obtain our claim. On the other hand, if K^\bullet is an object of $D_{I^\infty\text{-torsion}}(A)$, then the complexes $K^\bullet \otimes_A A_{f_{i_0} \dots f_{i_p}}$ have vanishing cohomology. Hence in this case the map $LHS \rightarrow K^\bullet$ is an isomorphism in $D(A)$. The construction

$$R\Gamma_Z(K^\bullet) = \text{Tot} \left(K^\bullet \otimes_A (A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) \right)$$

is functorial in K^\bullet and defines an exact functor $D(A) \rightarrow D_{I^\infty\text{-torsion}}(A)$ between triangulated categories. It follows formally from the existence of the natural transformation $R\Gamma_Z \rightarrow \text{id}$ given above and the fact that this evaluates to an isomorphism on K^\bullet in the subcategory, that $R\Gamma_Z$ is the desired right adjoint. \square

Lemma 43.8.6. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. Let K^\bullet be a complex of A -modules such that $f : K^\bullet \rightarrow K^\bullet$ is an isomorphism for some $f \in I$, i.e., K^\bullet is a complex of A_f -modules. Then $R\Gamma_Z(K^\bullet) = 0$.*

Proof. Namely, in this case the cohomology modules of $R\Gamma_Z(K^\bullet)$ are both f -power torsion and f acts by automorphisms. Hence the cohomology modules are zero and hence the object is zero. \square

Lemma 43.8.7. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. For $K, L \in D(A)$ general we have*

$$R\Gamma_Z(K \otimes_A^L L) = K \otimes_A^L R\Gamma_Z(L) = R\Gamma_Z(K) \otimes_A^L L = R\Gamma_Z(K) \otimes_A^L R\Gamma_Z(L)$$

If K or L is in $D_{I^\infty\text{-torsion}}(A)$ then so is $K \otimes_A^L L$.

Proof. By Lemma 43.8.5 we know that $R\Gamma_Z$ is given by $C \otimes^L -$ for some $C \in D(A)$. Hence, for $K, L \in D(A)$ general we have

$$R\Gamma_Z(K \otimes_A^L L) = K \otimes_A^L L \otimes_A^L C = K \otimes_A^L R\Gamma_Z(L)$$

The other equalities follow formally from this one. This also implies the last statement of the lemma. \square

The following lemma tells us that the functor $R\Gamma_Z$ is related to local cohomology.

Lemma 43.8.8. *Let A be a ring and let I be a finitely generated ideal. With $Z = V(I) \subset X = \text{Spec}(A)$ there is a functorial isomorphism*

$$R\Gamma_Z(K^\bullet) = R\Gamma_Z(\widetilde{K}^\bullet)$$

where on the left we have (43.8.4.1) and on the right we have the functor of Cohomology, Section 20.22.

Proof. Denote $\mathcal{F}^\bullet = \widetilde{K}^\bullet$ be the complex of quasi-coherent \mathcal{O}_X -modules on X associated to K^\bullet . By Cohomology, Section 20.22 there exists a distinguished triangle

$$R\Gamma_Z(X, \mathcal{F}^\bullet) \rightarrow R\Gamma(X, \mathcal{F}^\bullet) \rightarrow R\Gamma(U, \mathcal{F}^\bullet) \rightarrow R\Gamma_Z(X, \mathcal{F}^\bullet)[1]$$

where $U = X \setminus Z$. We know that $R\Gamma(X, \mathcal{F}^\bullet) = K^\bullet$ for example by Derived Categories of Schemes, Lemma 35.3.4. Say $I = (f_1, \dots, f_r)$. Then we obtain a finite affine open covering $\mathcal{U} : U = D(f_1) \cup \dots \cup D(f_r)$. By Derived Categories of Schemes, Lemma 35.8.4 the alternating Čech complex

$$\text{Tot}(\check{C}_{alt}^\bullet(\mathcal{U}, \mathcal{F}^\bullet))$$

computes $R\Gamma(U, \mathcal{F}^\bullet)$. Working through the definitions we find

$$R\Gamma(U, \mathcal{F}^\bullet) = \text{Tot} \left(K^\bullet \otimes_A \left(\prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r} \right) \right)$$

It is clear that $R\Gamma(X, \mathcal{F}^\bullet) \rightarrow R\Gamma(U, \mathcal{F}^\bullet)$ is given by the map from A into $\prod A_{f_i}$. Hence we conclude that

$$R\Gamma_Z(X, \mathcal{F}^\bullet) = \text{Tot} \left(K^\bullet \otimes_A \left(A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r} \right) \right)$$

By Lemma 43.8.5 this complex computes $R\Gamma_Z(K^\bullet)$ and we see the lemma holds. \square

Let A be a ring and let $I \subset A$ be a finitely generated ideal. Set $Z = V(I) \subset \text{Spec}(A)$. There is a natural transformation of functors

$$(43.8.8.1) \quad (43.8.3.1) \circ R\Gamma_I(-) \longrightarrow R\Gamma_Z(-)$$

Namely, given a complex of A -modules K^\bullet the canonical map $R\Gamma_I(K^\bullet) \rightarrow K^\bullet$ in $D(A)$ factors (uniquely) through $R\Gamma_Z(K^\bullet)$ as $R\Gamma_I(K^\bullet)$ has I -power torsion cohomology modules (see Lemma 43.8.1). In general this map is not an isomorphism (we've seen this above).

Lemma 43.8.9. *Let A be a Noetherian ring and let $I \subset A$ be an ideal. Denote $j : D(I^\infty\text{-torsion}) \rightarrow D_{I^\infty\text{-torsion}}(A)$ the functor (43.8.3.1).*

- (1) *the adjunction $j(R\Gamma_I(K)) \rightarrow K$ is an isomorphism for $K \in D_{I^\infty\text{-torsion}}(A)$,*
- (2) *the functor j is an equivalence,*
- (3) *the transformation of functors (43.8.8.1) is an isomorphism,*

Proof. A formal argument, which we omit, shows that it suffices to prove (1).

Let M be an I -power torsion A -module. Choose an embedding $M \rightarrow J$ into an injective A -module. Then $J[I^\infty]$ is an injective A -module, see Lemma 43.3.10, and we obtain an embedding $M \rightarrow J[I^\infty]$. Thus every I -power torsion module has an injective resolution $M \rightarrow J^\bullet$ with J^n also I -power torsion. It follows that $R\Gamma_I(M) = M$ (this is not a triviality and this is not true in general if A is not Noetherian). Next, suppose that $K \in D_{I^\infty\text{-torsion}}^+(A)$. Then the spectral sequence

$$R^q\Gamma_I(H^p(K)) \Rightarrow R^{p+q}\Gamma_I(K)$$

(Derived Categories, Lemma 13.21.3) converges and above we have seen that only the terms with $q = 0$ are nonzero. Thus we see that $R\Gamma_I(K) \rightarrow K$ is an isomorphism.

Suppose K is an arbitrary object of $D_{I^\infty\text{-torsion}}(A)$. We have

$$R^q\Gamma_I(K) = \operatorname{colim} \operatorname{Ext}_A^q(A/I^n, K)$$

by Lemma 43.8.2. Choose $f_1, \dots, f_r \in A$ generating I . Let $K_n^\bullet = K(A, f_1^n, \dots, f_r^n)$ be the Koszul complex with terms in degrees $-r, \dots, 0$. Since the pro-objects $\{A/I^n\}$ and $\{K_n^\bullet\}$ in $D(A)$ are the same by More on Algebra, Lemma 15.64.18, we see that

$$R^q\Gamma_I(K) = \operatorname{colim} \operatorname{Ext}_A^q(K_n^\bullet, K)$$

Pick any complex K^\bullet of A -modules representing K . Since K_n^\bullet is a finite complex of finite free modules we see that

$$\operatorname{Ext}_A^q(K_n, K) = H^q(\operatorname{Tot}((K_n^\bullet)^\vee \otimes_A K^\bullet))$$

where $(K_n^\bullet)^\vee$ is the dual of the complex K_n^\bullet . See More on Algebra, Lemma 15.55.2. As $(K_n^\bullet)^\vee$ is a complex of finite free A -modules sitting in degrees $0, \dots, r$ we see that the terms of the complex $\operatorname{Tot}((K_n^\bullet)^\vee \otimes_A K^\bullet)$ are the same as the terms of the complex $\operatorname{Tot}((K_n^\bullet)^\vee \otimes_A \tau_{\geq q-r-2}K^\bullet)$ in degrees $q-1$ and higher. Hence we see that

$$\operatorname{Ext}_A^q(K_n, K) = \operatorname{Ext}_A^q(K_n, \tau_{\geq q-r-2}K)$$

for all n . It follows that

$$R^q\Gamma_I(K) = R^q\Gamma_I(\tau_{\geq q-r-2}K) = H^q(\tau_{\geq q-r-2}K) = H^q(K)$$

Thus we see that the map $R\Gamma_I(K) \rightarrow K$ is an isomorphism. \square

Lemma 43.8.10. *If A is a Noetherian ring and $I = (f_1, \dots, f_r)$ an ideal. There are canonical isomorphisms*

$$R\Gamma_I(A) \rightarrow (A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0}f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) \rightarrow R\Gamma_Z(A)$$

in $D(A)$.

Proof. This follows from Lemma 43.8.9 and the computation of the functor $R\Gamma_Z$ in Lemma 43.8.5. \square

Lemma 43.8.11. *Let $A \rightarrow B$ be a ring map. Let $I \subset A$ be a finitely generated ideal. Let $Z = V(I) \subset \operatorname{Spec}(A)$ and $Y = V(IB) \subset \operatorname{Spec}(B)$. For K in $D(A)$ we have $R\Gamma_Z(K) \otimes_A^{\mathbf{L}} B = R\Gamma_Y(K \otimes_A^{\mathbf{L}} B)$.*

Proof. This follows from uniqueness of adjoint functors as both $R\Gamma_Z(-) \otimes_A^{\mathbf{L}} B$ and $R\Gamma_Y(- \otimes_A^{\mathbf{L}} B)$ are right adjoint to the functor $D_{(IB)^\infty\text{-torsion}}(B) \rightarrow D(A)$. Alternatively, one can use the description of $R\Gamma_Z$ and $R\Gamma_Y$ in terms of alternating Čech complexes (Lemma 43.8.5) and use that formation of the extended Čech complex commutes with base change. \square

Lemma 43.8.12. *If $A \rightarrow B$ is a homomorphism of Noetherian rings and $I \subset A$ is an ideal, then in $D(B)$ we have*

$$R\Gamma_I(A) \otimes_A^{\mathbf{L}} B = R\Gamma_Z(A) \otimes_A^{\mathbf{L}} B = R\Gamma_Y(B) = R\Gamma_{IB}(B)$$

where $Y = V(IB) \subset \operatorname{Spec}(B)$.

Proof. Combine Lemmas 43.8.10 and 43.8.11. \square

The following lemma is the analogue of More on Algebra, Lemma 15.64.26 for complexes with torsion cohomologies.

Lemma 43.8.13. *Let $A \rightarrow B$ be a flat ring map and let $I \subset A$ be a finitely generated ideal such that $A/I = B/IB$. Then base change and restriction induce quasi-inverse equivalences $D_{I^\infty\text{-torsion}}(A) = D_{(IB)^\infty\text{-torsion}}(B)$.*

Proof. More precisely the functors are $K \mapsto K \otimes_A^L B$ for K in $D_{I^\infty\text{-torsion}}(A)$ and $M \mapsto M_A$ for M in $D_{(IB)^\infty\text{-torsion}}(B)$. The reason this works is that $H^i(K \otimes_A^L B) = H^i(K) \otimes_A B = H^i(K)$. The first equality holds as $A \rightarrow B$ is flat and the second by More on Algebra, Lemma 15.63.2. \square

The following lemma was shown for Hom and Ext^1 of modules in More on Algebra, Lemmas 15.63.3 and 15.63.8.

Lemma 43.8.14. *Let $A \rightarrow B$ be a flat ring map and let $I \subset A$ be a finitely generated ideal such that $A/I \rightarrow B/IB$ is an isomorphism. For $K \in D_{I^\infty\text{-torsion}}(A)$ and $L \in D(A)$ the map*

$$R\text{Hom}_A(K, L) \longrightarrow R\text{Hom}_B(K \otimes_A B, L \otimes_A B)$$

is a quasi-isomorphism. In particular, if M, N are A -modules and M is I -power torsion, then the canonical map

$$\text{Ext}_A^i(M, N) \longrightarrow \text{Ext}_B^i(M \otimes_A B, N \otimes_A B)$$

is an isomorphism for all i .

Proof. Let $Z = V(I) \subset \text{Spec}(A)$ and $Y = V(IB) \subset \text{Spec}(B)$. Since the cohomology modules of K are I power torsion, the canonical map $R\Gamma_Z(L) \rightarrow L$ induces an isomorphism

$$R\text{Hom}_A(K, R\Gamma_Z(L)) \rightarrow R\text{Hom}_A(K, L)$$

in $D(A)$. Similarly, the cohomology modules of $K \otimes_A B$ are IB power torsion and we have an isomorphism

$$R\text{Hom}_B(K \otimes_A B, R\Gamma_Y(L \otimes_A B)) \rightarrow R\text{Hom}_B(K \otimes_A B, L \otimes_A B)$$

in $D(B)$. By Lemma 43.8.11 we have $R\Gamma_Z(L) \otimes_A B = R\Gamma_Y(L \otimes_A B)$. Hence it suffices to show that the map

$$R\text{Hom}_A(K, R\Gamma_Z(L)) \rightarrow R\text{Hom}_B(K \otimes_A B, R\Gamma_Z(L) \otimes_A B)$$

is a quasi-isomorphism. This follows from Lemma 43.8.13. \square

43.9. Torsion versus complete modules

Let A be a ring and let I be a finitely generated ideal. In this case we can consider the derived category $D_{I^\infty\text{-torsion}}(A)$ of complexes with I -power torsion cohomology modules (Section 43.8) and the derived category $D_{\text{comp}}(A, I)$ of derived complete complexes (More on Algebra, Section 15.64). In this section we show these categories are equivalent. A more general statement can be found in [DG02].

Lemma 43.9.1. *Let A be a ring and let I be a finitely generated ideal. Let $R\Gamma_Z$ be as in Lemma 43.8.5. Let \wedge denote derived completion as in More on Algebra, Lemma 15.64.9. For an object K in $D(A)$ we have*

$$R\Gamma_Z(K^\wedge) = R\Gamma_Z(K) \quad \text{and} \quad (R\Gamma_Z(K))^\wedge = K^\wedge$$

in $D(A)$.

Proof. Choose $f_1, \dots, f_r \in A$ generating I . Recall that

$$K^\wedge = R\mathrm{Hom}\left(\left(A \rightarrow \prod A_{f_{i_0}} \rightarrow \prod A_{f_{i_0 i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}\right), K\right)$$

by More on Algebra, Lemma 15.64.9. Hence the cone $C = \mathrm{Cone}(K \rightarrow K^\wedge)$ is given by

$$R\mathrm{Hom}\left(\left(\prod A_{f_{i_0}} \rightarrow \prod A_{f_{i_0 i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}\right), K\right)$$

which can be represented by a complex endowed with a finite filtration whose successive quotients are isomorphic to

$$R\mathrm{Hom}(A_{f_{i_0} \dots f_{i_p}}, K), \quad p > 0$$

These complexes vanish on applying $R\Gamma_Z$, see Lemma 43.8.6. Applying $R\Gamma_Z$ to the distinguished triangle $K \rightarrow K^\wedge \rightarrow C \rightarrow K[1]$ we see that the first formula of the lemma is correct.

Recall that

$$R\Gamma_Z(K) = K \otimes^{\mathbf{L}} \left(A \rightarrow \prod A_{f_{i_0}} \rightarrow \prod A_{f_{i_0 i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r} \right)$$

by Lemma 43.8.5. Hence the cone $C = \mathrm{Cone}(R\Gamma_Z(K) \rightarrow K)$ can be represented by a complex endowed with a finite filtration whose successive quotients are isomorphic to

$$K \otimes_A A_{f_{i_0} \dots f_{i_p}}, \quad p > 0$$

These complexes vanish on applying \wedge , see More on Algebra, Lemma 15.64.10. Applying derived completion to the distinguished triangle $R\Gamma_Z(K) \rightarrow K \rightarrow C \rightarrow R\Gamma_Z(K)[1]$ we see that the second formula of the lemma is correct. \square

The following result is a special case of a very general phenomenon concerning admissible subcategories of a triangulated category.

Proposition 43.9.2. *Let A be a ring and let $I \subset A$ be a finitely generated ideal. The functors $R\Gamma_Z$ and \wedge define quasi-inverse equivalences of categories*

$$D_{I^\infty\text{-torsion}}(A) \leftrightarrow D_{\mathrm{comp}}(A, I)$$

Proof. Follows immediately from Lemma 43.9.1. \square

The following addendum of the proposition above makes the correspondence on morphisms more precise.

Lemma 43.9.3. *With notation as in Lemma 43.9.1. For objects K, L in $D(A)$ there is a canonical isomorphism*

$$R\mathrm{Hom}(K^\wedge, L^\wedge) \longrightarrow R\mathrm{Hom}(R\Gamma_Z(K), R\Gamma_Z(L))$$

in $D(A)$.

Proof. Say $I = (f_1, \dots, f_r)$. Denote $C = (A \rightarrow \prod A_{f_i} \rightarrow \dots \rightarrow A_{f_1 \dots f_r})$ the alternating Čech complex. Then derived completion is given by $R\mathrm{Hom}(C, -)$ and local cohomology by $C \otimes^{\mathbf{L}} -$. Combining the isomorphism

$$R\mathrm{Hom}(K \otimes^{\mathbf{L}} C, L \otimes^{\mathbf{L}} C) = R\mathrm{Hom}(K, R\mathrm{Hom}(C, L \otimes^{\mathbf{L}} C))$$

(More on Algebra, Lemma 15.55.1) and the map

$$L \rightarrow R\mathrm{Hom}(C, L \otimes^{\mathbf{L}} C)$$

(More on Algebra, Lemma 15.55.8) we obtain a map

$$\gamma : R\mathrm{Hom}(K, L) \rightarrow R\mathrm{Hom}(K \otimes^{\mathbf{L}} C, L \otimes^{\mathbf{L}} C)$$

On the other hand, the right hand side is derived complete as it is equal to

$$R\mathrm{Hom}(C, R\mathrm{Hom}(K, L \otimes^{\mathbf{L}} C)).$$

Thus γ factors through the derived completion of $R\mathrm{Hom}(K, L)$ by the universal property of derived completion. However, the derived completion goes inside the $R\mathrm{Hom}$ by More on Algebra, Lemma 15.64.11 and we obtain the desired map.

To show that the map of the lemma is an isomorphism we may assume that K and L are derived complete, i.e., $K = K^\wedge$ and $L = L^\wedge$. In this case we are looking at the map

$$\gamma : R\mathrm{Hom}(K, L) \longrightarrow R\mathrm{Hom}(R\Gamma_Z(K), R\Gamma_Z(L))$$

By Proposition 43.9.2 we know that the cohomology groups of the left and the right hand side coincide. In other words, we have to check that the map γ sends a morphism $\alpha : K \rightarrow L$ in $D(A)$ to the morphism $R\Gamma_Z(\alpha) : R\Gamma_Z(K) \rightarrow R\Gamma_Z(L)$. We omit the verification (hint: note that $R\Gamma_Z(\alpha)$ is just the map $\alpha \otimes \mathrm{id}_C : K \otimes^{\mathbf{L}} C \rightarrow L \otimes^{\mathbf{L}} C$ which is almost the same as the construction of the map in More on Algebra, Lemma 15.55.8). \square

43.10. Trivial duality for a ring map

Let $A \rightarrow B$ be a ring homomorphism. Consider the functor

$$\mathrm{Hom}(B, -) : \mathrm{Mod}_A \longrightarrow \mathrm{Mod}_B, \quad M \longmapsto \mathrm{Hom}_A(B, M)$$

This functor is left exact and has a derived extension $R\mathrm{Hom}(B, -) : D(A) \rightarrow D(B)$. Note that for every $K \in D(A)$ there is a canonical map $i_* R\mathrm{Hom}(B, K) \rightarrow K$ where $i_* : D(B) \rightarrow D(A)$ is the obvious functor.

Lemma 43.10.1. *With notation as above. The functor $R\mathrm{Hom}(B, -)$ is the right adjoint to the functor $i_* : D(B) \rightarrow D(A)$.*

Proof. This is a consequence of the fact that i_* and $\mathrm{Hom}_A(B, -)$ are adjoint functors by Algebra, Lemma 10.13.3. See Derived Categories, Lemma 13.28.4. \square

Lemma 43.10.2. *With notation as above. For K in $D(A)$ we have $R^q \mathrm{Hom}(B, K) = \mathrm{Ext}_A^q(B, K)$ as A -modules (the left hand side starts out as a B -module).*

Proof. Omitted. \square

Let A be a Noetherian ring. We will denote

$$D_{\mathrm{Coh}}(A) \subset D(A)$$

the full subcategory consisting of those objects K of $D(A)$ whose cohomology modules are all finite A -modules. This makes sense by Derived Categories, Section 13.13 because as A is Noetherian, the subcategory of finite A -modules is a Serre subcategory of Mod_A .

Lemma 43.10.3. *With notation as above, assume $A \rightarrow B$ is a finite ring map of Noetherian rings. Then $R\mathrm{Hom}(B, -)$ maps $D_{\mathrm{Coh}}^+(A)$ into $D_{\mathrm{Coh}}^+(B)$.*

Proof. We have to show: if $K \in D^+(A)$ has finite cohomology modules, then the complex $R\mathrm{Hom}(B, K)$ has finite cohomology modules too. This follows for example from Lemma 43.10.2 if we can show the ext modules $\mathrm{Ext}_A^i(B, K)$ are finite A -modules. Since K is bounded below there is a convergent spectral sequence

$$\mathrm{Ext}_A^p(B, H^q(K)) \Rightarrow \mathrm{Ext}_A^{p+q}(B, K)$$

This finishes the proof as the modules $\mathrm{Ext}_A^p(B, H^q(K))$ are finite by Algebra, Lemma 10.69.9. \square

Remark 43.10.4. Let A be a ring and let $I \subset A$ be an ideal. Set $B = A/I$. In this case the functor $\mathrm{Hom}_A(B, -)$ is equal to the functor

$$\mathrm{Mod}_A \longrightarrow \mathrm{Mod}_B, \quad M \longmapsto M[I]$$

which sends M to the submodule of I -torsion.

43.11. Sections with support in a closed subscheme

Let $i : (Z, \mathcal{O}_Z) \rightarrow (X, \mathcal{O}_X)$ be a morphism of ringed spaces such that i is a homeomorphism onto a closed subset and such that $i^\# : \mathcal{O}_X \rightarrow i_*\mathcal{O}_Z$ is surjective. (For example a closed immersion of schemes.) Let $\mathcal{I} = \mathrm{Ker}(i^\#)$. For a sheaf of \mathcal{O}_X -modules \mathcal{F} the sheaf

$$\mathcal{H}om_{\mathcal{O}_X}(i_*\mathcal{O}_Z, \mathcal{F})$$

is a sheaf of \mathcal{O}_X -modules annihilated by \mathcal{I} . Hence by Modules, Lemma 17.13.4 there is a sheaf of \mathcal{O}_Z -modules, which we will denote $\mathcal{H}om(\mathcal{O}_Z, \mathcal{F})$, such that

$$i_*\mathcal{H}om(\mathcal{O}_Z, \mathcal{F}) = \mathcal{H}om_{\mathcal{O}_X}(i_*\mathcal{O}_Z, \mathcal{F})$$

as \mathcal{O}_X -modules. We spell out what this means.

Lemma 43.11.1. *With notation as above. The functor $\mathcal{H}om(\mathcal{O}_Z, -)$ is a right adjoint to the functor $i_* : \mathrm{Mod}(\mathcal{O}_Z) \rightarrow \mathrm{Mod}(\mathcal{O}_X)$. For $V \subset Z$ open we have*

$$\Gamma(V, \mathcal{H}om(\mathcal{O}_Z, \mathcal{F})) = \{s \in \Gamma(U, \mathcal{F}) \mid \mathcal{I}s = 0\}$$

where $U \subset X$ is an open whose intersection with Z is V .

Proof. Let \mathcal{G} be a sheaf of \mathcal{O}_Z -modules. Then

$$\mathrm{Hom}_{\mathcal{O}_X}(i_*\mathcal{G}, \mathcal{F}) = \mathrm{Hom}_{i_*\mathcal{O}_Z}(i_*\mathcal{G}, \mathcal{H}om_{\mathcal{O}_X}(i_*\mathcal{O}_Z, \mathcal{F})) = \mathrm{Hom}_{\mathcal{O}_Z}(\mathcal{G}, \mathcal{H}om(\mathcal{O}_Z, \mathcal{F}))$$

The first equality by Modules, Lemma 17.19.5 and the second by the fully faithfulness of i_* , see Modules, Lemma 17.13.4. The description of sections is left to the reader. \square

The functor

$$\mathrm{Mod}(\mathcal{O}_X) \longrightarrow \mathrm{Mod}(\mathcal{O}_Z), \quad \mathcal{F} \longmapsto \mathcal{H}om(\mathcal{O}_Z, \mathcal{F})$$

is left exact and has a derived extension

$$R\mathcal{H}om(\mathcal{O}_Z, -) : D(\mathcal{O}_X) \rightarrow D(\mathcal{O}_Z).$$

Lemma 43.11.2. *With notation as above. The functor $R\mathcal{H}om(\mathcal{O}_Z, -)$ is the right adjoint of the functor $i_* : D(\mathcal{O}_Z) \rightarrow D(\mathcal{O}_X)$.*

Proof. This is a consequence of the fact that i_* and $\mathcal{H}om(\mathcal{O}_Z, -)$ are adjoint functors by Lemma 43.11.1. See Derived Categories, Lemma 13.28.4. \square

Lemma 43.11.3. *With notation as above. For any \mathcal{O}_X -module \mathcal{F} we have*

$$i_* R\mathcal{H}om(\mathcal{O}_Z, \mathcal{F}) = R\mathcal{H}om(i_* \mathcal{O}_Z, \mathcal{F})$$

in $D(\mathcal{O}_X)$.

Proof. Omitted. □

Lemma 43.11.4. *In the situation above, assume $i : Z \rightarrow X$ is a pseudo-coherent morphism of schemes (for example if X is locally Noetherian). Then*

- (1) $R\mathcal{H}om(\mathcal{O}_Z, -)$ maps $D_{QCoh}^+(\mathcal{O}_X)$ into $D_{QCoh}^+(\mathcal{O}_Z)$, and
- (2) if $X = \text{Spec}(A)$ and $Z = \text{Spec}(B)$, then the diagram

$$\begin{array}{ccc} D^+(B) & \longrightarrow & D_{QCoh}^+(\mathcal{O}_Z) \\ \uparrow R\mathcal{H}om(B, -) & & \uparrow R\mathcal{H}om(\mathcal{O}_Z, -) \\ D^+(A) & \longrightarrow & D_{QCoh}^+(\mathcal{O}_X) \end{array}$$

is commutative.

Proof. To explain the parenthetical remark, if X is locally Noetherian, then i is pseudo-coherent by More on Morphisms, Lemma 36.40.8.

Let K be an object of $D_{QCoh}^+(\mathcal{O}_X)$. To prove (1), by Morphisms, Lemma 28.4.1 it suffices to show that i_* applied to $H^n(R\mathcal{H}om(\mathcal{O}_Z, K))$ produces a quasi-coherent module on X . By Lemma 43.11.3 this means we have to show that $R\mathcal{H}om(i_* \mathcal{O}_Z, K)$ is in $D_{QCoh}(\mathcal{O}_X)$. Since i is pseudo-coherent the sheaf \mathcal{O}_Z is a pseudo-coherent \mathcal{O}_X -module. Hence the result follows from Derived Categories of Schemes, Lemma 35.9.8.

Assume $X = \text{Spec}(A)$ and $Z = \text{Spec}(B)$ as in (2). Let I^\bullet be a bounded below complex of injective A -modules representing an object K of $D^+(A)$. Then we know that $R\mathcal{H}om(B, K) = \text{Hom}_A(B, I^\bullet)$ viewed as a complex of B -modules. Choose a quasi-isomorphism

$$\tilde{I}^\bullet \rightarrow I^\bullet$$

where \tilde{I}^\bullet is a bounded below complex of injective \mathcal{O}_X -modules. It follows from the description of the functor $\mathcal{H}om(\mathcal{O}_Z, -)$ in Lemma 43.11.1 that there is a map

$$\text{Hom}_A(B, I^\bullet) \rightarrow \Gamma(Z, \mathcal{H}om(\mathcal{O}_Z, \tilde{I}^\bullet))$$

Observe that $\mathcal{H}om(\mathcal{O}_Z, \tilde{I}^\bullet)$ represents $R\mathcal{H}om(\mathcal{O}_Z, \tilde{K})$. Applying the universal property of the \sim functor we obtain a map

$$\widetilde{\text{Hom}_A(B, I^\bullet)} \rightarrow R\mathcal{H}om(\mathcal{O}_Z, \tilde{K})$$

in $D(\mathcal{O}_Z)$. We may check that this map is an isomorphism in $D(\mathcal{O}_Z)$ after applying i_* . However, once we apply i_* we obtain the isomorphism of Derived Categories of Schemes, Lemma 35.9.8 via the identification of Lemma 43.11.3. □

Lemma 43.11.5. *In this situation above. Assume X is a locally Noetherian scheme. Then $R\mathcal{H}om(\mathcal{O}_Z, -)$ maps $D_{Coh}^+(\mathcal{O}_X)$ into $D_{Coh}^+(\mathcal{O}_Z)$.*

Proof. The question is local on X , hence we may assume that X is affine. Say $X = \text{Spec}(A)$ and $Z = \text{Spec}(B)$ with A Noetherian and $A \rightarrow B$ surjective. In this case, we can apply Lemma 43.11.4 to translate the question into algebra. The corresponding algebra result is a consequence of Lemma 43.10.3. □

Lemma 43.11.6. *Let $i : D \rightarrow X$ be the inclusion of an effective Cartier divisor. Denote $\mathcal{N} = i^* \mathcal{O}_X(D)$ the normal sheaf of i (Morphisms, Section 28.33). Then for a finite locally free \mathcal{O}_X -module \mathcal{E} we have $R\mathcal{H}om(\mathcal{O}_D, \mathcal{E}) = i^* \mathcal{E} \otimes_{\mathcal{O}_D} \mathcal{N}[-1]$.*

Proof. Omitted. This lemma can be significantly generalized. □

43.12. Dualizing complexes

In this section we define dualizing complexes for Noetherian rings.

Definition 43.12.1. Let A be a Noetherian ring. A *dualizing complex* is a complex of A -modules ω_A^\bullet such that

- (1) ω_A^\bullet has finite injective dimension,
- (2) $H^i(\omega_A^\bullet)$ is a finite A -module for all i , and
- (3) $A \rightarrow R\mathcal{H}om(\omega_A^\bullet, \omega_A^\bullet)$ is a quasi-isomorphism.

This definition takes some time getting used to. It is perhaps a good idea to prove some of the following lemmas yourself without reading the proofs.

Lemma 43.12.2. *Let A be a Noetherian ring. If ω_A^\bullet is a dualizing complex, then the functor*

$$D : K \mapsto R\mathcal{H}om(K, \omega_A^\bullet)$$

is an anti-equivalence $D_{Coh}(A) \rightarrow D_{Coh}(A)$ which exchanges $D_{Coh}^+(A)$ and $D_{Coh}^-(A)$ and induces an equivalence $D_{Coh}^b(A) \rightarrow D_{Coh}^b(A)$. Moreover $D \circ D$ is isomorphic to the identity functor.

Proof. Let K be an object of $D_{Coh}(A)$. Pick an integer n and consider the distinguished triangle

$$\tau_{\leq n} K \rightarrow K \rightarrow \tau_{\geq n+1} K \rightarrow \tau_{\leq n} K[1]$$

see Derived Categories, Remark 13.12.4. Since ω_A^\bullet has finite injective dimension we see that $R\mathcal{H}om(\tau_{\geq n+1} K, \omega_A^\bullet)$ has vanishing cohomology in degrees $\geq n - c$ for some constant c . On the other hand, we obtain a spectral sequence

$$\text{Ext}_A^p(H^{-q}(\tau_{\leq n} K, \omega_A^\bullet)) \Rightarrow \text{Ext}_A^{p+q}(\tau_{\leq n} K, \omega_A^\bullet) = H^{p+q}(R\mathcal{H}om(\tau_{\leq n} K, \omega_A^\bullet))$$

which shows that these cohomology modules are finite. Since for $n > p + q + c$ this is equal to $H^{p+q}(R\mathcal{H}om(K, \omega_A^\bullet))$ we see that $R\mathcal{H}om(K, \omega_A^\bullet)$ is indeed an object of $D_{Coh}(A)$. By More on Algebra, Lemma 15.55.6 and the assumptions on the dualizing complex we obtain a canonical isomorphism

$$K = R\mathcal{H}om(\omega_A^\bullet, \omega_A^\bullet) \otimes_A^L K \longrightarrow R\mathcal{H}om(R\mathcal{H}om(K, \omega_A^\bullet), \omega_A^\bullet)$$

Thus our functor has a quasi-inverse and the proof is complete. □

Lemma 43.12.3. *Let A be a Noetherian ring. Let $K \in D_{Coh}^b(A)$. Let \mathfrak{m} be a maximal ideal of A . If $H^i(K)/\mathfrak{m}H^i(K) \neq 0$, then there exists a finite A -module E annihilated by a power of \mathfrak{m} and a map $K \rightarrow E[-i]$ which is nonzero on $H^i(K)$.*

Proof. Let I be the injective hull of the residue field of \mathfrak{m} . If $H^i(K)/\mathfrak{m}H^i(K) \neq 0$, then there exists a nonzero map $H^i(K) \rightarrow I$. Since I is injective, we can lift this to a nonzero map $K \rightarrow I[-i]$. Recall that $I = \bigcup I[\mathfrak{m}^n]$, see Lemma 43.7.2 and that each of the modules $E = I[\mathfrak{m}^n]$ is of the desired type. Thus it suffices to prove that

$$\text{Hom}_{D(A)}(K, I) = \text{colim } \text{Hom}_{D(A)}(K, I[\mathfrak{m}^n])$$

This would be immediate if K were a compact object (or a perfect object) of $D(A)$. This is not the case, but K is a pseudo-coherent object which is enough here. Namely, we can represent K by a bounded above complex of finite free R -modules K^\bullet . In this case the Hom groups above are computed by using $\text{Hom}_{K(A)}(K^\bullet, -)$. As each K^n is finite free the limit statement holds and the proof is complete. \square

Let R be a ring. We will say that an object L of $D(R)$ is *invertible* if there is an open covering $\text{Spec}(R) = \bigcup D(f_i)$ such that $L \otimes_R R_{f_i} \cong R_{f_i}[-n_i]$ for some integers n_i . In this case, the function

$$\mathfrak{p} \mapsto n_{\mathfrak{p}}, \quad \text{where } n_{\mathfrak{p}} \text{ is the unique integer such that } H^{n_{\mathfrak{p}}}(L \otimes \kappa(\mathfrak{p})) \neq 0$$

is locally constant on $\text{Spec}(R)$. In particular, it follows that $L = \bigoplus H^n(L)[-n]$ which gives a well defined complex of R -modules (with zero differentials) representing L . Since each $H^n(L)$ is finite projective and nonzero for only a finite number of n we also see that L is a perfect object of $D(R)$.

Lemma 43.12.4. *Let A be a Noetherian ring. Let $F : D_{\text{Coh}}^b(A) \rightarrow D_{\text{Coh}}^b(A)$ be an A -linear equivalence of categories. Then $F(A)$ is an invertible object of $D(A)$.*

Proof. Let $\mathfrak{m} \subset A$ be a maximal ideal with residue field κ . Consider the object $F(\kappa)$. Since $\kappa = \text{Hom}_{D(A)}(\kappa, \kappa)$ we find that all cohomology groups of $F(\kappa)$ are annihilated by \mathfrak{m} . We also see that

$$\text{Ext}_A^i(\kappa, \kappa) = \text{Ext}_A^i(F(\kappa), F(\kappa)) = \text{Hom}_{D(A)}(F(\kappa), F(\kappa)[-i])$$

is zero for $i < 0$. Say $H^a(F(\kappa)) \neq 0$ and $H^b(F(\kappa)) \neq 0$ with a minimal and b maximal (so in particular $a \leq b$). Then there is a nonzero map

$$F(\kappa) \rightarrow H^b(F(\kappa))[-b] \rightarrow H^a(F(\kappa))[-b] \rightarrow F(\kappa)[a-b]$$

in $D(A)$ (nonzero because it induces a nonzero map on cohomology). This proves that $b = a$. We conclude that $F(\kappa) = \kappa[-a]$.

Let G be a quasi-inverse to our functor F . Arguing as above we find an integer b such that $G(\kappa) = \kappa[-b]$. On composing we find $a + b = 0$. Let E be a finite A -module which is annihilated by a power of \mathfrak{m} . Arguing by induction on the length of E we find that $G(E) = E'[-b]$ for some finite A -module E' annihilated by a power of \mathfrak{m} . Then $E[-a] = F(E')$. Next, we consider the groups

$$\text{Ext}_A^i(A, E') = \text{Ext}_A^i(F(A), F(E')) = \text{Hom}_{D(A)}(F(A), E[-a+i])$$

The left hand side is nonzero if and only if $i = 0$ and then we get E' . Applying this with $E = E' = \kappa$ and using Nakayama's lemma this implies that $H^j(F(A))$ is zero for $j > a$ and generated by 1 element for $j = a$. On the other hand, if $H^j(F(A))_{\mathfrak{m}}$ is not zero for some $j < a$, then there is a map $F(A) \rightarrow E[-a+i]$ for some $i < 0$ and some E (Lemma 43.12.3) Thus we see that $F(A)_{\mathfrak{m}} = M[-a]$ for some $A_{\mathfrak{m}}$ -module M generated by 1 element. However, since

$$A_{\mathfrak{m}} = \text{Hom}_{D(A)}(A, A)_{\mathfrak{m}} = \text{Hom}_{D(A)}(F(A), F(A))_{\mathfrak{m}} = \text{Hom}_{A_{\mathfrak{m}}}(M, M)$$

we see that $M \cong A_{\mathfrak{m}}$. We conclude that there exists an element $f \in A$, $f \notin \mathfrak{m}$ such that $F(A)_f$ is isomorphic to $A_f[-a]$. This finishes the proof. \square

Lemma 43.12.5. *Let A be a Noetherian ring. If ω_A^\bullet and $(\omega'_A)^\bullet$ are dualizing complexes, then $(\omega'_A)^\bullet$ is quasi-isomorphic to $\omega_A^\bullet \otimes_A^L L$ for some invertible object L of $D(A)$.*

Proof. By Lemmas 43.12.2 and 43.12.4 the functor $K \mapsto R\text{Hom}(R\text{Hom}(K, \omega_A^\bullet), (\omega'_A)^\bullet)$ maps A to an invertible object L . In other words, there is an isomorphism

$$L \longrightarrow R\text{Hom}(\omega_A^\bullet, (\omega'_A)^\bullet)$$

Since L has finite tor dimension, this means that we can apply More on Algebra, Lemma 15.55.6 to see that

$$R\text{Hom}(\omega_A^\bullet, (\omega'_A)^\bullet) \otimes_A^L K \longrightarrow R\text{Hom}(R\text{Hom}(K, \omega_A^\bullet), (\omega'_A)^\bullet)$$

is an isomorphism for K in $D_{\text{Coh}}^b(A)$. In particular, setting $K = \omega_A^\bullet$ finishes the proof. \square

Lemma 43.12.6. *Let A be a Noetherian ring. Let $B = S^{-1}A$ be a localization. If ω_A^\bullet is a dualizing complex, then $\omega_A^\bullet \otimes_A B$ is a dualizing complex for B .*

Proof. Let $\omega_A^\bullet \rightarrow I^\bullet$ be a quasi-isomorphism with I^\bullet a bounded complex of injectives. Then $S^{-1}I^\bullet$ is a bounded complex of injective $B = S^{-1}A$ -modules (Lemma 43.3.9) representing $\omega_A^\bullet \otimes_A B$. Thus $\omega_A^\bullet \otimes_A B$ has finite injective dimension. Since $H^i(\omega_A^\bullet \otimes_A B) = H^i(\omega_A^\bullet) \otimes_A B$ by flatness of $A \rightarrow B$ we see that $\omega_A^\bullet \otimes_A B$ has finite cohomology modules. Finally, the map

$$B \longrightarrow R\text{Hom}(\omega_A^\bullet \otimes_A B, \omega_A^\bullet \otimes_A B)$$

is a quasi-isomorphism as formation of internal hom commutes with flat base change in this case, see More on Algebra, Lemma 15.55.7. \square

Lemma 43.12.7. *Let A be a Noetherian ring. Let $f_1, \dots, f_n \in A$ generate the unit ideal. If ω_A^\bullet is a complex of A -modules such that $(\omega_A^\bullet)_{f_i}$ is a dualizing complex for A_{f_i} for all i , then ω_A^\bullet is a dualizing complex for A .*

Proof. Consider the double complex

$$\prod_{i_0} (\omega_A^\bullet)_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} (\omega_A^\bullet)_{f_{i_0} f_{i_1}} \rightarrow \dots$$

The associated total complex is quasi-isomorphic to ω_A^\bullet for example by Descent, Remark 34.3.10 or by Derived Categories of Schemes, Lemma 35.8.4. By assumption the complexes $(\omega_A^\bullet)_{f_i}$ have finite injective dimension as complexes of A_{f_i} -modules. This implies that each of the complexes $(\omega_A^\bullet)_{f_{i_0} \dots f_{i_p}}$, $p > 0$ has finite injective dimension over $A_{f_{i_0} \dots f_{i_p}}$, see Lemma 43.3.9. This in turn implies that each of the complexes $(\omega_A^\bullet)_{f_{i_0} \dots f_{i_p}}$, $p > 0$ has finite injective dimension over A , see Lemma 43.3.2. Hence ω_A^\bullet has finite injective dimension as a complex of A -modules (as it can be represented by a complex endowed with a finite filtration whose graded parts have finite injective dimension). Since $H^n(\omega_A^\bullet)_{f_i}$ is a finite A_{f_i} module for each i we see that $H^i(\omega_A^\bullet)$ is a finite A -module, see Algebra, Lemma 10.23.2. Finally, the (derived) base change of the map $A \rightarrow R\text{Hom}(\omega_A^\bullet, \omega_A^\bullet)$ to A_{f_i} is the map $A_{f_i} \rightarrow R\text{Hom}((\omega_A^\bullet)_{f_i}, (\omega_A^\bullet)_{f_i})$ by More on Algebra, Lemma 15.55.7. Hence we deduce that $A \rightarrow R\text{Hom}(\omega_A^\bullet, \omega_A^\bullet)$ is an isomorphism and the proof is complete. \square

Lemma 43.12.8. *Let $A \rightarrow B$ be a surjective homomorphism of Noetherian rings. Let ω_A^\bullet be a dualizing complex. Then $R\text{Hom}(B, \omega_A^\bullet)$ is a dualizing complex for B .*

Proof. Let $\omega_A^\bullet \rightarrow I^\bullet$ be a quasi-isomorphism with I^\bullet a bounded complex of injectives. Then $\text{Hom}_A(B, I^\bullet)$ is a bounded complex of injective B -modules (Lemma

43.3.4) representing $R\mathrm{Hom}(B, \omega_A^\bullet)$. Thus $R\mathrm{Hom}(B, \omega_A^\bullet)$ has finite injective dimension. By Lemma 43.10.3 it is an object of $D_{\mathrm{Coh}}(B)$. Finally, we compute

$$\mathrm{Hom}_{D(B)}(R\mathrm{Hom}(B, \omega_A^\bullet), R\mathrm{Hom}(B, \omega_A^\bullet)) = \mathrm{Hom}_{D(A)}(R\mathrm{Hom}(B, \omega_A^\bullet), \omega_A^\bullet) = B$$

and for $n \neq 0$ we compute

$$\mathrm{Hom}_{D(B)}(R\mathrm{Hom}(B, \omega_A^\bullet), R\mathrm{Hom}(B, \omega_A^\bullet)[n]) = \mathrm{Hom}_{D(A)}(R\mathrm{Hom}(B, \omega_A^\bullet), \omega_A^\bullet[n]) = 0$$

which proves the last property of a dualizing complex. In the displayed equations, the first equality holds by Lemma 43.10.1 and the second equality holds by Lemma 43.12.2. \square

Lemma 43.12.9. *Let A be a Noetherian ring. If ω_A^\bullet is a dualizing complex, then $\omega_A^\bullet \otimes_A A[x]$ is a dualizing complex for $A[x]$.*

Proof. Set $B = A[x]$ and $\omega_B^\bullet = \omega_A^\bullet \otimes_A B$. It follows from Lemma 43.3.11 and More on Algebra, Lemma 15.53.4 that ω_B^\bullet has finite injective dimension. Since $H^i(\omega_B^\bullet) = H^i(\omega_A^\bullet) \otimes_A B$ by flatness of $A \rightarrow B$ we see that $\omega_A^\bullet \otimes_A B$ has finite cohomology modules. Finally, the map

$$B \longrightarrow R\mathrm{Hom}(\omega_B^\bullet, \omega_B^\bullet)$$

is a quasi-isomorphism as formation of internal hom commutes with flat base change in this case, see More on Algebra, Lemma 15.55.7. \square

Proposition 43.12.10. *Let A be a Noetherian ring which has a dualizing complex. Then any A -algebra essentially of finite type over A has a dualizing complex.*

Proof. This follows from a combination of Lemmas 43.12.6, 43.12.8, and 43.12.9. \square

Lemma 43.12.11. *Let A be a Noetherian ring. Let ω_A^\bullet be a dualizing complex. Let $\mathfrak{m} \subset A$ be a maximal ideal and set $\kappa = A/\mathfrak{m}$. Then $R\mathrm{Hom}_A(\kappa, \omega_A^\bullet) \cong \kappa[n]$ for some $n \in \mathbf{Z}$.*

Proof. This is true because $R\mathrm{Hom}_A(\kappa, \omega_A^\bullet)$ is a dualizing complex over κ (Lemma 43.12.8), because dualizing complexes over κ are unique up to shifts (Lemma 43.12.5), and because κ is a dualizing complex over κ . \square

43.13. Dualizing complexes over local rings

In this section $(A, \mathfrak{m}, \kappa)$ will be a Noetherian local ring endowed with a dualizing complex ω_A^\bullet such that the integer n of Lemma 43.12.11 is zero. More precisely, we assume that $R\mathrm{Hom}_A(\kappa, \omega_A^\bullet) = \kappa[0]$. In this case we will say that the dualizing complex is *normalized*. Observe that a normalized dualizing complex is unique up to isomorphism and that any other dualizing complex for A is isomorphic to a shift of a normalized one (Lemma 43.12.5).

Lemma 43.13.1. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex ω_A^\bullet . Let $A \rightarrow B$ be surjective. Then $\omega_B^\bullet = R\mathrm{Hom}_A(B, \omega_A^\bullet)$ is a normalized dualizing complex for B .*

Proof. By Lemma 43.12.8 the complex ω_B^\bullet is dualizing for B . We compute

$$R\mathrm{Hom}_B(\kappa, R\mathrm{Hom}_A(B, \omega_A^\bullet)) = R\mathrm{Hom}_A(\kappa, \omega_A^\bullet) \cong \kappa[0]$$

The first equality by Lemma 43.10.1. \square

Lemma 43.13.2. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let F be an A -linear self-equivalence of the category of finite length A -modules. Then F is isomorphic to the identity functor.*

Proof. Since κ is the unique simple object of the category we have $F(\kappa) \cong \kappa$. Since our category is abelian, we find that F is exact. Hence $F(E)$ has the same length as E for all finite length modules E . Since $\text{Hom}(E, \kappa) = \text{Hom}(F(E), F(\kappa)) \cong \text{Hom}(F(E), \kappa)$ we conclude from Nakayama's lemma that E and $F(E)$ have the same number of generators. Hence $F(A/\mathfrak{m}^n)$ is a cyclic A -module. Pick a generator $e \in F(A/\mathfrak{m}^n)$. Since F is A -linear we conclude that $\mathfrak{m}^n e = 0$. The map $A/\mathfrak{m}^n \rightarrow F(A/\mathfrak{m}^n)$ has to be an isomorphism as the lengths are equal. Pick an element

$$e \in \lim F(A/\mathfrak{m}^n)$$

which maps to a generator for all n (small argument omitted). Then we obtain a system of isomorphisms $A/\mathfrak{m}^n \rightarrow F(A/\mathfrak{m}^n)$ compatible with all A -module maps $A/\mathfrak{m}^n \rightarrow A/\mathfrak{m}^{n'}$ (by A -linearity of F again). Since any finite length module is a cokernel of a map between direct sums of cyclic modules, we obtain the isomorphism of the lemma. \square

Lemma 43.13.3. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex ω_A^\bullet . Let E be an injective hull of κ . Then there exists a functorial isomorphism*

$$R\text{Hom}(N, \omega_A^\bullet) = \text{Hom}_A(N, E)[0]$$

for N running through the finite length A -modules.

Proof. By induction on the length of N we see that $R\text{Hom}(N, \omega_A^\bullet)$ is a module of finite length sitting in degree 0. Thus $R\text{Hom}_A(-, \omega_A^\bullet)$ induces an anti-equivalence on the category of finite length modules. Since the same is true for $\text{Hom}_A(-, E)$ by Proposition 43.7.8 we see that

$$N \longmapsto \text{Hom}_A(R\text{Hom}(N, \omega_A^\bullet), E)$$

is an equivalence as in Lemma 43.13.2. Hence it is isomorphic to the identity functor. Since $\text{Hom}_A(-, E)$ applied twice is the identity (Proposition 43.7.8) we obtain the statement of the lemma. \square

Lemma 43.13.4. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex ω_A^\bullet . If $\dim(A) = 0$, then $\omega_A^\bullet \cong E[0]$ where E is an injective hull of the residue field.*

Proof. Immediate from Lemma 43.13.3. \square

Lemma 43.13.5. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex. Let $I \subset \mathfrak{m}$ be an ideal of finite length. Set $B = A/I$. Then there is a distinguished triangle*

$$\omega_B^\bullet \rightarrow \omega_A^\bullet \rightarrow \text{Hom}_A(I, E)[0] \rightarrow \omega_B^\bullet[1]$$

in $D(A)$ where E is an injective hull of κ and ω_B^\bullet is a normalized dualizing complex for B .

Proof. Use the short exact sequence $0 \rightarrow I \rightarrow A \rightarrow B \rightarrow 0$ and Lemmas 43.13.3 and 43.13.1. \square

Lemma 43.13.6. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex ω_A^\bullet . Let $f \in \mathfrak{m}$ be a nonzerodivisor. Set $B = A/(f)$. Then there is a distinguished triangle*

$$\omega_B^\bullet \rightarrow \omega_A^\bullet \rightarrow \omega_A^\bullet \rightarrow \omega_B^\bullet[1]$$

in $D(A)$ where ω_B^\bullet is a normalized dualizing complex for B .

Proof. Use the short exact sequence $0 \rightarrow A \rightarrow A \rightarrow B \rightarrow 0$ and Lemma 43.13.1. \square

Lemma 43.13.7. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex ω_A^\bullet . Let $d = \dim(A)$. Then*

- (1) *if $H^i(\omega_A^\bullet)$ is nonzero, then $i \in \{-d, \dots, 0\}$,*
- (2) *the dimension of the support of $H^i(\omega_A^\bullet)$ is at most $-i$,*

Proof. We prove this by induction on the dimension of A . If $\dim(A) = 0$ this follows immediately from Lemma 43.13.4.

Assume that the result holds for rings of dimension $< d$ and that A has depth at least 1. Then we can find a nonzero divisor f and apply Lemma 43.13.6 and the induction hypothesis to B . It follows that multiplication by f is surjective on $H^i(\omega_A^\bullet)$ for $i > 0$ and $i < d$. By Nakayama we conclude these cohomology modules are zero, i.e., (1) holds. If the dimension of the support of $H^i(\omega_A^\bullet)$ is e , then the dimension of the support of $H^i(\omega_A^\bullet)/fH^i(\omega_A^\bullet) \subset H^{i+1}(\omega_B^\bullet)$ is at least $e - 1$. Hence our induction assumption gives that $e \leq -i$.

If A has depth 0, then we let $I = A[\mathfrak{m}^\infty]$ be the maximal ideal of A having finite length. Then $B = A/I$ has depth ≥ 1 so we know the result for B . Applying Lemma 43.13.5 we obtain the result for A . \square

Lemma 43.13.8. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with normalized dualizing complex ω_A^\bullet . Let \mathfrak{p} be a minimal prime of A with $\dim(A/\mathfrak{p}) = e$. Then $H^i(\omega_A^\bullet)_{\mathfrak{p}}$ is nonzero if and only if $i = -e$.*

Proof. Since $A_{\mathfrak{p}}$ has dimension zero, there exists an integer $n > 0$ such that $\mathfrak{p}^n A_{\mathfrak{p}}$ is zero. Set $B = A/\mathfrak{p}^n$ and $\omega_B^\bullet = R\mathrm{Hom}_A(B, \omega_A^\bullet)$. Since $B_{\mathfrak{p}} = A_{\mathfrak{p}}$ we see that $(\omega_B^\bullet)_{\mathfrak{p}} \cong (\omega_A^\bullet)_{\mathfrak{p}}$ by using More on Algebra, Lemma 15.55.7. By Lemma 43.13.1 we may replace A by B . After doing so, we see that $\dim(A) = e$. Then we see that $H^i(\omega_A^\bullet)_{\mathfrak{p}}$ can only be nonzero if $i = -e$ by Lemma 43.13.7. On the other hand, since $(\omega_A^\bullet)_{\mathfrak{p}}$ is a dualizing complex for the nonzero ring $A_{\mathfrak{p}}$ (Lemma 43.12.6) we see that the remaining module has to be nonzero. \square

43.14. The dimension function of a dualizing complex

Our results in the local setting have the following consequence: a Noetherian ring with has a dualizing complex is a universally catenary ring of finite dimension.

Lemma 43.14.1. *Let A be a Noetherian ring. Let \mathfrak{p} be a minimal prime of A . Then $H^i(\omega_A^\bullet)_{\mathfrak{p}}$ is nonzero for exactly one i .*

Proof. The complex $\omega_A^\bullet \otimes_A A_{\mathfrak{p}}$ is a dualizing complex for $A_{\mathfrak{p}}$ (Lemma 43.12.6). The dimension of $A_{\mathfrak{p}}$ is zero as \mathfrak{p} is minimal. Hence the result follows from Lemma 43.13.4. \square

Let A be a Noetherian ring and let ω_A^\bullet be a dualizing complex. Lemma 43.12.11 allows us to define a function

$$\delta = \delta_{\omega_A^\bullet} : \text{Spec}(A) \longrightarrow \mathbf{Z}$$

by mapping \mathfrak{p} to the integer of Lemma 43.12.11 for the dualizing complex $(\omega_A^\bullet)_{\mathfrak{p}}$ over $A_{\mathfrak{p}}$ (Lemma 43.12.6) and the residue field $\kappa(\mathfrak{p})$. To be precise, we define $\delta(\mathfrak{p})$ to be the unique integer such that

$$(\omega_A^\bullet)_{\mathfrak{p}}[-\delta(\mathfrak{p})]$$

is a normalized dualizing complex over the Noetherian local ring $A_{\mathfrak{p}}$.

Lemma 43.14.2. *Let A be a Noetherian ring and let ω_A^\bullet be a dualizing complex. Let $A \rightarrow B$ be a surjective ring map and let $\omega_B^\bullet = R\text{Hom}(B, \omega_A^\bullet)$ be the dualizing complex for B of Lemma 43.12.8. Then we have*

$$\delta_{\omega_B^\bullet} = \delta_{\omega_A^\bullet}|_{\text{Spec}(B)}$$

Proof. This follows from the definition of the functions and Lemma 43.13.1. \square

Lemma 43.14.3. *Let A be a Noetherian ring and let ω_A^\bullet be a dualizing complex. The function $\delta = \delta_{\omega_A^\bullet}$ defined above is a dimension function (Topology, Definition 5.19.1).*

Proof. Let $\mathfrak{p} \subset \mathfrak{q}$ be an immediate specialization. We have to show that $\delta(\mathfrak{p}) = \delta(\mathfrak{q}) + 1$. We may replace A by A/\mathfrak{p} , the complex ω_A^\bullet by $\omega_{A/\mathfrak{p}}^\bullet = R\text{Hom}(A/\mathfrak{p}, \omega_A^\bullet)$, the prime \mathfrak{p} by (0) , and the prime \mathfrak{q} by $\mathfrak{q}/\mathfrak{p}$, see Lemma 43.14.2. Thus we may assume that A is a domain, $\mathfrak{p} = (0)$, and \mathfrak{q} is a prime ideal of height 1.

Then $H^i(\omega_A^\bullet)_{(0)}$ is nonzero for exactly one i , say i_0 , by Lemma 43.14.1. In fact $i_0 = -\delta((0))$ because $(\omega_A^\bullet)_{(0)}[-\delta((0))]$ is a normalized dualizing complex over the field $A_{(0)}$.

On the other hand $(\omega_A^\bullet)_{\mathfrak{q}}[-\delta(\mathfrak{q})]$ is a normalized dualizing complex for $A_{\mathfrak{q}}$. By Lemma 43.13.8 we see that

$$H^e((\omega_A^\bullet)_{\mathfrak{q}}[-\delta(\mathfrak{q})])_{(0)} = H^{e-\delta(\mathfrak{q})}(\omega_A^\bullet)_{(0)}$$

is nonzero only for $e = -\dim(A_{\mathfrak{q}}) = -1$. We conclude

$$-\delta((0)) = -1 - \delta(\mathfrak{p})$$

as desired. \square

Lemma 43.14.4. *Let A be a Noetherian ring which has a dualizing complex. Then A is universally catenary of finite dimension.*

Proof. Because $\text{Spec}(A)$ has a dimension function by Lemma 43.14.3 it is catenary, see Topology, Lemma 5.19.2. Hence A is catenary, see Algebra, Lemma 10.101.2. It follows from Proposition 43.12.10 that A is universally catenary.

Because any dualizing complex ω_A^\bullet is in $D_{\text{Coh}}^b(A)$ the values of the function $\delta_{\omega_A^\bullet}$ in minimal primes are bounded by Lemma 43.14.1. On the other hand, for a maximal ideal \mathfrak{m} with residue field κ the integer $i = -\delta(\mathfrak{m})$ is the unique integer such that $\text{Ext}_A^i(\kappa, \omega_A^\bullet)$ is nonzero (Lemma 43.12.11). Since ω_A^\bullet has finite injective dimension these values are bounded too. Since the dimension of A is the maximal value of $\delta(\mathfrak{p}) - \delta(\mathfrak{m})$ where $\mathfrak{p} \subset \mathfrak{m}$ are a pair consisting of a minimal prime and a maximal prime we find that the dimension of $\text{Spec}(A)$ is bounded. \square

43.15. The local duality theorem

The main result in this section is due to Grothendieck.

Lemma 43.15.1. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let ω_A^\bullet be a normalized dualizing complex. Let $Z = V(\mathfrak{m}) \subset \text{Spec}(A)$. Then $E = R^0\Gamma_Z(\omega_A^\bullet)$ is an injective hull of κ and $R\Gamma_Z(\omega_A^\bullet) = E[0]$.*

Proof. By Lemma 43.8.9 we have $R\Gamma_{\mathfrak{m}} = R\Gamma_Z$. Thus

$$R\Gamma_Z(\omega_A^\bullet) = R\Gamma_{\mathfrak{m}}(\omega_A^\bullet) = \text{hocolim } R\text{Hom}(A/\mathfrak{m}^n, \omega_A^\bullet)$$

by Lemma 43.8.2. Let E' be an injective hull of the residue field. By Lemma 43.13.3 we can find isomorphisms

$$R\text{Hom}(A/\mathfrak{m}^n, \omega_A^\bullet) \cong \text{Hom}_A(A/I^n, E')[0]$$

compatible with transition maps. Since $E' = \bigcup E'[\mathfrak{m}^n] = \text{colim } \text{Hom}_A(A/I^n, E')$ by Lemma 43.7.3 we conclude that $E \cong E'$ and that all other cohomology groups of the complex $R\Gamma_Z(\omega_A^\bullet)$ are zero. \square

Remark 43.15.2. Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring with a normalized dualizing complex ω_A^\bullet . By Lemma 43.15.1 above we see that $R\Gamma_Z(\omega_A^\bullet)$ is an injective hull of the residue field placed in degree 0. In fact, this gives a “construction” or “realization” of the injective hull which is slightly more canonical than just picking any old injective hull. Namely, a normalized dualizing complex is unique up to isomorphism, with group of automorphisms the group of units of A , whereas an injective hull of κ is unique up to isomorphism, with group of automorphisms the group of units of the completion A^\wedge of A with respect to \mathfrak{m} .

Here is the main result of this section.

Theorem 43.15.3. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let ω_A^\bullet be a normalized dualizing complex. Let E be an injective hull of the residue field. Let $Z = V(\mathfrak{m}) \subset \text{Spec}(A)$. Denote $^\wedge$ derived completion with respect to \mathfrak{m} . Then*

$$R\text{Hom}(K, \omega_A^\bullet)^\wedge \cong R\text{Hom}(R\Gamma_Z(K), E[0])$$

for K in $D(A)$.

Proof. Observe that $E[0] \cong R\Gamma_Z(\omega_A^\bullet)$ by Lemma 43.15.1. By More on Algebra, Lemma 15.64.11 completion on the left hand side goes inside. Thus we have to prove

$$R\text{Hom}(K^\wedge, (\omega_A^\bullet)^\wedge) = R\text{Hom}(R\Gamma_Z(K), R\Gamma_Z(\omega_A^\bullet))$$

This follows from the equivalence between $D_{\text{comp}}(A, \mathfrak{m})$ and $D_{\mathfrak{m}^\infty\text{-torsion}}(A)$ given in Proposition 43.9.2. More precisely, it is a special case of Lemma 43.9.3. \square

Here is a special case of the theorem above.

Lemma 43.15.4. *Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian local ring. Let ω_A^\bullet be a normalized dualizing complex. Let E be an injective hull of the residue field. Let $K \in D_{\text{Coh}}(A)$. Then*

$$\text{Ext}_A^i(K, \omega_A^\bullet)^\wedge = \text{Hom}_A(H_{\mathfrak{m}}^i(K), E)$$

where $^\wedge$ denotes \mathfrak{m} -adic completion.

Proof. By Lemma 43.12.2 we see that $R\text{Hom}(K, \omega_A^\bullet)$ is an object of $D_{\text{Coh}}(A)$. It follows that the cohomology modules of the derived completion of $R\text{Hom}(K, \omega_A^\bullet)$ are equal to the usual completions $\text{Ext}_A^i(K, \omega_A^\bullet)^\wedge$ by More on Algebra, Lemma 15.64.20. On the other hand, we have $R\Gamma_{\mathfrak{m}} = R\Gamma_Z$ for $Z = V(\mathfrak{m})$ by Lemma 43.8.9. Moreover, the functor $\text{Hom}_A(-, E)$ is exact hence factors through cohomology. Hence the lemma is consequence of Theorem 43.15.3. \square

43.16. Dualizing complexes on schemes

We define a dualizing complex on a locally Noetherian scheme to be a complex which affine locally comes from a dualizing complex on the corresponding ring. This is not completely standard but agrees with all definitions in the literature on Noetherian schemes of finite dimension.

Lemma 43.16.1. *Let X be a locally Noetherian scheme. Let K be an object of $D(\mathcal{O}_X)$. The following are equivalent*

- (1) *For every affine open $U = \text{Spec}(A) \subset X$ there exists a dualizing complex ω_A^\bullet for A such that $K|_U$ is isomorphic to the image of ω_A^\bullet by the functor $\widetilde{}: D(A) \rightarrow D(\mathcal{O}_U)$.*
- (2) *There is an affine open covering $X = \bigcup U_i$, $U_i = \text{Spec}(A_i)$ such that for each i there exists a dualizing complex ω_i^\bullet for A_i such that $K|_{U_i}$ is isomorphic to the image of ω_i^\bullet by the functor $\widetilde{}: D(A_i) \rightarrow D(\mathcal{O}_{U_i})$.*

Proof. Assume (2) and let $U = \text{Spec}(A)$ be an affine open of X . Since condition (2) implies that K is in $D_{\text{QCoh}}(\mathcal{O}_X)$ we find an object ω_A^\bullet in $D(A)$ whose associated complex of quasi-coherent sheaves is isomorphic to $K|_U$, see Derived Categories of Schemes, Lemma 35.3.4. We will show that ω_A^\bullet is a dualizing complex for A which will finish the proof.

Since $X = \bigcup U_i$ is an open covering, we can find a standard open covering $U = D(f_1) \cup \dots \cup D(f_m)$ such that each $D(f_j)$ is a standard open in one of the affine opens U_i , see Schemes, Lemma 25.11.5. Say $D(f_j) = D(g_j)$ for $g_j \in A_{i_j}$. Then $A_{f_j} \cong (A_{i_j})_{g_j}$ and we have

$$(\omega_A^\bullet)_{f_j} \cong (\omega_{i_j}^\bullet)_{g_j}$$

in the derived category by Derived Categories of Schemes, Lemma 35.3.4. By Lemma 43.12.6 we find that the complex $(\omega_A^\bullet)_{f_j}$ is a dualizing complex over A_{f_j} for $j = 1, \dots, m$. This implies that ω_A^\bullet is dualizing by Lemma 43.12.7. \square

Definition 43.16.2. Let X be a locally Noetherian scheme. An object K of $D(\mathcal{O}_X)$ is called a *dualizing complex* if K satisfies the equivalent conditions of Lemma 43.16.1.

Please see remarks made at the beginning of this section.

Lemma 43.16.3. *Let A be a Noetherian ring and let $X = \text{Spec}(A)$. Let K, L be objects of $D(A)$. If $K \in D_{\text{Coh}}(A)$ and L has finite injective dimension, then*

$$R\mathcal{H}om(\widetilde{K}, \widetilde{L}) = R\widetilde{\text{Hom}}(K, L)$$

in $D(\mathcal{O}_X)$.

Proof. We may assume that L is given by a finite complex I^\bullet of injective A -modules. By induction on the length of I^\bullet and compatibility of the constructions with distinguished triangles, we reduce to the case that $L = I[0]$ where I is an injective A -module. In this case, Derived Categories of Schemes, Lemma 35.9.8, tells us that the n th cohomology sheaf of $R\mathcal{H}om(\widetilde{K}, \widetilde{L})$ is the sheaf associated to the presheaf

$$D(f) \longmapsto \text{Ext}_{A_f}^n(K \otimes_A A_f, I \otimes_A A_f)$$

Since A is Noetherian, the A_f -module $I \otimes_A A_f$ is injective (Lemma 43.3.9). Hence we see that

$$\begin{aligned} \text{Ext}_{A_f}^n(K \otimes_A A_f, I \otimes_A A_f) &= \text{Hom}_{A_f}(H^{-n}(K \otimes_A A_f), I \otimes_A A_f) \\ &= \text{Hom}_{A_f}(H^{-n}(K) \otimes_A A_f, I \otimes_A A_f) \\ &= \text{Hom}_A(H^{-n}(K), I) \otimes_A A_f \end{aligned}$$

The last equality because $H^{-n}(K)$ is a finite A -module. This proves that the canonical map

$$R\widetilde{\text{Hom}}(K, L) \longrightarrow R\mathcal{H}om(\widetilde{K}, \widetilde{L})$$

is a quasi-isomorphism in this case and the proof is done. □

Lemma 43.16.4. *Let K be a dualizing complex on a locally Noetherian scheme X . Then K is an object of $D_{\text{Coh}}(\mathcal{O}_X)$ and $D = R\mathcal{H}om(-, K)$ induces an anti-equivalence*

$$D : D_{\text{Coh}}(\mathcal{O}_X) \longrightarrow D_{\text{Coh}}(\mathcal{O}_X)$$

such that $D \circ D \cong \text{id}$. If X is quasi-compact, then D exchanges $D_{\text{Coh}}^+(\mathcal{O}_X)$ and $D_{\text{Coh}}^-(\mathcal{O}_X)$ and induces an equivalence $D_{\text{Coh}}^b(\mathcal{O}_X) \rightarrow D_{\text{Coh}}^b(\mathcal{O}_X)$.

Proof. Let $U \subset X$ be an affine open. Say $U = \text{Spec}(A)$ and let ω_A^\bullet be a dualizing complex for A corresponding to $K|_U$ as in Lemma 43.16.1. By Lemma 43.16.3 the diagram

$$\begin{array}{ccc} D_{\text{Coh}}(A) & \longrightarrow & D_{\text{Coh}}(\mathcal{O}_U) \\ \downarrow R\mathcal{H}om(-, \omega_A^\bullet) & & \downarrow R\mathcal{H}om(-, K|_U) \\ D_{\text{Coh}}(A) & \longrightarrow & D(\mathcal{O}_U) \end{array}$$

commutes. We conclude that D sends $D_{\text{Coh}}(\mathcal{O}_X)$ into $D_{\text{Coh}}(\mathcal{O}_X)$. Moreover, the canonical map

$$L \longrightarrow R\mathcal{H}om(R\mathcal{H}om(L, K), K)$$

(Cohomology on Sites, Lemma 21.26.5) is an isomorphism for all L because this is true on affines by Lemma 43.12.2. The statement on boundedness properties of the functor D in the quasi-compact case also follow from the corresponding statements of Lemma 43.12.2. □

43.17. Twisted inverse image

References for this section are [Nee96] and [LN07]. Let $f : X \rightarrow Y$ be a morphism of schemes. In some papers, a *twisted inverse image* for f is defined to be a right adjoint to the functor $Rf_* : D_{\text{QCoh}}(\mathcal{O}_X) \rightarrow D_{\text{QCoh}}(\mathcal{O}_Y)$. However, this terminology is not universally accepted and we refrain from giving a formal definition. We also will not use the notation $f^!$ for such a functor, as this would clash (for general morphisms f) with the notation in [Har66].

Lemma 43.17.1. *Let $f : X \rightarrow Y$ be a morphism between quasi-separated and quasi-compact schemes. The functor $Rf_* : D_{QCoh}(X) \rightarrow D_{QCoh}(Y)$ has a right adjoint.*

Proof. We will prove a right adjoint exists by verifying the hypotheses of Derived Categories, Proposition 13.35.2. First off, the category $D_{QCoh}(\mathcal{O}_X)$ has direct sums, see Derived Categories of Schemes, Lemma 35.3.1. The category $D_{QCoh}(\mathcal{O}_X)$ is compactly generated by Derived Categories of Schemes, Theorem 35.13.3. Since X and Y are quasi-compact and quasi-separated, so is f , see Schemes, Lemmas 25.21.14 and 25.21.15. Hence the functor Rf_* commutes with direct sums, see Derived Categories of Schemes, Lemma 35.4.2. This finishes the proof. \square

Example 43.17.2. Let $A \rightarrow B$ be a ring map. Let $Y = \text{Spec}(A)$ and $X = \text{Spec}(B)$ and $f : X \rightarrow Y$ the morphism corresponding to $A \rightarrow B$. Then Rf_* corresponds to restriction $D(B) \rightarrow D(A)$ via the equivalences $D(B) \rightarrow D_{QCoh}(\mathcal{O}_X)$ and $D(A) \rightarrow D_{QCoh}(\mathcal{O}_Y)$. Hence the right adjoint corresponds to the functor $K \mapsto R\text{Hom}(B, K)$ of Section 43.10.

Example 43.17.3. If $f : X \rightarrow Y$ is a separated finite type morphism of Noetherian schemes, then twisted inverse image does not map $D_{Coh}(\mathcal{O}_Y)$ into $D_{Coh}(\mathcal{O}_X)$. Namely, let k be a field and consider the morphism $f : \mathbf{A}_k^1 \rightarrow \text{Spec}(k)$. By Example 43.17.2 this corresponds to the question of whether $R\text{Hom}(B, -)$ maps $D_{Coh}(A)$ into $D_{Coh}(B)$ where $A = k$ and $B = k[x]$. This is not true because

$$R\text{Hom}(k[x], k) = \left(\prod_{n \geq 0} k \right) [0]$$

which is not a finite $k[x]$ -module. Hence $a(\mathcal{O}_Y)$ does not have coherent cohomology sheaves.

Example 43.17.4. If $f : X \rightarrow Y$ is a proper or even finite morphism of Noetherian schemes, then twisted inverse image does not map $D_{QCoh}^-(\mathcal{O}_Y)$ into $D_{QCoh}^-(\mathcal{O}_X)$. Namely, let k be a field, let $k[\epsilon]$ be the dual numbers over k , let $X = \text{Spec}(k)$, and let $Y = \text{Spec}(k[\epsilon])$. Then $\text{Ext}_{k[\epsilon]}^i(k, k)$ is nonzero for all $i \geq 0$. Hence $a(\mathcal{O}_Y)$ is not bounded above by Example 43.17.2.

Lemma 43.17.5. *Let $f : X \rightarrow Y$ be a morphism of quasi-compact and quasi-separated schemes. Let $a : D_{QCoh}(\mathcal{O}_Y) \rightarrow D_{QCoh}(\mathcal{O}_X)$ be the right adjoint to Rf_* of Lemma 43.17.1. Then a maps $D_{QCoh}^+(\mathcal{O}_Y)$ into $D_{QCoh}^+(\mathcal{O}_X)$.*

Proof. By Derived Categories of Schemes, Lemma 35.4.1 the functor Rf_* has finite cohomological dimension. In other words, there exist an integer N such that $H^i(Rf_*L) = 0$ for $i \geq N + c$ if $H^j(L) = 0$ for $j \geq c$. Say $K \in D_{QCoh}^+(\mathcal{O}_Y)$ has $H^k(K) = 0$ for $k \geq c$. Then

$$\text{Hom}_{D(\mathcal{O}_X)}(\tau_{\leq c-N}a(K), a(K)) = \text{Hom}_{D(\mathcal{O}_Y)}(Rf_*\tau_{\leq c-N}a(K), K) = 0$$

by what we said above. Clearly, this implies that $a(K)$ is bounded below. \square

We often want to know whether the twisted inverse image commutes with base change. Thus we consider a cartesian square

$$(43.17.5.1) \quad \begin{array}{ccc} X' & \xrightarrow{\quad} & X \\ f' \downarrow & & \downarrow f \\ Y' & \xrightarrow{\quad} & Y \end{array}$$

of quasi-compact and quasi-separated schemes. Denote

$$\begin{aligned} a &: D_{QCoh}(\mathcal{O}_Y) \rightarrow D_{QCoh}(\mathcal{O}_X), \\ a' &: D_{QCoh}(\mathcal{O}_{Y'}) \rightarrow D_{QCoh}(\mathcal{O}_{X'}), \\ b &: D_{QCoh}(\mathcal{O}_X) \rightarrow D_{QCoh}(\mathcal{O}_{X'}), \\ b' &: D_{QCoh}(\mathcal{O}_Y) \rightarrow D_{QCoh}(\mathcal{O}_{Y'}) \end{aligned}$$

the right adjoints to Rf_* , Rf'_* , Rg_* , and Rg'_* (Lemma 43.17.1). Since $Rf_* \circ Rg'_* = Rg_* \circ Rf'_*$ we get

$$b' \circ a = a' \circ b.$$

Another compatibility comes from the base change map of Cohomology, Remark 20.29.2. It induces a transformation of functors

$$Lg^* \circ Rf_* \rightarrow Rf'_* \circ L(g')^*$$

on derived categories of sheaves with quasi-coherent cohomology. Hence a transformation between the right adjoints in the opposite direction

$$a \circ Rg_* \leftarrow Rg'_* \circ a'$$

Lemma 43.17.6. *In diagram (43.17.5.1) assume that g is flat or more generally that f and g are Tor independent. Then $a \circ Rg_* \leftarrow Rg'_* \circ a'$ is an isomorphism.*

Proof. In this case the base change map $Lg^* \circ Rf_* K \rightarrow Rf'_* \circ L(g')^* K$ is an isomorphism for every K in $D_{QCoh}(\mathcal{O}_X)$ by Derived Categories of Schemes, Lemma 35.16.3. Thus the corresponding transformation between adjoint functors is an isomorphism as well. \square

Let $f : X \rightarrow Y$ be a morphism of quasi-compact and quasi-separated schemes. Let $V \subset Y$ be a quasi-compact open subscheme and set $U = f^{-1}(V)$. This gives a cartesian square

$$\begin{array}{ccc} U & \xrightarrow{j'} & X \\ f|_U \downarrow & & \downarrow f \\ V & \xrightarrow{j} & Y \end{array}$$

as in (43.17.5.1). By Lemma 43.17.6 we have $a \circ Rj_* = Rj'_* \circ a'$ where a and a' are the twisted inverse images corresponding to f and $f|_U$. Let $K \in D_{QCoh}(\mathcal{O}_Y)$. Then we get a map

$$(43.17.6.1) \quad a(K)|_U \rightarrow a(Rj_* K|_V)|_U = (Rj'_* a'(K|_V))|_U = a'(K|_V)$$

where the first arrow comes from the adjunction map $K \rightarrow Rj_* K|_V$.

Example 43.17.7. There is a finite morphism $f : X \rightarrow Y$ of Noetherian schemes such that (43.17.6.1) is not an isomorphism for some $K \in D_{Coh}(\mathcal{O}_Y)$. Namely, let $X = \text{Spec}(B) \rightarrow Y = \text{Spec}(A)$ with $A = k[x, \epsilon]$ where k is a field and $\epsilon^2 = 0$ and $B = k[x] = A/(\epsilon)$. For $n \in \mathbf{N}$ set $M_n = A/(\epsilon, x^n)$. Observe that

$$\text{Ext}_A^i(B, M_n) = M_n, \quad i \geq 0$$

because B has the free periodic resolution $\dots \rightarrow A \rightarrow A \rightarrow A$ with maps given by multiplication by ϵ . Consider the object $K = \bigoplus K_n[n] = \prod K_n[n]$ of $D_{Coh}(A)$

(equality in $D(A)$ by Derived Categories, Lemmas 13.31.2 and 13.32.2). Then we see that $a(K)$ corresponds to $R\text{Hom}(B, K)$ by Example 43.17.2 and

$$H^0(R\text{Hom}(B, K)) = \text{Ext}_A^0(B, K) = \prod_{n \geq 1} \text{Ext}_A^n(B, M_n) = \prod_{n \geq 1} M_n$$

by the above. But this module has elements which are not annihilated by any power of x , whereas the complex K does have every element of its cohomology annihilated by a power of x . In other words, for the map (43.17.6.1) with $V = D(x)$ and $U = D(x)$ and the complex K , the left hand side is nonzero and the right hand side is zero.

Lemma 43.17.8. *Let $f : X \rightarrow Y$ be a morphism of quasi-compact and quasi-separated schemes. Let $V \subset Y$ be quasi-compact open with inverse image $U \subset X$. If for every $Q \in D_{Q\text{Coh}}^+(\mathcal{O}_Y)$ supported on $Y \setminus V$ the twisted inverse image $a(Q)$ is supported on $X \setminus U$, then (43.17.6.1) is an isomorphism for all K in $D_{Q\text{Coh}}^+(\mathcal{O}_Y)$.*

Proof. Choose a distinguished triangle

$$K \rightarrow Rj_*K|_V \rightarrow Q \rightarrow K[1]$$

Observe that Q is supported on $Y \setminus V$ (Derived Categories of Schemes, Definition 35.6.4). Applying the twisted inverse image a we obtain a distinguished triangle

$$a(K) \rightarrow a(Rj_*K|_V) \rightarrow a(Q) \rightarrow a(K)[1]$$

on X . If $a(Q)$ is supported on $X \setminus U$, then restricting to U the map $a(K)|_U \rightarrow a(Rj_*K|_V)|_U$ is an isomorphism, i.e., (43.17.6.1) is an isomorphism. \square

Lemma 43.17.9. *Let $f : X \rightarrow Y$ be a proper¹ morphism of Noetherian schemes. The assumption and hence the conclusion of Lemma 43.17.8 holds for all opens V of Y .*

Proof. Let $Q \in D_{Q\text{Coh}}^+(\mathcal{O}_Y)$ be supported on $Y \setminus V$. To get a contradiction, assume that $a(Q)$ is not supported on $X \setminus U$. Then we can find a perfect complex P_U on U and a nonzero map $P_U \rightarrow a(Q)|_U$ (follows from Derived Categories of Schemes, Theorem 35.13.3). Then using Derived Categories of Schemes, Lemma 35.11.9 we may assume there is a perfect complex P on X and a map $P \rightarrow a(Q)$ whose restriction to U is nonzero. By definition of the twisted inverse image this map is adjoint to a map $Rf_*P \rightarrow Q$.

Because f is proper and X and Y Noetherian, the complex Rf_*P is pseudo-coherent, see Derived Categories of Schemes, Lemmas 35.5.1 and 35.9.4. Thus we may apply Derived Categories of Schemes, Lemma 35.14.3 and get a map $I \rightarrow \mathcal{O}_Y$ of perfect complexes whose restriction to V is an isomorphism such that the composition $I \otimes_{\mathcal{O}_Y}^L Rf_*P \rightarrow Rf_*P \rightarrow K$ is zero. By Derived Categories of Schemes, Lemma 35.16.1 we have $I \otimes_{\mathcal{O}_Y}^L Rf_*P = Rf_*(Lf^*I \otimes_{\mathcal{O}_X}^L P)$. We conclude that the composition

$$Lf^*I \otimes_{\mathcal{O}_X}^L P \rightarrow P \rightarrow a(K)$$

is zero. However, the restriction to U is the map $P|_U \rightarrow a(K)|_U$ which we assumed to be nonzero. This contradiction finishes the proof. \square

¹This proof works for those morphisms of quasi-compact and quasi-separated schemes such that Rf_*P is pseudo-coherent for all P perfect on X . It follows easily from a theorem of Kiehl [Kie72] that this holds if f is proper and pseudo-coherent. This is the correct generality for this lemma and some of the other results in this section.

Lemma 43.17.10. *Let $f : X \rightarrow Y$ be a proper morphism of Noetherian schemes. Let a be the twisted inverse image. Then the canonical map*

$$Rf_* R\mathcal{H}om(L, a(K)) \longrightarrow R\mathcal{H}om(Rf_* L, K)$$

is an isomorphism for all $L \in D_{QCoh}(\mathcal{O}_X)$ and all $K \in D_{QCoh}^+(\mathcal{O}_Y)$.

Proof. Since a is the right adjoint to Rf_* there is an adjunction map $Rf_* a(K) \rightarrow K$. On the other hand, there is a canonical map

$$Rf_* R\mathcal{H}om(L, a(K)) \rightarrow R\mathcal{H}om(Rf_* L, Rf_* a(K))$$

which works on the level of complexes. Combining these we obtain the map of the lemma. Taking $H^0(V, -)$ for an open V of Y with inverse image U in X we get

$$\mathrm{Hom}_{D(\mathcal{O}_U)}(L|_U, a(K)|_U) \longrightarrow \mathrm{Hom}_{D(\mathcal{O}_V)}(Rf_* L|_V, K|_V)$$

Since we've shown above that $a(K)|_U$ is the twisted inverse image of $K|_V$ (Lemma 43.17.9) the two sides of this arrow are isomorphic. We omit the verification that the two maps agree. A similar argument works for $H^n(V, -)$. Thus the map defined above is an isomorphism on cohomology and hence an isomorphism in the derived category. \square

Let $f : X \rightarrow Y$ be a morphism of quasi-compact and quasi-separated schemes. Let a be the twisted inverse image (Lemma 43.17.1). There is a canonical map

$$(43.17.10.1) \quad Lf^* K \otimes_{\mathcal{O}_X}^{\mathbf{L}} a(\mathcal{O}_Y) \longrightarrow a(K)$$

functorial in K and compatible with distinguished triangles. Namely, this map is adjoint to a map

$$Rf_*(Lf^* K \otimes_{\mathcal{O}_X}^{\mathbf{L}} a(\mathcal{O}_Y)) = K \otimes_{\mathcal{O}_X}^{\mathbf{L}} Rf_*(a(\mathcal{O}_Y)) \longrightarrow K$$

(equality by Derived Categories of Schemes, Lemma 35.16.1) for which we use the adjunction map $Rf_* a(\mathcal{O}_Y) \rightarrow \mathcal{O}_Y$ and the identity on K .

Lemma 43.17.11. *Let $f : X \rightarrow Y$ be a morphism of quasi-compact and quasi-separated schemes. The map (43.17.10.1) is an isomorphism for every perfect object K of $D(\mathcal{O}_Y)$.*

Proof. For a perfect object K on Y and $L \in D_{QCoh}(\mathcal{O}_X)$ we have

$$\begin{aligned} \mathrm{Hom}_{D(\mathcal{O}_Y)}(Rf_* L, K) &= \mathrm{Hom}_{D(\mathcal{O}_Y)}(Rf_* L \otimes_{\mathcal{O}_Y}^{\mathbf{L}} K^\wedge, \mathcal{O}_Y) \\ &= \mathrm{Hom}_{D(\mathcal{O}_X)}(L \otimes_{\mathcal{O}_X}^{\mathbf{L}} Lf^* K^\wedge, a(\mathcal{O}_Y)) \\ &= \mathrm{Hom}_{D(\mathcal{O}_X)}(L, a(\mathcal{O}_Y) \otimes_{\mathcal{O}_X}^{\mathbf{L}} Lf^* K) \end{aligned}$$

Hence the result by the Yoneda lemma. \square

Lemma 43.17.12. *Let $i : Z \rightarrow X$ be a closed immersion of quasi-compact and quasi-separated schemes. Let $a : D_{QCoh}(\mathcal{O}_X) \rightarrow D_{QCoh}(\mathcal{O}_Z)$ be the twisted inverse image, i.e., the right adjoint to Ri_* . Then there is a functorial isomorphism*

$$a(K) = R\mathcal{H}om(\mathcal{O}_Z, K)$$

for $K \in D_{QCoh}^+(\mathcal{O}_X)$.

Proof. By Lemma 43.11.2 the functor $R\mathcal{H}om(\mathcal{O}_Z, -)$ is a right adjoint to $Ri_* : D(\mathcal{O}_Z) \rightarrow D(\mathcal{O}_X)$. Moreover, by Lemma 43.11.4 and Lemma 43.17.5 both $R\mathcal{H}om(\mathcal{O}_Z, -)$ and a map $D_{QCoh}^+(\mathcal{O}_X)$ into $D_{QCoh}^+(\mathcal{O}_Z)$. Hence we obtain the isomorphism by uniqueness of adjoint functors. \square

Remark 43.17.13. The map (43.17.6.1) is a special case of a base change map. Namely, suppose that we have a diagram (43.17.5.1) where f and g are Tor independent. Let $K \in D_{QCoh}(\mathcal{O}_X)$. Then we can consider the composition (43.17.13.1)

$$L(g')^* a(K) \rightarrow L(g')^* a(Rg_* Lg^* K) = L(g')^* Rg'_* a'(Lg^* K) \rightarrow a'(Lg^* K)$$

We need the assumption on Tor independence to get the equality sign (the canonical map goes the other way). The two arrows come from the adjunction maps $\text{id} \rightarrow Rg_* Lg^*$ and $L(g')^* Rg'_* \rightarrow \text{id}$. Alternatively, we can think of (43.17.5.1) by adjointness of $L(g')^*$ and $R(g')_*$ as the map

$$a(K) \rightarrow a(Rg_* Lg^* K) = Rg'_* a'(Lg^* K)$$

If $M \in D_{QCoh}(\mathcal{O}_X)$ then on Yoneda functors this map is given by

$$\begin{aligned} \text{Hom}_X(M, a(K)) &= \text{Hom}_Y(Rf_* M, K) \\ &\rightarrow \text{Hom}_Y(Rf_* M, Rg_* Lg^* K) \\ &= \text{Hom}_{Y'}(Lg^* Rf_* M, Lg^* K) \\ &= \text{Hom}_{Y'}(Rf'_* L(g')^* M, Lg^* K) \\ &= \text{Hom}_{X'}(L(g')^* M, a'(Lg^* K)) \\ &= \text{Hom}_X(M, Rg'_* a'(Lg^* K)) \end{aligned}$$

which makes things a little bit more explicit.

Lemma 43.17.14. *Let $A \rightarrow A'$ be a ring map. Let X be a quasi-compact and quasi-separated scheme over A . Let $h : X' = X \times_{\text{Spec}(A)} \text{Spec}(A') \rightarrow X$ be the projection. Assume X and $\text{Spec}(B)$ are Tor independent over $\text{Spec}(A)$. We have*

$$\text{Hom}_X(M, K \otimes_{\mathcal{O}_X}^{\mathbf{L}} h_* \mathcal{O}_{X'}) = H^0(R\Gamma(X, R\mathcal{H}om(M, K)) \otimes_A^{\mathbf{L}} A')$$

in the following two cases

- (1) $M \in D(\mathcal{O}_X)$ is perfect and $K \in D_{QCoh}(X)$, or
- (2) $M \in D(\mathcal{O}_X)$ is pseudo-coherent, $K \in D_{QCoh}^+(X)$, and A' has finite tor dimension over A .

Proof. The complex $R\mathcal{H}om(M, K)$ is an object of $D_{QCoh}(\mathcal{O}_X)$ and we have

$$R\mathcal{H}om(M, K \otimes_{\mathcal{O}_X}^{\mathbf{L}} h_* \mathcal{O}_{X'}) = R\mathcal{H}om(M, K) \otimes_{\mathcal{O}_X}^{\mathbf{L}} h_* \mathcal{O}_{X'}$$

in both cases (details omitted; hints: you can check this when X is affine and use Derived Categories of Schemes, Lemma 35.9.8 to identify the $R\mathcal{H}om$ complexes). Hence, by replacing K by $R\mathcal{H}om(M, K)$ we reduce to proving

$$H^0(X, K \otimes_{\mathcal{O}_X}^{\mathbf{L}} h_* \mathcal{O}_{X'}) = H^0(R\Gamma(X, K) \otimes_A^{\mathbf{L}} A')$$

Note that the left hand side is equal to $H^0(X', Lh^* K)$ by Derived Categories of Schemes, Lemma 35.4.4. Hence the lemma is an example of by Derived Categories of Schemes, Lemma 35.16.3. \square

Lemma 43.17.15. *In diagram (43.17.5.1) assume*

- (1) $g : Y' \rightarrow Y$ is a morphism of affine schemes,
- (2) $f : X \rightarrow Y$ is proper,
- (3) Y Noetherian, and
- (4) f or g is flat.

Then the base change map (43.17.13.1) is an isomorphism for all $K \in D_{QCoh}(\mathcal{O}_X)$ if f is flat and for $K \in D_{QCoh}^+(\mathcal{O}_X)$ if g is flat.

Proof. Write $Y = \text{Spec}(A)$ and $Y' = \text{Spec}(A')$. As a base change of an affine morphism, the morphism g' is affine. Hence Rg'_* reflects isomorphisms, see Derived Categories of Schemes, Lemma 35.4.3. Thus (43.17.13.1) is an isomorphism for $K \in D_{QCoh}(\mathcal{O}_X)$ if and only if the map $a(K) \rightarrow a(Rg_*Lg^*K) = Rg'_*a'(Lg^*K)$ induces an isomorphism

$$a(K) \otimes_{\mathcal{O}_X}^{\mathbf{L}} g'_*\mathcal{O}_{X'} \rightarrow a(Rg_*Lg^*K)$$

(see Derived Categories of Schemes, Lemma 35.4.4). As $D_{QCoh}(\mathcal{O}_X)$ is generated by perfect objects (see Derived Categories of Schemes, Theorem 35.13.3), it suffices to check we obtain an isomorphism after applying the functor $\text{Hom}_X(M, -)$ where M is perfect on X . On the left hand side we get

$$\begin{aligned} \text{Hom}_X(M, a(K) \otimes_{\mathcal{O}_X}^{\mathbf{L}} g'_*\mathcal{O}_{X'}) &= H^0(R\Gamma(X, R\mathcal{H}om(M, a(K))) \otimes_A^{\mathbf{L}} A') \\ &= H^0(R\Gamma(Y, R\mathcal{H}om(Rf_*M, K)) \otimes_A^{\mathbf{L}} A') \end{aligned}$$

The first equality by Lemma 43.17.14. Observe that $R\Gamma(X, R\mathcal{H}om(M, a(K)))$ is the complex of A -modules whose cohomology groups are $\text{Hom}_X(M, a(K)[n])$ and similarly for $R\Gamma(Y, R\mathcal{H}om(Rf_*M, K))$, see Cohomology, Lemma 20.34.1. Hence the second equality follows from the definition of a . In the case that f is flat the complex Rf_*M is perfect on Y (Derived Categories of Schemes, Lemma 35.17.1) and in general the complex Rf_*M is pseudo-coherent on Y (Derived Categories of Schemes, Lemmas 35.5.1 and 35.9.4). Thus we get on the right hand side

$$\begin{aligned} \text{Hom}_X(M, a(Rg_*Lg^*K)) &= \text{Hom}_Y(Rf_*M, Rg_*Lg^*K) \\ &= \text{Hom}_Y(Rf_*M, K \otimes_{\mathcal{O}_Y}^{\mathbf{L}} g_*\mathcal{O}_{Y'}) \\ &= H^0(R\Gamma(Y, R\mathcal{H}om(Rf_*M, K)) \otimes_A^{\mathbf{L}} A') \end{aligned}$$

by the same arguments. Thus we get the same outcome as before. We omit the verification that our map induces the given identifications. \square

43.18. Flat and proper morphisms

The correct generality for this section would be to consider proper perfect morphisms of quasi-compact and quasi-separated schemes, see [LN07].

Lemma 43.18.1. *Let $f : X \rightarrow Y$ be a flat and proper morphism of Noetherian schemes. Let a be the twisted inverse image. Then a commutes with direct sums.*

Proof. Let P be a perfect object of $D(\mathcal{O}_X)$. By Derived Categories of Schemes, Lemma 35.17.1 the complex Rf_*P is perfect on Y . Let K_i be a family of objects of $D_{QCoh}(\mathcal{O}_Y)$. Then

$$\begin{aligned} \text{Hom}_{D(\mathcal{O}_X)}(P, a(\bigoplus K_i)) &= \text{Hom}_{D(\mathcal{O}_Y)}(Rf_*P, \bigoplus K_i) \\ &= \bigoplus \text{Hom}_{D(\mathcal{O}_Y)}(Rf_*P, K_i) \\ &= \bigoplus \text{Hom}_{D(\mathcal{O}_X)}(P, a(K_i)) \end{aligned}$$

because a perfect object is compact (Derived Categories of Schemes, Proposition 35.14.1). Since $D_{QCoh}(\mathcal{O}_X)$ has a perfect generator (Derived Categories of Schemes,

Theorem 35.13.3) we conclude that the map $\bigoplus a(K_i) \rightarrow a(\bigoplus K_i)$ is an isomorphism, i.e., a commutes with direct sums. \square

Lemma 43.18.2. *Let $f : X \rightarrow Y$ be a flat and proper morphism of Noetherian schemes. Let a be the twisted inverse image. Let $T \subset Y$ be closed. Then*

- (1) *if $Q \in D_{QCoh}(Y)$ is supported on T , then $a(Q)$ is supported on $f^{-1}(T)$,*
- (2) *the map (43.17.6.1) is an isomorphism for $K \in D_{QCoh}(\mathcal{O}_Y)$, and*
- (3) *the canonical map*

$$Rf_* R\mathcal{H}om(L, a(K)) \longrightarrow R\mathcal{H}om(Rf_* L, K)$$

is an isomorphism for all $L \in D_{QCoh}(\mathcal{O}_X)$ and all $K \in D_{QCoh}(\mathcal{O}_Y)$.

Proof. Arguing exactly as in the proof of Lemma 43.17.10 we see that (2) implies (3). Arguing exactly as in the proof of Lemma 43.17.8 we see that (1) implies (2).

Proof of (1). We will use the notation $D_{QCoh,T}(\mathcal{O}_Y)$ and $D_{QCoh,f^{-1}(T)}(\mathcal{O}_X)$ to denote complexes whose cohomology sheaves are supported on T and $f^{-1}(T)$. By Lemma 43.18.1 the functor a commutes with direct sums. Hence the strictly full, saturated, triangulated subcategory \mathcal{D} with objects

$$\{Q \in D_{QCoh,T}(\mathcal{O}_Y) \mid a(Q) \in D_{QCoh,f^{-1}(T)}(\mathcal{O}_X)\}$$

is preserved by direct sums (and hence derived colimits). On the other hand, the category $D_{QCoh,T}(\mathcal{O}_Y)$ is generated by a perfect object E (see Derived Categories of Schemes, Lemma 35.13.5). By Lemma 43.17.9 we see that $E \in \mathcal{D}$. By Derived Categories, Lemma 13.34.3 every object Q of $D_{QCoh,T}(\mathcal{O}_Y)$ is a derived colimit of a system $Q_1 \rightarrow Q_2 \rightarrow Q_3 \rightarrow \dots$ such that the cones of the transition maps are direct sums of shifts of E . Arguing by induction we see that $E_n \in \mathcal{D}$ for all n and finally that Q is in \mathcal{D} . Thus (1) is true. \square

Lemma 43.18.3. *Let $f : X \rightarrow Y$ be a proper flat morphism of Noetherian schemes. The map (43.17.10.1) is an isomorphism for every object K of $D_{QCoh}(\mathcal{O}_Y)$.*

Proof. By Lemma 43.18.1 we know that a commutes with direct sums. Hence the collection of objects of $D_{QCoh}(\mathcal{O}_Y)$ for which (43.17.10.1) is an isomorphism is a strictly full, saturated, triangulated subcategory of $D_{QCoh}(\mathcal{O}_Y)$ which is moreover preserved under taking direct sums. Since $D_{QCoh}(\mathcal{O}_Y)$ is a module category (Derived Categories of Schemes, Theorem 35.15.3) generated by a single perfect object (Derived Categories of Schemes, Theorem 35.13.3) we can argue as in More on Algebra, Remark 15.45.11 to see that it suffices to prove (43.17.10.1) is an isomorphism for a single perfect object. However, the result holds for perfect objects, see Lemma 43.17.11. \square

Lemma 43.18.4. *Let $f : X \rightarrow Y$ be a proper flat morphism of Noetherian schemes. Let $g : Y' \rightarrow Y$ be a morphism of finite type. Then the base change map (43.17.13.1) is an isomorphism for all $K \in D_{QCoh}(\mathcal{O}_X)$.*

Proof. By Lemma 43.18.2 formation of the functors a and a' commutes with restriction to opens of Y and Y' . Hence we may assume $Y' \rightarrow Y$ is a morphism of affine schemes. In this case the statement follows from Lemma 43.17.15. \square

Lemma 43.18.5. *Let $f : X = \mathbf{P}_Y^1 \rightarrow Y$ be the projection where Y is a Noetherian scheme. Let a be the twisted inverse image. Then $a(\mathcal{O}_Y)$ is isomorphic to $\mathcal{O}_X(-2)[1]$.*

Proof. Recall that there is an identification $Rf_*(\mathcal{O}_X(-2)[1]) = \mathcal{O}_Y$, see Cohomology of Schemes, Lemma 29.8.3 or 29.8.4. This determines a map $\mathcal{O}_X(-2)[1] \rightarrow a(\mathcal{O}_Y)$. By Lemma 43.17.9 construction of the twisted inverse image is local on the base. In particular, to check that $\mathcal{O}_X(-2)[1] \rightarrow a(\mathcal{O}_Y)$ is an isomorphism, we may work locally on Y . In other words, we may assume Y is affine. In the affine case the sheaves \mathcal{O}_X and $\mathcal{O}_X(-1)$ generate $D_{QCoh}(X)$, see Derived Categories of Schemes, Lemma 35.13.4. Hence it suffices to show that the maps

$$\begin{aligned} H^{-n+1}(X, \mathcal{O}(-2)) &= \mathrm{Hom}_{D(\mathcal{O}_X)}(\mathcal{O}_X[n], \mathcal{O}_X(-2)[1]) \\ &\rightarrow \mathrm{Hom}_{D(\mathcal{O}_X)}(\mathcal{O}_X[n], a(\mathcal{O}_Y)) \\ &= \mathrm{Hom}_{D(\mathcal{O}_Y)}(Rf_*(\mathcal{O}_X)[n], \mathcal{O}_Y) \\ &= H^{-n}(Y, \mathcal{O}_Y) \end{aligned}$$

and

$$\begin{aligned} H^{-n+1}(X, \mathcal{O}_X(-1)) &= \mathrm{Hom}_{D(\mathcal{O}_X)}(\mathcal{O}_X(-1)[n], \mathcal{O}_X(-2)[1]) \\ &\rightarrow \mathrm{Hom}_{D(\mathcal{O}_X)}(\mathcal{O}_X(-1)[n], a(\mathcal{O}_Y)) \\ &= \mathrm{Hom}_{D(\mathcal{O}_Y)}(Rf_*(\mathcal{O}_X(-1))[n], \mathcal{O}_Y) \\ &= 0 \end{aligned}$$

(where we used Cohomology of Schemes, Lemma 29.8.1) are isomorphisms for all $n \in \mathbf{Z}$. This is clear from the explicit computation of cohomology in Cohomology of Schemes, Lemma 29.8.1. \square

Example 43.18.6. The base change map (43.17.13.1) is not an isomorphism if f is proper and perfect and g is perfect. Let k be a field. Let $Y = \mathbf{A}_k^2$ and let $f : X \rightarrow Y$ be the blow up of Y in the origin. Denote $E \subset X$ the exceptional divisor. Then we can factor f as

$$X \xrightarrow{i} \mathbf{P}_Y^1 \xrightarrow{p} Y$$

This gives a factorization $a = c \circ b$ where b is the twisted inverse image for p and c is the twisted inverse image for i . Denote $\mathcal{O}(n)$ the Serre twist of the structure sheaf on \mathbf{P}_Y^1 and denote $\mathcal{O}_X(n)$ its restriction to X . Note that $X \subset \mathbf{P}_Y^1$ is cut out by a degree one equation, hence $\mathcal{O}(X) = \mathcal{O}(1)$. By Lemma 43.18.5 we have $b(\mathcal{O}_Y) = \mathcal{O}(-2)[1]$. By Lemma 43.17.12 we have

$$a(\mathcal{O}_Y) = c(b(\mathcal{O}_Y)) = c(\mathcal{O}(-2)[1]) = R\mathcal{H}om(\mathcal{O}_X, \mathcal{O}(-2)[1]) = \mathcal{O}_X(-1)$$

Last equality by Lemma 43.11.6. Hence the restriction of $a(\mathcal{O}_Y)$ to $E = \mathbf{P}_k^1$ is an invertible sheaf of degree -1 placed in cohomological degree 0. But on the other hand, $a'(\mathcal{O}_{\mathrm{Spec}(k)}) = \mathcal{O}_E(-2)[1]$ which is an invertible sheaf of degree -2 placed in cohomological degree -1 , so different.

43.19. Upper shriek functors

In this section all schemes are Noetherian (but we will make sure all the assumptions are mentioned explicitly in the statements).

Let S be a Noetherian scheme. We will say a scheme X over S has a compactification over S if there exists an open immersion $X \rightarrow \bar{X}$ into a scheme \bar{X} proper over S . If X has a compactification over S , then $X \rightarrow S$ is separated and of finite type. It is a theorem of Nagata (see [Con07], [Nag56], [Nag57], [Nag62a], and [Nag63])

that the converse is true as well (we will give a precise statement and a proof if we ever need this result).

Lemma 43.19.1. *Let S be a Noetherian scheme. Let X be a scheme over S which has a compactification over S .*

- (1) *Any two compactifications of X/S can be dominated by a third.*
- (2) *If $X \rightarrow Y \rightarrow S$ is a factorization with $Y \rightarrow S$ of separated of finite type, then X has a compactification over Y .*

Proof. Omitted. □

Given a morphism $f : X \rightarrow Y$ of compactifiable schemes over a Noetherian base scheme S , we will define an exact functor

$$f^! : D_{QCoh}^+(\mathcal{O}_Y) \rightarrow D_{QCoh}^+(\mathcal{O}_X)$$

of triangulated categories. Namely, we choose a compactification $X \rightarrow \bar{X}$ over Y which is possible by Lemma 43.19.1. Denote $\bar{f} : \bar{X} \rightarrow Y$ the structure morphism. We let $\bar{a} : D_{QCoh}^+(\mathcal{O}_Y) \rightarrow D_{QCoh}^+(\mathcal{O}_{\bar{X}})$ be the twisted inverse image, i.e., the right adjoint of $R\bar{f}_*$ constructed in Lemma 43.17.1. Then we set

$$f^!K = \bar{a}(K)|_X$$

for $K \in D_{QCoh}^+(\mathcal{O}_Y)$. The result is an object of $D_{QCoh}^+(\mathcal{O}_X)$ by Lemma 43.17.5.

Lemma 43.19.2. *The functor $f^!$ is independent of the choice of the compactification (up to canonical isomorphism). If f is an open immersion, then $f^! = f^*$. Moreover, if $f : X \rightarrow Y, g : Y \rightarrow Z$ are morphisms of compactifiable schemes over S , then there is a canonical isomorphism $f^! \circ g^! = (g \circ f)^!$.*

Proof. We first prove the last statement. Choose a compactification $Y \rightarrow \bar{Y} \rightarrow Z$ over Z and then choose a compactification $X \rightarrow \bar{X} \rightarrow \bar{Y}$ over \bar{Y} using Lemma 43.19.1. Let \bar{a} be the twisted inverse image for $\bar{X} \rightarrow \bar{Y}$ and let \bar{b} be the twisted inverse image for $\bar{Y} \rightarrow Z$. Then $\bar{a} \circ \bar{b}$ is the twisted inverse image for the composition $\bar{X} \rightarrow Z$. Let \bar{a}' be the twisted inverse image for $\bar{X} \times_{\bar{Y}} Y \rightarrow Y$. Let K be an object of $D_{QCoh}^+(\mathcal{O}_Z)$. To prove the statement on compositions it suffices to find a functorial isomorphism between

$$\bar{a}'(\bar{b}(K)|_Y) \quad \text{and} \quad \bar{a}(\bar{b}(K))|_{\bar{X} \times_{\bar{Y}} Y}$$

in $D(\mathcal{O}_{\bar{X}})$. The canonical map (43.17.6.1) from left to right is an isomorphism by Lemma 43.17.9.

Independence of the choice of the compactification is a special case of the argument above where $X \rightarrow Y$ is an isomorphism. The statement on open immersions is immediate from the construction (once it is shown to be independent of choices). □

Lemma 43.19.3. *Let S be a Noetherian scheme. Let Y be a compactifiable scheme over S and let $f : X = \mathbf{A}_Y^1 \rightarrow Y$ be the projection. Then there is a (noncanonical) isomorphism $f^!(-) \cong Lf^*(-)[1]$ of functors.*

Proof. Since $X = \mathbf{A}_Y^1 \subset \mathbf{P}_Y^1$ and since $\mathcal{O}_{\mathbf{P}_Y^1}(-2)|_X \cong \mathcal{O}_X$ this follows from Lemmas 43.18.5 and 43.18.3. □

Lemma 43.19.4. *Let S be a Noetherian scheme. Let Y be a compactifiable scheme over S and let $i : X \rightarrow Y$ be a closed immersion. Then there is a canonical isomorphism $i^!(-) = R\mathcal{H}om(\mathcal{O}_X, -)$ of functors.*

Proof. This is a restatement of Lemma 43.17.12. □

Lemma 43.19.5. *Let S be a Noetherian scheme. Let $f : X \rightarrow Y$ be a morphism of compactifiable schemes over S . If K is a dualizing complex for Y , then $f^!K$ is a dualizing complex for X .*

Proof. The question is local on X hence we may assume that X and Y are affine schemes mapping into an affine open of S . In this case we can factor $f : X \rightarrow Y$ as

$$X \xrightarrow{i} \mathbf{A}_Y^n \rightarrow \mathbf{A}_Y^{n-1} \rightarrow \dots \rightarrow \mathbf{A}_Y^1 \rightarrow Y$$

where i is a closed immersion. By Lemmas 43.19.3 and 43.12.9 and induction we see that the $p^!K$ is a dualizing complex on \mathbf{A}_Y^n where $p : \mathbf{A}_Y^n \rightarrow Y$ is the projection. Similarly, by Lemmas 43.12.8, 43.11.4, and 43.19.4 we see that $i^!$ transforms dualizing complexes into dualizing complexes. □

Étale Cohomology

44.1. Introduction

These are the notes of a course on étale cohomology taught by Johan de Jong at Columbia University in the Fall of 2009. The original note takers were Thibaut Pugin, Zachary Maddock and Min Lee. Over time we will add references to background material in the rest of the stacks project and provide rigorous proofs of all the statements.

44.2. Which sections to skip on a first reading?

We want to use the material in this chapter for the development of theory related to algebraic spaces, Deligne-Mumford stacks, algebraic stacks, etc. Thus we have added some pretty technical material to the original exposition of étale cohomology for schemes. The reader can recognize this material by the frequency of the word “topos”, or by discussions related to set theory, or by proofs dealing with very general properties of morphisms of schemes. Some of these discussions can be skipped on a first reading.

In particular, we suggest that the reader skip the following sections:

- (1) Comparing big and small topoi, Section 44.39.
- (2) Recovering morphisms, Section 44.41.
- (3) Push and pull, Section 44.42.
- (4) Property (A), Section 44.43.
- (5) Property (B), Section 44.44.
- (6) Property (C), Section 44.45.
- (7) Topological invariance of the small étale site, Section 44.46.
- (8) Integral universally injective morphisms, Section 44.48.
- (9) Big sites and pushforward, Section 44.49.
- (10) Exactness of big lower shriek, Section 44.50.

Besides these sections there are some sporadic results that may be skipped that the reader can recognize by the keywords given above.

44.3. Prologue

These lectures are about another cohomology theory. The first thing to remark is that the Zariski topology is not entirely satisfactory. One of the main reasons that it fails to give the results that we would want is that if X is a complex variety and \mathcal{F} is a constant sheaf then

$$H^i(X, \mathcal{F}) = 0, \quad \text{for all } i > 0.$$

The reason for that is the following. In an irreducible scheme (a variety in particular), any two nonempty open subsets meet, and so the restriction mappings of

a constant sheaf are surjective. We say that the sheaf is *flasque*. In this case, all higher Čech cohomology groups vanish, and so do all higher Zariski cohomology groups. In other words, there are “not enough” open sets in the Zariski topology to detect this higher cohomology.

On the other hand, if X is a smooth projective complex variety, then

$$H_{\text{Betti}}^{2 \dim X}(X(\mathbf{C}), \Lambda) = \Lambda \quad \text{for } \Lambda = \mathbf{Z}, \mathbf{Z}/n\mathbf{Z},$$

where $X(\mathbf{C})$ means the set of complex points of X . This is a feature that would be nice to replicate in algebraic geometry. In positive characteristic in particular.

44.4. The étale topology

It is very hard to simply “add” extra open sets to refine the Zariski topology. One efficient way to define a topology is to consider not only open sets, but also some schemes that lie over them. To define the étale topology, one considers all morphisms $\varphi : U \rightarrow X$ which are étale. If X is a smooth projective variety over \mathbf{C} , then this means

- (1) U is a disjoint union of smooth varieties, and
- (2) φ is (analytically) locally an isomorphism.

The word “analytically” refers to the usual (transcendental) topology over \mathbf{C} . So the second condition means that the derivative of φ has full rank everywhere (and in particular all the components of U have the same dimension as X).

A double cover – loosely defined as a finite degree 2 map between varieties – for example

$$\text{Spec}(\mathbf{C}[t]) \longrightarrow \text{Spec}(\mathbf{C}[t]), \quad t \longmapsto t^2$$

will not be an étale morphism if it has a fibre consisting of a single point. In the example this happens when $t = 0$. For a finite map between varieties over \mathbf{C} to be étale all the fibers should have the same number of points. Removing the point $t = 0$ from the source of the map in the example will make the morphism étale. But we can remove other points from the source of the morphism also, and the morphism will still be étale. To consider the étale topology, we have to look at all such morphisms. Unlike the Zariski topology, these need not be merely be open subsets of X , even though their images always are.

Definition 44.4.1. A family of morphisms $\{\varphi_i : U_i \rightarrow X\}_{i \in I}$ is called an *étale covering* if each φ_i is an étale morphism and their images cover X , i.e., $X = \bigcup_{i \in I} \varphi_i(U_i)$.

This “defines” the étale topology. In other words, we can now say what the sheaves are. An *étale sheaf* \mathcal{F} of sets (resp. abelian groups, vector spaces, etc) on X is the data:

- (1) for each étale morphism $\varphi : U \rightarrow X$ a set (resp. abelian group, vector space, etc) $\mathcal{F}(U)$,
- (2) for each pair U, U' of étale schemes over X , and each morphism $U \rightarrow U'$ over X (which is automatically étale) a restriction map $\rho_{U'}^U : \mathcal{F}(U) \rightarrow \mathcal{F}(U')$

These data have to satisfy the following *sheaf axiom*:

(*) for every étale covering $\{\varphi_i : U_i \rightarrow X\}_{i \in I}$, the diagram

$$\emptyset \longrightarrow \mathcal{F}(U) \longrightarrow \prod_{i \in I} \mathcal{F}(U_i) \rightrightarrows \prod_{i, j \in I} \mathcal{F}(U_i \times_U U_j)$$

is exact in the category of sets (resp. abelian groups, vector spaces, etc).

Remark 44.4.2. In the last statement, it is essential not to forget the case where $i = j$ which is in general a highly nontrivial condition (unlike in the Zariski topology). In fact, frequently important coverings have only one element.

Since the identity is an étale morphism, we can compute the global sections of an étale sheaf, and cohomology will simply be the corresponding right-derived functors. In other words, once more theory has been developed and statements have been made precise, there will be no obstacle to defining cohomology.

44.5. Feats of the étale topology

For a natural number $n \in \mathbf{N} = \{1, 2, 3, 4, \dots\}$ it is true that

$$H_{\text{étale}}^2(\mathbf{P}_{\mathbf{C}}^1, \mathbf{Z}/n\mathbf{Z}) = \mathbf{Z}/n\mathbf{Z}.$$

More generally, if X is a complex variety, then its étale Betti numbers with coefficients in a finite field agree with the usual Betti numbers of $X(\mathbf{C})$, i.e.,

$$\dim_{\mathbf{F}_q} H_{\text{étale}}^{2i}(X, \mathbf{F}_q) = \dim_{\mathbf{F}_q} H_{\text{Betti}}^{2i}(X(\mathbf{C}), \mathbf{F}_q).$$

This is extremely satisfactory. However, these equalities only hold for torsion coefficients, not in general. For integer coefficients, one has

$$H_{\text{étale}}^2(\mathbf{P}_{\mathbf{C}}^1, \mathbf{Z}) = 0.$$

There are ways to get back to nontorsion coefficients from torsion ones by a limit procedure which we will come to shortly.

44.6. A computation

How do we compute the cohomology of $\mathbf{P}_{\mathbf{C}}^1$ with coefficients $\Lambda = \mathbf{Z}/n\mathbf{Z}$? We use Čech cohomology. A covering of $\mathbf{P}_{\mathbf{C}}^1$ is given by the two standard opens U_0, U_1 , which are both isomorphic to $\mathbf{A}_{\mathbf{C}}^1$, and which intersection is isomorphic to $\mathbf{A}_{\mathbf{C}}^1 \setminus \{0\} = \mathbf{G}_{m, \mathbf{C}}$. It turns out that the Mayer-Vietoris sequence holds in étale cohomology. This gives an exact sequence

$$H_{\text{étale}}^{i-1}(U_0 \cap U_1, \Lambda) \rightarrow H_{\text{étale}}^i(\mathbf{P}_{\mathbf{C}}^1, \Lambda) \rightarrow H_{\text{étale}}^i(U_0, \Lambda) \oplus H_{\text{étale}}^i(U_1, \Lambda) \rightarrow H_{\text{étale}}^i(U_0 \cap U_1, \Lambda).$$

To get the answer we expect, we would need to show that the direct sum in the third term vanishes. In fact, it is true that, as for the usual topology,

$$H_{\text{étale}}^q(\mathbf{A}_{\mathbf{C}}^1, \Lambda) = 0 \quad \text{for } q \geq 1,$$

and

$$H_{\text{étale}}^q(\mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}, \Lambda) = \begin{cases} \Lambda & \text{if } q = 1, \text{ and} \\ 0 & \text{for } q \geq 2. \end{cases}$$

These results are already quite hard (what is an elementary proof?). Let us explain how we would compute this once the machinery of étale cohomology is at our disposal.

Higher cohomology. This is taken care of by the following general fact: if X is an affine curve over \mathbf{C} , then

$$H_{\text{étale}}^q(X, \mathbf{Z}/n\mathbf{Z}) = 0 \quad \text{for } q \geq 2.$$

This is proved by considering the generic point of the curve and doing some Galois cohomology. So we only have to worry about the cohomology in degree 1.

Cohomology in degree 1. We use the following identifications:

$$\begin{aligned}
 H_{\acute{e}tale}^1(X, \mathbf{Z}/n\mathbf{Z}) &= \left\{ \begin{array}{l} \text{sheaves of sets } \mathcal{F} \text{ on the } \acute{e}\text{tale site } X_{\acute{e}tale} \text{ endowed with an} \\ \text{action } \mathbf{Z}/n\mathbf{Z} \times \mathcal{F} \rightarrow \mathcal{F} \text{ such that } \mathcal{F} \text{ is a } \mathbf{Z}/n\mathbf{Z}\text{-torsor.} \end{array} \right\} / \cong \\
 &= \left\{ \begin{array}{l} \text{morphisms } Y \rightarrow X \text{ which are finite } \acute{e}\text{tale together} \\ \text{with a free } \mathbf{Z}/n\mathbf{Z} \text{ action such that } X = Y/(\mathbf{Z}/n\mathbf{Z}). \end{array} \right\} / \cong.
 \end{aligned}$$

The first identification is very general (it is true for any cohomology theory on a site) and has nothing to do with the étale topology. The second identification is a consequence of descent theory. The last set describes a collection of geometric objects on which we can get our hands.

The curve $\mathbf{A}_{\mathbf{C}}^1$ has no nontrivial finite étale covering and hence $H_{\acute{e}tale}^1(\mathbf{A}_{\mathbf{C}}^1, \mathbf{Z}/n\mathbf{Z}) = 0$. This can be seen either topologically or by using the argument in the next paragraph.

Let us describe the finite étale coverings $\varphi : Y \rightarrow \mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}$. It suffices to consider the case where Y is connected, which we assume. We are going to find out what Y can be by applying the Riemann-Hurwitz formula (of course this is a bit silly, and you can go ahead and skip the next section if you like). Say that this morphism is n to 1, and consider a projective compactification

$$\begin{array}{ccc}
 Y & \hookrightarrow & \bar{Y} \\
 \downarrow \varphi & & \downarrow \bar{\varphi} \\
 \mathbf{A}_{\mathbf{C}}^1 \setminus \{0\} & \hookrightarrow & \mathbf{P}_{\mathbf{C}}^1
 \end{array}$$

Even though φ is étale and does not ramify, $\bar{\varphi}$ may ramify at 0 and ∞ . Say that the preimages of 0 are the points y_1, \dots, y_r with indices of ramification e_1, \dots, e_r , and that the preimages of ∞ are the points y'_1, \dots, y'_s with indices of ramification d_1, \dots, d_s . In particular, $\sum e_i = n = \sum d_j$. Applying the Riemann-Hurwitz formula, we get

$$2g_Y - 2 = -2n + \sum (e_i - 1) + \sum (d_j - 1)$$

and therefore $g_Y = 0$, $r = s = 1$ and $e_1 = d_1 = n$. Hence $Y \cong \mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}$, and it is easy to see that $\varphi(z) = \lambda z^n$ for some $\lambda \in \mathbf{C}^*$. After reparametrizing Y we may assume $\lambda = 1$. Thus our covering is given by taking the n th root of the coordinate on $\mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}$.

Remember that we need to classify the coverings of $\mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}$ together with free $\mathbf{Z}/n\mathbf{Z}$ -actions on them. In our case any such action corresponds to an automorphism of Y sending z to $\zeta_n z$, where ζ_n is a primitive n th root of unity. There are $\phi(n)$ such actions (here $\phi(n)$ means the Euler function). Thus there are exactly $\phi(n)$ connected finite étale coverings with a given free $\mathbf{Z}/n\mathbf{Z}$ -action, each corresponding to a primitive n th root of unity. We leave it to the reader to see that the disconnected finite étale degree n coverings of $\mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}$ with a given free $\mathbf{Z}/n\mathbf{Z}$ -action correspond one-to-one with n th roots of 1 which are not primitive. In other words, this computation shows that

$$H_{\acute{e}tale}^1(\mathbf{A}_{\mathbf{C}}^1 \setminus \{0\}, \mathbf{Z}/n\mathbf{Z}) = \text{Hom}(\mu_n(\mathbf{C}), \mathbf{Z}/n\mathbf{Z}) \cong \mathbf{Z}/n\mathbf{Z}.$$

The first identification is canonical, the second isn't, see Remark 44.66.7. Since the proof of Riemann-Hurwitz does not use the computation of cohomology, the above actually constitutes a proof (provided we fill in the details on vanishing, etc).

44.7. Nontorsion coefficients

To study nontorsion coefficients, one makes the following definition:

$$H_{\acute{e}tale}^i(X, \mathbf{Q}_\ell) := \left(\lim_n H_{\acute{e}tale}^i(X, \mathbf{Z}/\ell^n \mathbf{Z}) \right) \otimes_{\mathbf{Z}_\ell} \mathbf{Q}_\ell.$$

The symbol \lim_n denote the *limit* of the system of cohomology groups $H_{\acute{e}tale}^i(X, \mathbf{Z}/\ell^n \mathbf{Z})$ indexed by n , see Categories, Section 4.21. Thus we will need to study systems of sheaves satisfying some compatibility conditions.

44.8. Sheaf theory

At this point we start talking about sites and sheaves in earnest. There is an amazing amount of useful abstract material that could fit in the next few sections. Some of this material is worked out in earlier chapters, such as the chapter on sites, modules on sites, and cohomology on sites. We try to refrain from adding to much material here, just enough so the material later in this chapter makes sense.

44.9. Presheaves

A reference for this section is Sites, Section 7.2.

Definition 44.9.1. Let \mathcal{C} be a category. A *presheaf of sets* (respectively, an *abelian presheaf*) on \mathcal{C} is a functor $\mathcal{C}^{opp} \rightarrow \mathit{Sets}$ (resp. Ab).

Terminology. If $U \in \text{Ob}(\mathcal{C})$, then elements of $\mathcal{F}(U)$ are called *sections* of \mathcal{F} over U . For $\varphi : V \rightarrow U$ in \mathcal{C} , the map $\mathcal{F}(\varphi) : \mathcal{F}(V) \rightarrow \mathcal{F}(U)$ is called the *restriction map* and is often denoted $s \mapsto s|_V$ or sometimes $s \mapsto \varphi^*s$. The notation $s|_V$ is ambiguous since the restriction map depends on φ , but it is a standard abuse of notation. We also use the notation $\Gamma(U, \mathcal{F}) = \mathcal{F}(U)$.

Saying that \mathcal{F} is a functor means that if $W \rightarrow V \rightarrow U$ are morphisms in \mathcal{C} and $s \in \Gamma(U, \mathcal{F})$ then $(s|_V)|_W = s|_W$, with the abuse of notation just seen. Moreover, the restriction mappings corresponding to the identity morphisms $\text{id}_U : U \rightarrow U$ are the identity.

The category of presheaves of sets (respectively of abelian presheaves) on \mathcal{C} is denoted $PSh(\mathcal{C})$ (resp. $PAb(\mathcal{C})$). It is the category of functors from \mathcal{C}^{opp} to Sets (resp. Ab), which is to say that the morphisms of presheaves are natural transformations of functors. We only consider the categories $PSh(\mathcal{C})$ and $PAb(\mathcal{C})$ when the category \mathcal{C} is small. (Our convention is that a category is small unless otherwise mentioned, and if it isn't small it should be listed in Categories, Remark 4.2.2.)

Example 44.9.2. Given an object $X \in \text{Ob}(\mathcal{C})$, we consider the functor

$$\begin{aligned} h_X : \quad \mathcal{C}^{opp} &\longrightarrow \mathit{Sets} \\ U &\longmapsto h_X(U) = \text{Mor}_{\mathcal{C}}(U, X) \\ V \xrightarrow{\varphi} U &\longmapsto \varphi \circ - : h_X(U) \rightarrow h_X(V). \end{aligned}$$

It is a presheaf, called the *representable presheaf associated to X*. It is not true that representable presheaves are sheaves in every topology on every site.

Lemma 44.9.3 (Yoneda). *Let \mathcal{C} be a category, and $X, Y \in \text{Ob}(\mathcal{C})$. There is a natural bijection*

$$\begin{array}{ccc} \text{Mor}_{\mathcal{C}}(X, Y) & \longrightarrow & \text{Mor}_{\text{PSh}(\mathcal{C})}(h_X, h_Y) \\ \psi & \longmapsto & h_{\psi} = \psi \circ - : h_X \rightarrow h_Y. \end{array}$$

Proof. See Categories, Lemma 4.3.5. □

44.10. Sites

Definition 44.10.1. Let \mathcal{C} be a category. A *family of morphisms with fixed target* $\mathcal{U} = \{\varphi_i : U_i \rightarrow U\}_{i \in I}$ is the data of

- (1) an object $U \in \mathcal{C}$,
- (2) a set I (possibly empty), and
- (3) for all $i \in I$, a morphism $\varphi_i : U_i \rightarrow U$ of \mathcal{C} with target U .

There is a notion of a *morphism of families of morphisms with fixed target*. A special case of that is the notion of a *refinement*. A reference for this material is Sites, Section 7.8.

Definition 44.10.2. A *site*¹ consists of a category \mathcal{C} and a set $\text{Cov}(\mathcal{C})$ consisting of families of morphisms with fixed target called *coverings*, such that

- (1) (isomorphism) if $\varphi : V \rightarrow U$ is an isomorphism in \mathcal{C} , then $\{\varphi : V \rightarrow U\}$ is a covering,
- (2) (locality) if $\{\varphi_i : U_i \rightarrow U\}_{i \in I}$ is a covering and for all $i \in I$ we are given a covering $\{\psi_{ij} : U_{ij} \rightarrow U_i\}_{j \in I_i}$, then

$$\{\varphi_i \circ \psi_{ij} : U_{ij} \rightarrow U\}_{(i,j) \in \prod_{i \in I} \{i\} \times I_i}$$

is also a covering, and

- (3) (base change) if $\{U_i \rightarrow U\}_{i \in I}$ is a covering and $V \rightarrow U$ is a morphism in \mathcal{C} , then
 - (a) for all $i \in I$ the fibre product $U_i \times_U V$ exists in \mathcal{C} , and
 - (b) $\{U_i \times_U V \rightarrow V\}_{i \in I}$ is a covering.

For us the category underlying a site is always “small”, i.e., its collection of objects form a set, and the collection of coverings of a site is a set as well (as in the definition above). We will mostly, in this chapter, leave out the arguments that cut down the collection of objects and coverings to a set. For further discussion, see Sites, Remark 7.6.3.

Example 44.10.3. If X is a topological space, then it has an associated site X_{Zar} defined as follows: the objects of X_{Zar} are the open subsets of X , the morphisms between these are the inclusion mappings, and the coverings are the usual topological (surjective) coverings. Observe that if $U, V \subset W \subset X$ are open subsets then $U \times_W V = U \cap V$ exists: this category has fiber products. All the verifications are trivial and everything works as expected.

¹What we call a site is called a category endowed with a pretopology in [AGV71, Exposé II, Définition 1.3]. In [Art62] it is called a category with a Grothendieck topology.

44.11. Sheaves

Definition 44.11.1. A presheaf \mathcal{F} of sets (resp. abelian presheaf) on a site \mathcal{C} is said to be a *separated presheaf* if for all coverings $\{\varphi_i : U_i \rightarrow U\}_{i \in I} \in \text{Cov}(\mathcal{C})$ the map

$$\mathcal{F}(U) \longrightarrow \prod_{i \in I} \mathcal{F}(U_i)$$

is injective. Here the map is $s \mapsto (s|_{U_i})_{i \in I}$. The presheaf \mathcal{F} is a *sheaf* if for all coverings $\{\varphi_i : U_i \rightarrow U\}_{i \in I} \in \text{Cov}(\mathcal{C})$, the diagram

$$(44.11.1.1) \quad \mathcal{F}(U) \longrightarrow \prod_{i \in I} \mathcal{F}(U_i) \rightrightarrows \prod_{i, j \in I} \mathcal{F}(U_i \times_U U_j),$$

where the first map is $s \mapsto (s|_{U_i})_{i \in I}$ and the two maps on the right are $(s_i)_{i \in I} \mapsto (s_i|_{U_i \times_U U_j})$ and $(s_i)_{i \in I} \mapsto (s_j|_{U_i \times_U U_j})$, is an equalizer diagram in the category of sets (resp. abelian groups).

Remark 44.11.2. For the empty covering (where $I = \emptyset$), this implies that $\mathcal{F}(\emptyset)$ is an empty product, which is a final object in the corresponding category (a singleton, for both *Sets* and *Ab*).

Example 44.11.3. Working this out for the site X_{Zar} associated to a topological space, see Example 44.10.3, gives the usual notion of sheaves.

Definition 44.11.4. We denote $Sh(\mathcal{C})$ (resp. $Ab(\mathcal{C})$) the full subcategory of $PSh(\mathcal{C})$ (resp. $PAb(\mathcal{C})$) whose objects are sheaves. This is the *category of sheaves of sets* (resp. *abelian sheaves*) on \mathcal{C} .

44.12. The example of G-sets

Let G be a group and define a site \mathcal{T}_G as follows: the underlying category is the category of G -sets, i.e., its objects are sets endowed with a left G -action and the morphisms are equivariant maps; and the coverings of \mathcal{T}_G are the families $\{\varphi_i : U_i \rightarrow U\}_{i \in I}$ satisfying $U = \bigcup_{i \in I} \varphi_i(U_i)$.

There is a special object in the site \mathcal{T}_G , namely the G -set G endowed with its natural action by left translations. We denote it ${}_G G$. Observe that there is a natural group isomorphism

$$\begin{aligned} \rho : G^{opp} &\longrightarrow \text{Aut}_{G\text{-Sets}}({}_G G) \\ g &\longmapsto (h \mapsto hg). \end{aligned}$$

In particular, for any presheaf \mathcal{F} , the set $\mathcal{F}({}_G G)$ inherits a G -action via ρ . (Note that by contravariance of \mathcal{F} , the set $\mathcal{F}({}_G G)$ is again a left G -set.) In fact, the functor

$$\begin{aligned} Sh(\mathcal{T}_G) &\longrightarrow G\text{-Sets} \\ \mathcal{F} &\longmapsto \mathcal{F}({}_G G) \end{aligned}$$

is an equivalence of categories. Its quasi-inverse is the functor $X \mapsto h_X$. Without giving the complete proof (which can be found in Sites, Section 7.9) let us try to explain why this is true.

- (1) If S is a G -set, we can decompose it into orbits $S = \coprod_{i \in I} O_i$. The sheaf axiom for the covering $\{O_i \rightarrow S\}_{i \in I}$ says that

$$\mathcal{F}(S) \longrightarrow \prod_{i \in I} \mathcal{F}(O_i) \rightrightarrows \prod_{i, j \in I} \mathcal{F}(O_i \times_S O_j)$$

is an equalizer. Observing that fibered products in $G\text{-Sets}$ are induced from fibered products in Sets , and using the fact that $\mathcal{F}(\emptyset)$ is a G -singleton, we get that

$$\prod_{i,j \in I} \mathcal{F}(O_i \times_S O_j) = \prod_{i \in I} \mathcal{F}(O_i)$$

and the two maps above are in fact the same. Therefore the sheaf axiom merely says that $\mathcal{F}(S) = \prod_{i \in I} \mathcal{F}(O_i)$.

(2) If S is the G -set $S = G/H$ and \mathcal{F} is a sheaf on \mathcal{T}_G , then we claim that

$$\mathcal{F}(G/H) = \mathcal{F}({}_G G)^H$$

and in particular $\mathcal{F}(\{*\}) = \mathcal{F}({}_G G)^G$. To see this, let's use the sheaf axiom for the covering $\{{}_G G \rightarrow G/H\}$ of S . We have

$$\begin{aligned} {}_G G \times_{G/H} {}_G G &\cong G \times H \\ (g_1, g_2) &\longmapsto (g_1, g_1 g_2^{-1}) \end{aligned}$$

is a disjoint union of copies of ${}_G G$ (as a G -set). Hence the sheaf axiom reads

$$\mathcal{F}(G/H) \longrightarrow \mathcal{F}({}_G G) \rightrightarrows \prod_{h \in H} \mathcal{F}({}_G G)$$

where the two maps on the right are $s \mapsto (s)_{h \in H}$ and $s \mapsto (hs)_{h \in H}$. Therefore $\mathcal{F}(G/H) = \mathcal{F}({}_G G)^H$ as claimed.

This doesn't quite prove the claimed equivalence of categories, but it shows at least that a sheaf \mathcal{F} is entirely determined by its sections over ${}_G G$. Details (and set theoretical remarks) can be found in Sites, Section 7.9.

44.13. Sheafification

Definition 44.13.1. Let \mathcal{F} be a presheaf on the site \mathcal{C} and $\mathcal{U} = \{U_i \rightarrow U\} \in \text{Cov}(\mathcal{C})$. We define the *zeroth Čech cohomology group* of \mathcal{F} with respect to \mathcal{U} by

$$\check{H}^0(\mathcal{U}, \mathcal{F}) = \left\{ (s_i)_{i \in I} \in \prod_{i \in I} \mathcal{F}(U_i) \text{ such that } s_i|_{U_i \times_U U_j} = s_j|_{U_i \times_U U_j} \right\}.$$

There is a canonical map $\mathcal{F}(U) \rightarrow \check{H}^0(\mathcal{U}, \mathcal{F})$, $s \mapsto (s|_{U_i})_{i \in I}$. We say that a *morphism of coverings* from a covering $\mathcal{V} = \{V_j \rightarrow V\}_{j \in J}$ to \mathcal{U} is a triple (χ, α, χ_j) , where $\chi : V \rightarrow U$ is a morphism, $\alpha : J \rightarrow I$ is a map of sets, and for all $j \in J$ the morphism χ_j fits into a commutative diagram

$$\begin{array}{ccc} V_j & \xrightarrow{\chi_j} & U_{\alpha(j)} \\ \downarrow & & \downarrow \\ V & \xrightarrow{\chi} & U. \end{array}$$

Given the data $\chi, \alpha, \{\chi_j\}_{j \in J}$ we define

$$\begin{aligned} \check{H}^0(\mathcal{U}, \mathcal{F}) &\longrightarrow \check{H}^0(\mathcal{V}, \mathcal{F}) \\ (s_i)_{i \in I} &\longmapsto (\chi_j^*(s_{\alpha(j)}))_{j \in J}. \end{aligned}$$

We then claim that

- (1) the map is well-defined, and
- (2) depends only on χ and is independent of the choice of $\alpha, \{\chi_j\}_{j \in J}$.

We omit the proof of the first fact. To see part (2), consider another triple (ψ, β, ψ_j) with $\chi = \psi$. Then we have the commutative diagram

$$\begin{array}{ccc}
 V_j & \xrightarrow{(\chi_j, \psi_j)} & U_{\alpha(j)} \times_U U_{\beta(j)} \\
 \downarrow & \swarrow & \searrow \\
 & U_{\alpha(j)} & U_{\beta(j)} \\
 \downarrow & \searrow & \swarrow \\
 V & \xrightarrow{\chi = \psi} & U
 \end{array}$$

Given a section $s \in \mathcal{F}(U)$, its image in $\mathcal{F}(V_j)$ under the map given by $(\chi, \alpha, \{\chi_j\}_{i \in J})$ is $\chi_j^* s_{\alpha(j)}$, and its image under the map given by $(\psi, \beta, \{\psi_j\}_{i \in J})$ is $\psi_j^* s_{\beta(j)}$. These two are equal since by assumption $s \in \check{H}(U, \mathcal{F})$ and hence both are equal to the pullback of the common value

$$s_{\alpha(j)}|_{U_{\alpha(j)} \times_U U_{\beta(j)}} = s_{\beta(j)}|_{U_{\alpha(j)} \times_U U_{\beta(j)}}$$

pulled back by the map (χ_j, ψ_j) in the diagram.

Theorem 44.13.2. *Let \mathcal{C} be a site and \mathcal{F} a presheaf on \mathcal{C} .*

(1) *The rule*

$$U \mapsto \mathcal{F}^+(U) := \operatorname{colim}_{\mathcal{U} \text{ covering of } U} \check{H}^0(\mathcal{U}, \mathcal{F})$$

is a presheaf. And the colimit is a directed one.

(2) *There is a canonical map of presheaves $\mathcal{F} \rightarrow \mathcal{F}^+$.*

(3) *If \mathcal{F} is a separated presheaf then \mathcal{F}^+ is a sheaf and the map in (2) is injective.*

(4) *\mathcal{F}^+ is a separated presheaf.*

(5) *$\mathcal{F}^\# = (\mathcal{F}^+)^+$ is a sheaf, and the canonical map induces a functorial isomorphism*

$$\operatorname{Hom}_{PSh(\mathcal{C})}(\mathcal{F}, \mathcal{G}) = \operatorname{Hom}_{Sh(\mathcal{C})}(\mathcal{F}^\#, \mathcal{G})$$

for any $\mathcal{G} \in Sh(\mathcal{C})$.

Proof. See Sites, Theorem 7.10.10. □

In other words, this means that the natural map $\mathcal{F} \rightarrow \mathcal{F}^\#$ is a left adjoint to the forgetful functor $Sh(\mathcal{C}) \rightarrow PSh(\mathcal{C})$.

44.14. Cohomology

The following is the basic result that makes it possible to define cohomology for abelian sheaves on sites.

Theorem 44.14.1. *The category of abelian sheaves on a site is an abelian category which has enough injectives.*

Proof. See Modules on Sites, Lemma 18.3.1 and Injectives, Theorem 19.7.4. □

So we can define cohomology as the right-derived functors of the sections functor: if $U \in \operatorname{Ob}(\mathcal{C})$ and $\mathcal{F} \in Ab(\mathcal{C})$,

$$H^p(U, \mathcal{F}) := R^p\Gamma(U, \mathcal{F}) = H^p(\Gamma(U, \mathcal{I}^\bullet))$$

where $\mathcal{F} \rightarrow \mathcal{I}^\bullet$ is an injective resolution. To do this, we should check that the functor $\Gamma(U, -)$ is left exact. This is true and is part of why the category $Ab(\mathcal{C})$ is abelian, see Modules on Sites, Lemma 18.3.1. For more general discussion of cohomology on sites (including the global sections functor and its right derived functors), see Cohomology on Sites, Section 21.3.

44.15. The fpqc topology

Before doing étale cohomology we study a bit the fpqc topology, since it works well for quasi-coherent sheaves.

Definition 44.15.1. Let T be a scheme. An *fpqc covering* of T is a family $\{\varphi_i : T_i \rightarrow T\}_{i \in I}$ such that

- (1) each φ_i is a flat morphism and $\bigcup_{i \in I} \varphi_i(T_i) = T$, and
- (2) for each affine open $U \subset T$ there exists a finite set K , a map $\mathbf{i} : K \rightarrow I$ and affine opens $U_{\mathbf{i}(k)} \subset T_{\mathbf{i}(k)}$ such that $U = \bigcup_{k \in K} \varphi_{\mathbf{i}(k)}(U_{\mathbf{i}(k)})$.

Remark 44.15.2. The first condition corresponds to fp, which stands for *fidèlement plat*, faithfully flat in french, and the second to qc, *quasi-compact*. The second part of the first condition is unnecessary when the second condition holds.

Example 44.15.3. Examples of fpqc coverings.

- (1) Any Zariski open covering of T is an fpqc covering.
- (2) A family $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$ is an fpqc covering if and only if $A \rightarrow B$ is a faithfully flat ring map.
- (3) If $f : X \rightarrow Y$ is flat, surjective and quasi-compact, then $\{f : X \rightarrow Y\}$ is an fpqc covering.
- (4) The morphism $\varphi : \coprod_{x \in \mathbf{A}_k^1} \text{Spec}(\mathcal{O}_{\mathbf{A}_k^1, x}) \rightarrow \mathbf{A}_k^1$, where k is a field, is flat and surjective. It is not quasi-compact, and in fact the family $\{\varphi\}$ is not an fpqc covering.
- (5) Write $\mathbf{A}_k^2 = \text{Spec}(k[x, y])$. Denote $i_x : D(x) \rightarrow \mathbf{A}_k^2$ and $i_y : D(y) \hookrightarrow \mathbf{A}_k^2$ the standard opens. Then the families $\{i_x, i_y, \text{Spec}(k[[x, y]]) \rightarrow \mathbf{A}_k^2\}$ and $\{i_x, i_y, \text{Spec}(\mathcal{O}_{\mathbf{A}_k^2, 0}) \rightarrow \mathbf{A}_k^2\}$ are fpqc coverings.

Lemma 44.15.4. *The collection of fpqc coverings on the category of schemes satisfies the axioms of site.*

Proof. See Topologies, Lemma 33.8.7. □

It seems that this lemma allows us to define the fpqc site of the category of schemes. However, there is a set theoretical problem that comes up when considering the fpqc topology, see Topologies, Section 33.8. It comes from our requirement that sites are “small”, but that no small category of schemes can contain a cofinal system of fpqc coverings of a given nonempty scheme. Although this does not strictly speaking prevent us from defining “partial” fpqc sites, it does not seem prudent to do so. The work-around is to allow the notion of a sheaf for the fpqc topology (see below) but to prohibit considering the category of all fpqc sheaves.

Definition 44.15.5. Let S be a scheme. The category of schemes over S is denoted Sch/S . Consider a functor $\mathcal{F} : (Sch/S)^{opp} \rightarrow Sets$, in other words a presheaf of sets. We say \mathcal{F} *satisfies the sheaf property for the fpqc topology* if for every fpqc covering $\{U_i \rightarrow U\}_{i \in I}$ of schemes over S the diagram (44.11.1.1) is an equalizer diagram.

We similarly say that \mathcal{F} satisfies the sheaf property for the Zariski topology if for every open covering $U = \bigcup_{i \in I} U_i$ the diagram (44.11.1.1) is an equalizer diagram. See Schemes, Definition 25.15.3. Clearly, this is equivalent to saying that for every scheme T over S the restriction of \mathcal{F} to the opens of T is a (usual) sheaf.

Lemma 44.15.6. *Let \mathcal{F} be a presheaf on Sch/S . Then \mathcal{F} satisfies the sheaf property for the fpqc topology if and only if*

- (1) \mathcal{F} satisfies the sheaf property with respect to the Zariski topology, and
- (2) for every faithfully flat morphism $\text{Spec}(B) \rightarrow \text{Spec}(A)$ of affine schemes over S , the sheaf axiom holds for the covering $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$. Namely, this means that

$$\mathcal{F}(\text{Spec}(A)) \longrightarrow \mathcal{F}(\text{Spec}(B)) \rightrightarrows \mathcal{F}(\text{Spec}(B \otimes_A B))$$

is an equalizer diagram.

Proof. See Topologies, Lemma 33.8.13. □

An alternative way to think of a presheaf \mathcal{F} on Sch/S which satisfies the sheaf condition for the fpqc topology is as the following data:

- (1) for each T/S , a usual (i.e., Zariski) sheaf \mathcal{F}_T on T_{Zar} ,
- (2) for every map $f : T' \rightarrow T$ over S , a restriction mapping $f^{-1}\mathcal{F}_T \rightarrow \mathcal{F}_{T'}$

such that

- (a) the restriction mappings are functorial,
- (b) if $f : T' \rightarrow T$ is an open immersion then the restriction mapping $f^{-1}\mathcal{F}_T \rightarrow \mathcal{F}_{T'}$ is an isomorphism, and
- (c) for every faithfully flat morphism $\text{Spec}(B) \rightarrow \text{Spec}(A)$ over S , the diagram

$$\mathcal{F}_{\text{Spec}(A)}(\text{Spec}(A)) \longrightarrow \mathcal{F}_{\text{Spec}(B)}(\text{Spec}(B)) \rightrightarrows \mathcal{F}_{\text{Spec}(B \otimes_A B)}(\text{Spec}(B \otimes_A B))$$

is an equalizer.

Data (1) and (2) and conditions (a), (b) give the data of a presheaf on Sch/S satisfying the sheaf condition for the Zariski topology. By Lemma 44.15.6 condition (c) then suffices to get the sheaf condition for the fpqc topology.

Example 44.15.7. Consider the presheaf

$$\begin{aligned} \mathcal{F} : (Sch/S)^{opp} &\longrightarrow Ab \\ T/S &\longmapsto \Gamma(T, \Omega_{T/S}). \end{aligned}$$

The compatibility of differentials with localization implies that \mathcal{F} is a sheaf on the Zariski site. However, it does not satisfy the sheaf condition for the fpqc topology. Namely, consider the case $S = \text{Spec}(\mathbf{F}_p)$ and the morphism

$$\varphi : V = \text{Spec}(\mathbf{F}_p[v]) \rightarrow U = \text{Spec}(\mathbf{F}_p[u])$$

given by mapping u to v^p . The family $\{\varphi\}$ is an fpqc covering, yet the restriction mapping $\mathcal{F}(U) \rightarrow \mathcal{F}(V)$ sends the generator du to $d(v^p) = 0$, so it is the zero map, and the diagram

$$\mathcal{F}(U) \xrightarrow{0} \mathcal{F}(V) \rightrightarrows \mathcal{F}(V \times_U V)$$

is not an equalizer. We will see later that \mathcal{F} does in fact give rise to a sheaf on the étale and smooth sites.

Lemma 44.15.8. *Any representable presheaf on Sch/S satisfies the sheaf condition for the fpqc topology.*

Proof. See Descent, Lemma 34.9.3. □

We will return to this later, since the proof of this fact uses descent for quasi-coherent sheaves, which we will discuss in the next section. A fancy way of expressing the lemma is to say that *the fpqc topology is weaker than the canonical topology*, or that the fpqc topology is *subcanonical*. In the setting of sites this is discussed in Sites, Section 7.13.

Remark 44.15.9. The fpqc is the finest topology that we will see. Hence any presheaf satisfying the sheaf condition for the fpqc topology will be a sheaf in the subsequent sites (étale, smooth, etc). In particular representable presheaves will be sheaves on the étale site of a scheme for example.

Example 44.15.10. Let S be a scheme. Consider the additive group scheme $\mathbf{G}_{a,S} = \mathbf{A}_S^1$ over S , see Groupoids, Example 38.5.3. The associated representable presheaf is given by

$$h_{\mathbf{G}_{a,S}}(T) = \text{Mor}_S(T, \mathbf{G}_{a,S}) = \Gamma(T, \mathcal{O}_T).$$

By the above we now know that this is a presheaf of sets which satisfies the sheaf condition for the fpqc topology. On the other hand, it is clearly a presheaf of rings as well. Hence we can think of this as a functor

$$\begin{array}{ccc} \mathcal{O} : (Sch/S)^{opp} & \longrightarrow & Rings \\ T/S & \longmapsto & \Gamma(T, \mathcal{O}_T) \end{array}$$

which satisfies the sheaf condition for the fpqc topology. Correspondingly there is a notion of \mathcal{O} -module, and so on and so forth.

44.16. Faithfully flat descent

Definition 44.16.1. Let $\mathcal{U} = \{t_i : T_i \rightarrow T\}_{i \in I}$ be a family of morphisms of schemes with fixed target. A *descent datum* for quasi-coherent sheaves with respect to \mathcal{U} is a family $(\mathcal{F}_i, \varphi_{ij})_{i,j \in I}$ where

- (1) for all i , \mathcal{F}_i is a quasi-coherent sheaf on T_i , and
- (2) for all $i, j \in I$ the map $\varphi_{ij} : \text{pr}_0^* \mathcal{F}_i \cong \text{pr}_1^* \mathcal{F}_j$ is an isomorphism on $T_i \times_T T_j$ such that the diagrams

$$\begin{array}{ccc} \text{pr}_0^* \mathcal{F}_i & \xrightarrow{\text{pr}_{01}^* \varphi_{ij}} & \text{pr}_1^* \mathcal{F}_j \\ & \searrow \text{pr}_{02}^* \varphi_{ik} & \swarrow \text{pr}_{12}^* \varphi_{jk} \\ & \text{pr}_2^* \mathcal{F}_k & \end{array}$$

commute on $T_i \times_T T_j \times_T T_k$.

This descent datum is called *effective* if there exist a quasi-coherent sheaf \mathcal{F} over T and \mathcal{O}_{T_i} -module isomorphisms $\varphi_i : t_i^* \mathcal{F} \cong \mathcal{F}_i$ satisfying the cocycle condition, namely

$$\varphi_{ij} = \text{pr}_1^*(\varphi_j) \circ \text{pr}_0^*(\varphi_i)^{-1}.$$

In this and the next section we discuss some ingredients of the proof of the following theorem, as well as some related material.

Theorem 44.16.2. *If $\mathcal{V} = \{T_i \rightarrow T\}_{i \in I}$ is an fpqc covering, then all descent data for quasi-coherent sheaves with respect to \mathcal{V} are effective.*

Proof. See Descent, Proposition 34.5.2. □

In other words, the fibered category of quasi-coherent sheaves is a stack on the fpqc site. The proof of the theorem is in two steps. The first one is to realize that for Zariski coverings this is easy (or well-known) using standard glueing of sheaves (see Sheaves, Section 6.33) and the locality of quasi-coherence. The second step is the case of an fpqc covering of the form $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$ where $A \rightarrow B$ is a faithfully flat ring map. This is a lemma in algebra, which we now present.

Descent of modules. If $A \rightarrow B$ is a ring map, we consider the complex

$$(B/A)_\bullet : B \rightarrow B \otimes_A B \rightarrow B \otimes_A B \otimes_A B \rightarrow \dots$$

where B is in degree 0, $B \otimes_A B$ in degree 1, etc, and the maps are given by

$$\begin{aligned} b &\mapsto 1 \otimes b - b \otimes 1, \\ b_0 \otimes b_1 &\mapsto 1 \otimes b_0 \otimes b_1 - b_0 \otimes 1 \otimes b_1 + b_0 \otimes b_1 \otimes 1, \\ &\text{etc.} \end{aligned}$$

Lemma 44.16.3. *If $A \rightarrow B$ is faithfully flat, then the complex $(B/A)_\bullet$ is exact in positive degrees, and $H^0((B/A)_\bullet) = A$.*

Proof. See Descent, Lemma 34.3.6. □

Grothendieck proves this in three steps. Firstly, he assumes that the map $A \rightarrow B$ has a section, and constructs an explicit homotopy to the complex where A is the only nonzero term, in degree 0. Secondly, he observes that to prove the result, it suffices to do so after a faithfully flat base change $A \rightarrow A'$, replacing B with $B' = B \otimes_A A'$. Thirdly, he applies the faithfully flat base change $A \rightarrow A' = B$ and remarks that the map $A' = B \rightarrow B' = B \otimes_A B$ has a natural section.

The same strategy proves the following lemma.

Lemma 44.16.4. *If $A \rightarrow B$ is faithfully flat and M is an A -module, then the complex $(B/A)_\bullet \otimes_A M$ is exact in positive degrees, and $H^0((B/A)_\bullet \otimes_A M) = M$.*

Proof. See Descent, Lemma 34.3.6. □

Definition 44.16.5. Let $A \rightarrow B$ be a ring map and N a B -module. A *descent datum* for N with respect to $A \rightarrow B$ is an isomorphism $\varphi : N \otimes_A B \cong B \otimes_A N$ of $B \otimes_A B$ -modules such that the diagram of $B \otimes_A B \otimes_A B$ -modules

$$\begin{array}{ccc} N \otimes_A B \otimes_A B & \xrightarrow{\varphi_{02}} & B \otimes_A N \otimes_A B \\ & \searrow \varphi_{01} & \swarrow \varphi_{12} \\ & B \otimes_A B \otimes_A N & \end{array}$$

commutes.

If $N' = B \otimes_A M$ for some A -module M , then it has a canonical descent datum given by the map

$$\begin{aligned} \varphi_{\text{can}} : \quad N' \otimes_A B &\rightarrow B \otimes_A N' \\ b_0 \otimes m \otimes b_1 &\mapsto b_0 \otimes b_1 \otimes m. \end{aligned}$$

Definition 44.16.6. A descent datum (N, φ) is called *effective* if there exists an A -module M such that $(N, \varphi) \cong (B \otimes_A M, \varphi_{\text{can}})$, with the obvious notion of isomorphism of descent data.

Theorem 44.16.2 is a consequence the following result.

Theorem 44.16.7. *If $A \rightarrow B$ is faithfully flat then descent data with respect to $A \rightarrow B$ are effective.*

Proof. See Descent, Proposition 34.3.9. See also Descent, Remark 34.3.11 for an alternative view of the proof. □

Remarks 44.16.8. The results on descent of modules have several applications:

- (1) The exactness of the Čech complex in positive degrees for the covering $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$ where $A \rightarrow B$ is faithfully flat. This will give some vanishing of cohomology.
- (2) If (N, φ) is a descent datum with respect to a faithfully flat map $A \rightarrow B$, then the corresponding A -module is given by

$$M = \text{Ker} \begin{pmatrix} N & \longrightarrow & B \otimes_A N \\ n & \longmapsto & 1 \otimes n - \varphi(n \otimes 1) \end{pmatrix}.$$

See Descent, Proposition 34.3.9.

44.17. Quasi-coherent sheaves

We can apply the descent of modules to study quasi-coherent sheaves.

Proposition 44.17.1. *For any quasi-coherent sheaf \mathcal{F} on S the presheaf*

$$\begin{aligned} \mathcal{F}^a : \quad \text{Sch}/S &\longrightarrow \text{Ab} \\ (f : T \rightarrow S) &\longmapsto \Gamma(T, f^* \mathcal{F}) \end{aligned}$$

is an \mathcal{O} -module which satisfies the sheaf condition for the fpqc topology.

Proof. This is proved in Descent, Lemma 34.7.1. We indicate the proof here. As established in Lemma 44.15.6, it is enough to check the sheaf property on Zariski coverings and faithfully flat morphisms of affine schemes. The sheaf property for Zariski coverings is standard scheme theory, since $\Gamma(U, i^* \mathcal{F}) = \mathcal{F}(U)$ when $i : U \hookrightarrow S$ is an open immersion.

For $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$ with $A \rightarrow B$ faithfully flat and $\mathcal{F}|_{\text{Spec}(A)} = \widetilde{M}$ this corresponds to the fact that $M = H^0((B/A)_\bullet \otimes_A M)$, i.e., that

$$0 \rightarrow M \rightarrow B \otimes_A M \rightarrow B \otimes_A B \otimes_A M$$

is exact by Lemma 44.16.4. □

There is an abstract notion of a quasi-coherent sheaf on a ringed site. We briefly introduce this here. For more information please consult Modules on Sites, Section 18.23. Let \mathcal{C} be a category, and let U be an object of \mathcal{C} . Then \mathcal{C}/U indicates the category of objects over U , see Categories, Example 4.2.13. If \mathcal{C} is a site, then \mathcal{C}/U is a site as well, namely the coverings of V/U are families $\{V_i/U \rightarrow V/U\}$ of morphisms of \mathcal{C}/U with fixed target such that $\{V_i \rightarrow V\}$ is a covering of \mathcal{C} . Moreover, given any sheaf \mathcal{F} on \mathcal{C} the *restriction* $\mathcal{F}|_{\mathcal{C}/U}$ (defined in the obvious manner) is a sheaf as well. See Sites, Section 7.24 for details.

Definition 44.17.2. Let \mathcal{C} be a *ringed site*, i.e., a site endowed with a sheaf of rings \mathcal{O} . A sheaf of \mathcal{O} -modules \mathcal{F} on \mathcal{C} is called *quasi-coherent* if for all $U \in \text{Ob}(\mathcal{C})$ there exists a covering $\{U_i \rightarrow U\}_{i \in I}$ of \mathcal{C} such that the restriction $\mathcal{F}|_{\mathcal{C}/U_i}$ is isomorphic to the cokernel of an \mathcal{O} -linear map of free \mathcal{O} -modules

$$\bigoplus_{k \in K} \mathcal{O}|_{\mathcal{C}/U_i} \longrightarrow \bigoplus_{l \in L} \mathcal{O}|_{\mathcal{C}/U_i}.$$

The direct sum over K is the sheaf associated to the presheaf $V \mapsto \bigoplus_{k \in K} \mathcal{O}(V)$ and similarly for the other.

Although it is useful to be able to give a general definition as above this notion is not well behaved in general.

Remark 44.17.3. In the case where \mathcal{C} has a final object, e.g. S , it suffices to check the condition of the definition for $U = S$ in the above statement. See Modules on Sites, Lemma 18.23.3.

Theorem 44.17.4 (Meta theorem on quasi-coherent sheaves). *Let S be a scheme. Let \mathcal{C} be a site. Assume that*

- (1) *the underlying category \mathcal{C} is a full subcategory of Sch/S ,*
- (2) *any Zariski covering of $T \in \text{Ob}(\mathcal{C})$ can be refined by a covering of \mathcal{C} ,*
- (3) *S/S is an object of \mathcal{C} ,*
- (4) *every covering of \mathcal{C} is an fpqc covering of schemes.*

Then the presheaf \mathcal{O} is a sheaf on \mathcal{C} and any quasi-coherent \mathcal{O} -module on $(\mathcal{C}, \mathcal{O})$ is of the form \mathcal{F}^a for some quasi-coherent sheaf \mathcal{F} on S .

Proof. After some formal arguments this is exactly Theorem 44.16.2. Details omitted. In Descent, Proposition 34.7.11 we prove a more precise version of the theorem for the big Zariski, fppf, étale, smooth, and syntomic sites of S , as well as the small Zariski and étale sites of S . \square

In other words, there is no difference between quasi-coherent modules on the scheme S and quasi-coherent \mathcal{O} -modules on sites \mathcal{C} as in the theorem. More precise statements for the big and small sites $(\text{Sch}/S)_{\text{fppf}}$, $S_{\text{étale}}$, etc can be found in Descent, Section 34.7. In this chapter we will sometimes refer to a “site as in Theorem 44.17.4” in order to conveniently state results which hold in any of those situations.

44.18. Čech cohomology

Our next goal is to use descent theory to show that $H^i(\mathcal{C}, \mathcal{F}^a) = H_{\text{Zar}}^i(S, \mathcal{F})$ for all quasi-coherent sheaves \mathcal{F} on S , and any site \mathcal{C} as in Theorem 44.17.4. To this end, we introduce Čech cohomology on sites. See [Art62] and Cohomology on Sites, Sections 21.9, 21.10 and 21.11 for more details.

Definition 44.18.1. Let \mathcal{C} be a category, $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ a family of morphisms of \mathcal{C} with fixed target, and $\mathcal{F} \in \text{PAb}(\mathcal{C})$ an abelian presheaf. We define the *Čech complex* $\check{\mathcal{C}}^\bullet(\mathcal{U}, \mathcal{F})$ by

$$\prod_{i_0 \in I} \mathcal{F}(U_{i_0}) \rightarrow \prod_{i_0, i_1 \in I} \mathcal{F}(U_{i_0} \times_U U_{i_1}) \rightarrow \prod_{i_0, i_1, i_2 \in I} \mathcal{F}(U_{i_0} \times_U U_{i_1} \times_U U_{i_2}) \rightarrow \dots$$

where the first term is in degree 0, and the maps are the usual ones. Again, it is essential to allow the case $i_0 = i_1$ etc. The *Čech cohomology groups* are defined by

$$\check{H}^p(\mathcal{U}, \mathcal{F}) = H^p(\check{\mathcal{C}}^\bullet(\mathcal{U}, \mathcal{F})).$$

Lemma 44.18.2. *The functor $\check{C}^\bullet(\mathcal{U}, -)$ is exact on the category $PAb(\mathcal{C})$.*

In other words, if $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3 \rightarrow 0$ is a short exact sequence of presheaves of abelian groups, then

$$0 \rightarrow \check{C}^\bullet(\mathcal{U}, \mathcal{F}_1) \rightarrow \check{C}^\bullet(\mathcal{U}, \mathcal{F}_2) \rightarrow \check{C}^\bullet(\mathcal{U}, \mathcal{F}_3) \rightarrow 0$$

is a short exact sequence of complexes.

Proof. This follows at once from the definition of a short exact sequence of presheaves. Namely, as the category of abelian presheaves is the category of functors on some category with values in Ab , it is automatically an abelian category: a sequence $\mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3$ is exact in PAb if and only if for all $U \in \text{Ob}(\mathcal{C})$, the sequence $\mathcal{F}_1(U) \rightarrow \mathcal{F}_2(U) \rightarrow \mathcal{F}_3(U)$ is exact in Ab . So the complex above is merely a product of short exact sequences in each degree. See also Cohomology on Sites, Lemma 21.10.1. \square

This shows that $\check{H}^\bullet(\mathcal{U}, -)$ is a δ -functor. We now proceed to show that it is a universal δ -functor. We thus need to show that it is an *effaceable* functor. We start by recalling the Yoneda lemma.

Lemma 44.18.3 (Yoneda Lemma). *For any presheaf \mathcal{F} on a category \mathcal{C} there is a functorial isomorphism*

$$\text{Hom}_{PSh(\mathcal{C})}(h_U, \mathcal{F}) = \mathcal{F}(U).$$

Proof. See Categories, Lemma 4.3.5. \square

Given a set E we denote (in this section) $\mathbf{Z}[E]$ the free abelian group on E . In a formula $\mathbf{Z}[E] = \bigoplus_{e \in E} \mathbf{Z}$, i.e., $\mathbf{Z}[E]$ is a free \mathbf{Z} -module having a basis consisting of the elements of E . Using this notation we introduce the free abelian presheaf on a presheaf of sets.

Definition 44.18.4. Let \mathcal{C} be a category. Given a presheaf of sets \mathcal{G} , we define the *free abelian presheaf on \mathcal{G}* , denoted $\mathbf{Z}_{\mathcal{G}}$, by the rule

$$\mathbf{Z}_{\mathcal{G}}(U) = \mathbf{Z}[\mathcal{G}(U)]$$

for $U \in \text{Ob}(\mathcal{C})$ with restriction maps induced by the restriction maps of \mathcal{G} . In the special case $\mathcal{G} = h_U$ we write simply $\mathbf{Z}_U = \mathbf{Z}_{h_U}$.

The functor $\mathcal{G} \mapsto \mathbf{Z}_{\mathcal{G}}$ is left adjoint to the forgetful functor $PAb(\mathcal{C}) \rightarrow PSh(\mathcal{C})$. Thus, for any presheaf \mathcal{F} , there is a canonical isomorphism

$$\text{Hom}_{PAb(\mathcal{C})}(\mathbf{Z}_U, \mathcal{F}) = \text{Hom}_{PSh(\mathcal{C})}(h_U, \mathcal{F}) = \mathcal{F}(U)$$

the last equality by the Yoneda lemma. In particular, we have the following result.

Lemma 44.18.5. *The Čech complex $\check{C}^\bullet(\mathcal{U}, \mathcal{F})$ can be described explicitly as follows*

$$\begin{aligned} \check{C}^\bullet(\mathcal{U}, \mathcal{F}) &= \left(\prod_{i_0 \in I} \text{Hom}_{PAb(\mathcal{C})}(\mathbf{Z}_{U_{i_0}}, \mathcal{F}) \rightarrow \prod_{i_0, i_1 \in I} \text{Hom}_{PAb(\mathcal{C})}(\mathbf{Z}_{U_{i_0} \times_U U_{i_1}}, \mathcal{F}) \rightarrow \dots \right) \\ &= \text{Hom}_{PAb(\mathcal{C})} \left(\left(\bigoplus_{i_0 \in I} \mathbf{Z}_{U_{i_0}} \leftarrow \bigoplus_{i_0, i_1 \in I} \mathbf{Z}_{U_{i_0} \times_U U_{i_1}} \leftarrow \dots \right), \mathcal{F} \right) \end{aligned}$$

Proof. This follows from the formula above. See Cohomology on Sites, Lemma 21.10.3. \square

This reduces us to studying only the complex in the first argument of the last Hom.

Lemma 44.18.6. *The complex of abelian presheaves*

$$\mathbf{Z}_{\mathcal{U}}^{\bullet} : \bigoplus_{i_0 \in I} \mathbf{Z}_{U_{i_0}} \leftarrow \bigoplus_{i_0, i_1 \in I} \mathbf{Z}_{U_{i_0} \times_U U_{i_1}} \leftarrow \bigoplus_{i_0, i_1, i_2 \in I} \mathbf{Z}_{U_{i_0} \times_U U_{i_1} \times_U U_{i_2}} \leftarrow \dots$$

is exact in all degrees except 0 in $PAb(\mathcal{C})$.

Proof. For any $V \in \text{Ob}(\mathcal{C})$ the complex of abelian groups $\mathbf{Z}_{\mathcal{U}}^{\bullet}(V)$ is

$$\mathbf{Z} \left[\coprod_{i_0 \in I} \text{Mor}_{\mathcal{C}}(V, U_{i_0}) \right] \leftarrow \mathbf{Z} \left[\coprod_{i_0, i_1 \in I} \text{Mor}_{\mathcal{C}}(V, U_{i_0} \times_U U_{i_1}) \right] \leftarrow \dots = \bigoplus_{\varphi: V \rightarrow U} \left(\mathbf{Z} \left[\coprod_{i_0 \in I} \text{Mor}_{\varphi}(V, U_{i_0}) \right] \leftarrow \mathbf{Z} \left[\coprod_{i_0, i_1 \in I} \text{Mor}_{\varphi}(V, U_{i_0} \times_U U_{i_1}) \right] \leftarrow \dots \right)$$

where

$$\text{Mor}_{\varphi}(V, U_i) = \{V \rightarrow U_i \text{ such that } V \rightarrow U_i \rightarrow U \text{ equals } \varphi\}.$$

Set $S_{\varphi} = \coprod_{i \in I} \text{Mor}_{\varphi}(V, U_i)$, so that

$$\mathbf{Z}_{\mathcal{U}}^{\bullet}(V) = \bigoplus_{\varphi: V \rightarrow U} \left(\mathbf{Z}[S_{\varphi}] \leftarrow \mathbf{Z}[S_{\varphi} \times S_{\varphi}] \leftarrow \mathbf{Z}[S_{\varphi} \times S_{\varphi} \times S_{\varphi}] \leftarrow \dots \right).$$

Thus it suffices to show that for each $S = S_{\varphi}$, the complex

$$\mathbf{Z}[S] \leftarrow \mathbf{Z}[S \times S] \leftarrow \mathbf{Z}[S \times S \times S] \leftarrow \dots$$

is exact in negative degrees. To see this, we can give an explicit homotopy. Fix $s \in S$ and define $K : n_{(s_0, \dots, s_p)} \mapsto n_{(s, s_0, \dots, s_p)}$. One easily checks that K is a nullhomotopy for the operator

$$\delta : \eta_{(s_0, \dots, s_p)} \mapsto \sum_{i=0}^p (-1)^i \eta_{(s_0, \dots, \hat{s}_i, \dots, s_p)}.$$

See Cohomology on Sites, Lemma 21.10.4 for more details. □

Lemma 44.18.7. *Let \mathcal{C} be a category. If \mathcal{I} is an injective object of $PAb(\mathcal{C})$ and \mathcal{U} is a family of morphisms with fixed target in \mathcal{C} , then $\check{H}^p(\mathcal{U}, \mathcal{I}) = 0$ for all $p > 0$.*

Proof. The Čech complex is the result of applying the functor $\text{Hom}_{PAb(\mathcal{C})}(-, \mathcal{I})$ to the complex $\mathbf{Z}_{\mathcal{U}}^{\bullet}$, i.e.,

$$\check{H}^p(\mathcal{U}, \mathcal{I}) = H^p(\text{Hom}_{PAb(\mathcal{C})}(\mathbf{Z}_{\mathcal{U}}^{\bullet}, \mathcal{I})).$$

But we have just seen that $\mathbf{Z}_{\mathcal{U}}^{\bullet}$ is exact in negative degrees, and the functor $\text{Hom}_{PAb(\mathcal{C})}(-, \mathcal{I})$ is exact, hence $\text{Hom}_{PAb(\mathcal{C})}(\mathbf{Z}_{\mathcal{U}}^{\bullet}, \mathcal{I})$ is exact in positive degrees. □

Theorem 44.18.8. *On $PAb(\mathcal{C})$ the functors $\check{H}^p(\mathcal{U}, -)$ are the right derived functors of $\check{H}^0(\mathcal{U}, -)$.*

Proof. By the Lemma 44.18.7, the functors $\check{H}^p(\mathcal{U}, -)$ are universal δ -functors since they are effaceable. So are the right derived functors of $\check{H}^0(\mathcal{U}, -)$. Since they agree in degree 0, they agree by the universal property of universal δ -functors. For more details see Cohomology on Sites, Lemma 21.10.6. □

Remark 44.18.9. Observe that all of the preceding statements are about presheaves so we haven't made use of the topology yet.

44.19. The Čech-to-cohomology spectral sequence

This spectral sequence is fundamental in proving foundational results on cohomology of sheaves.

Lemma 44.19.1. *The forgetful functor $Ab(\mathcal{C}) \rightarrow PAb(\mathcal{C})$ transforms injectives into injectives.*

Proof. This is formal using the fact that the forgetful functor has a left adjoint, namely sheafification, which is an exact functor. For more details see Cohomology on Sites, Lemma 21.11.1. \square

Theorem 44.19.2. *Let \mathcal{C} be a site. For any covering $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ of $U \in \text{Ob}(\mathcal{C})$ and any abelian sheaf \mathcal{F} on \mathcal{C} there is a spectral sequence*

$$E_2^{p,q} = \check{H}^p(\mathcal{U}, \underline{H}^q(\mathcal{F})) \Rightarrow H^{p+q}(U, \mathcal{F}),$$

where $\underline{H}^q(\mathcal{F})$ is the abelian presheaf $V \mapsto H^q(V, \mathcal{F})$.

Proof. Choose an injective resolution $\mathcal{F} \rightarrow \mathcal{I}^\bullet$ in $Ab(\mathcal{C})$, and consider the double complex $\check{\mathcal{C}}^\bullet(\mathcal{U}, \mathcal{I}^\bullet)$ and the maps

$$\begin{array}{ccc} \Gamma(U, \mathcal{I}^\bullet) & \longrightarrow & \check{\mathcal{C}}^\bullet(\mathcal{U}, \mathcal{I}^\bullet) \\ & & \uparrow \\ & & \check{\mathcal{C}}^\bullet(\mathcal{U}, \mathcal{F}) \end{array}$$

Here the horizontal map is the natural map $\Gamma(U, \mathcal{I}^\bullet) \rightarrow \check{\mathcal{C}}^0(\mathcal{U}, \mathcal{I}^\bullet)$ to the left column, and the vertical map is induced by $\mathcal{F} \rightarrow \mathcal{I}^0$ and lands in the bottom row. By assumption, \mathcal{I}^\bullet is a complex of injectives in $Ab(\mathcal{C})$, hence by Lemma 44.19.1, it is a complex of injectives in $PAb(\mathcal{C})$. Thus, the rows of the double complex are exact in positive degrees (Lemma 44.18.7), and the kernel of the horizontal map is equal to $\Gamma(U, \mathcal{I}^\bullet)$, since \mathcal{I}^\bullet is a complex of sheaves. In particular, the cohomology of the total complex is the standard cohomology of the global sections functor $H^0(U, \mathcal{F})$.

For the vertical direction, the q th cohomology group of the p th column is

$$\prod_{i_0, \dots, i_p} H^q(U_{i_0} \times_U \dots \times_U U_{i_p}, \mathcal{F}) = \prod_{i_0, \dots, i_p} \underline{H}^q(\mathcal{F})(U_{i_0} \times_U \dots \times_U U_{i_p})$$

in the entry $E_1^{p,q}$. So this is a standard double complex spectral sequence, and the E_2 -page is as prescribed. For more details see Cohomology on Sites, Lemma 21.11.6. \square

Remark 44.19.3. This is a Grothendieck spectral sequence for the composition of functors

$$Ab(\mathcal{C}) \longrightarrow PAb(\mathcal{C}) \xrightarrow{\check{H}^0} Ab.$$

44.20. Big and small sites of schemes

Let S be a scheme. Let τ be one of the topologies we will be discussing. Thus $\tau \in \{fppf, syntomic, smooth, \acute{e}tale, Zariski\}$. Of course if you are only interested in the étale topology, then you can simply assume $\tau = \acute{e}tale$ throughout. Moreover, we will discuss étale morphisms, étale coverings, and étale sites in more detail starting in Section 44.25. In order to proceed with the discussion of cohomology

of quasi-coherent sheaves it is convenient to introduce the big τ -site and in case $\tau \in \{\acute{e}tale, Zariski\}$, the small τ -site of S . In order to do this we first introduce the notion of a τ -covering.

Definition 44.20.1. (See Topologies, Definitions 33.7.1, 33.6.1, 33.5.1, 33.4.1, and 33.3.1.) Let $\tau \in \{fppf, syntomic, smooth, \acute{e}tale, Zariski\}$. A family of morphisms of schemes $\{f_i : T_i \rightarrow T\}_{i \in I}$ with fixed target is called a τ -covering if and only if each f_i is flat of finite presentation, syntomic, smooth, $\acute{e}tale$, resp. an open immersion, and we have $\bigcup f_i(T_i) = T$.

It turns out that the class of all τ -coverings satisfies the axioms (1), (2) and (3) of Definition 44.10.2 (our definition of a site), see Topologies, Lemmas 33.7.3, 33.6.3, 33.5.3, 33.4.3, and 33.3.2. In order to be able to compare any of these new topologies to the fpqc topology and to use the preceding results on descent on modules we single out a special class of τ -coverings of affine schemes called standard coverings.

Definition 44.20.2. (See Topologies, Definitions 33.7.5, 33.6.5, 33.5.5, 33.4.5, and 33.3.4.) Let $\tau \in \{fppf, syntomic, smooth, \acute{e}tale, Zariski\}$. Let T be an affine scheme. A *standard τ -covering* of T is a family $\{f_j : U_j \rightarrow T\}_{j=1, \dots, m}$ with each U_j is affine, and each f_j flat and of finite presentation, standard syntomic, standard smooth, $\acute{e}tale$, resp. the immersion of a standard principal open in T and $T = \bigcup f_j(U_j)$.

Lemma 44.20.3. *Let $\tau \in \{fppf, syntomic, smooth, \acute{e}tale, Zariski\}$. Any τ -covering of an affine scheme can be refined by a standard τ -covering.*

Proof. See Topologies, Lemmas 33.7.4, 33.6.4, 33.5.4, 33.4.4, and 33.3.3. □

Finally, we come to our definition of the sites we will be working with. This is actually somewhat involved since, contrary to what happens in [AGV71], we do not want to choose a universe. Instead we pick a “partial universe” (which just means a suitably large set), and consider all schemes contained in this set. Of course we make sure that our favorite base scheme S is contained in the partial universe. Having picked the underlying category we pick a suitably large set of τ -coverings which turns this into a site. The details are in the chapter on topologies on schemes; there is a lot of freedom in the choices made, but in the end the actual choices made will not affect the $\acute{e}tale$ (or other) cohomology of S (just as in [AGV71] the actual choice of universe doesn’t matter at the end). Moreover, the way the material is written the reader who is happy using strongly inaccessible cardinals (i.e., universes) can do so as a substitute.

Definition 44.20.4. Let S be a scheme. Let $\tau \in \{fppf, syntomic, smooth, \acute{e}tale, Zariski\}$.

- (1) A *big τ -site of S* is any of the sites $(Sch/S)_\tau$ constructed as explained above and in more detail in Topologies, Definitions 33.7.8, 33.6.8, 33.5.8, 33.4.8, and 33.3.7.
- (2) If $\tau \in \{\acute{e}tale, Zariski\}$, then the *small τ -site of S* is the full subcategory S_τ of $(Sch/S)_\tau$ whose objects are schemes T over S whose structure morphism $T \rightarrow S$ is $\acute{e}tale$, resp. an open immersion. A covering in S_τ is a covering $\{U_i \rightarrow U\}$ in $(Sch/S)_\tau$ such that U is an object of S_τ .

The underlying category of the site $(Sch/S)_\tau$ has reasonable “closure” properties, i.e., given a scheme T in it any locally closed subscheme of T is isomorphic to an

object of $(Sch/S)_\tau$. Other such closure properties are: closed under fibre products of schemes, taking countable disjoint unions, taking finite type schemes over a given scheme, given an affine scheme $\text{Spec}(R)$ one can complete, localize, or take the quotient of R by an ideal while staying inside the category, etc. On the other hand, for example arbitrary disjoint unions of schemes in $(Sch/S)_\tau$ will take you outside of it. Also note that, given an object T of $(Sch/S)_\tau$ there will exist τ -coverings $\{T_i \rightarrow T\}_{i \in I}$ (as in Definition 44.20.1) which are not coverings in $(Sch/S)_\tau$ for example because the schemes T_i are not objects of the category $(Sch/S)_\tau$. But our choice of the sites $(Sch/S)_\tau$ is such that there always does exist a covering $\{U_j \rightarrow T\}_{j \in J}$ of $(Sch/S)_\tau$ which refines the covering $\{T_i \rightarrow T\}_{i \in I}$, see Topologies, Lemmas 33.7.7, 33.6.7, 33.5.7, 33.4.7, and 33.3.6. We will mostly ignore these issues in this chapter.

If \mathcal{F} is a sheaf on $(Sch/S)_\tau$ or S_τ , then we denote

$$H_\tau^p(U, \mathcal{F}), \text{ in particular } H_\tau^p(S, \mathcal{F})$$

the cohomology groups of \mathcal{F} over the object U of the site, see Section 44.14. Thus we have $H_{fppf}^p(S, \mathcal{F})$, $H_{syntomic}^p(S, \mathcal{F})$, $H_{smooth}^p(S, \mathcal{F})$, $H_{\acute{e}tale}^p(S, \mathcal{F})$, and $H_{Zar}^p(S, \mathcal{F})$. The last two are potentially ambiguous since they might refer to either the big or small étale or Zariski site. However, this ambiguity is harmless by the following lemma.

Lemma 44.20.5. *Let $\tau \in \{\acute{e}tale, Zariski\}$. If \mathcal{F} is an abelian sheaf defined on $(Sch/S)_\tau$, then the cohomology groups of \mathcal{F} over S agree with the cohomology groups of $\mathcal{F}|_{S_\tau}$ over S .*

Proof. By Topologies, Lemmas 33.3.13 and 33.4.13 the functors $S_\tau \rightarrow (Sch/S)_\tau$ satisfy the hypotheses of Sites, Lemma 7.20.8. Hence our lemma follows from Cohomology on Sites, Lemma 21.8.2. \square

For completeness we state and prove the invariance under choice of partial universe of the cohomology groups we are considering. We will prove invariance of the small étale topos in Lemma 44.21.3 below. For notation and terminology used in this lemma we refer to Topologies, Section 33.10.

Lemma 44.20.6. *Let $\tau \in \{fppf, syntomic, smooth, \acute{e}tale, Zariski\}$. Let S be a scheme. Let $(Sch/S)_\tau$ and $(Sch'/S)_\tau$ be two big τ -sites of S , and assume that the first is contained in the second. In this case*

- (1) *for any abelian sheaf \mathcal{F}' defined on $(Sch'/S)_\tau$ and any object U of $(Sch/S)_\tau$ we have*

$$H_\tau^p(U, \mathcal{F}'|_{(Sch/S)_\tau}) = H_\tau^p(U, \mathcal{F}')$$

In words: the cohomology of \mathcal{F}' over U computed in the bigger site agrees with the cohomology of \mathcal{F}' restricted to the smaller site over U .

- (2) *for any abelian sheaf \mathcal{F} on $(Sch/S)_\tau$ there is an abelian sheaf \mathcal{F}' on $(Sch'/S)_\tau$ whose restriction to $(Sch/S)_\tau$ is isomorphic to \mathcal{F} .*

Proof. By Topologies, Lemma 33.10.2 the inclusion functor $(Sch/S)_\tau \rightarrow (Sch'/S)_\tau$ satisfies the assumptions of Sites, Lemma 7.20.8. This implies (2) and (1) follows from Cohomology on Sites, Lemma 21.8.2. \square

44.21. The étale topos

A *topos* is the category of sheaves of sets on a site, see Sites, Definition 7.16.1. Hence it is customary to refer to the use the phrase “étale topos of a scheme” to refer to the category of sheaves on the small étale site of a scheme. Here is the formal definition.

Definition 44.21.1. Let S be a scheme.

- (1) The *étale topos*, or the *small étale topos* of S is the category $Sh(S_{\text{étale}})$ of sheaves of sets on the small étale site of S .
- (2) The *Zariski topos*, or the *small Zariski topos* of S is the category $Sh(S_{\text{Zar}})$ of sheaves of sets on the small Zariski site of S .
- (3) For $\tau \in \{fppf, syntomic, smooth, \text{étale}, Zariski\}$ a *big τ -topos* is the category of sheaves of set on a big τ -topos of S .

Note that the small Zariski topos of S is simply the category of sheaves of sets on the underlying topological space of S , see Topologies, Lemma 33.3.11. Whereas the small étale topos does not depend on the choices made in the construction of the small étale site, in general the big topoi do depend on those choices.

Here is a lemma, which is one of many possible lemmas expressing the fact that it doesn't matter too much which site we choose to define the small étale topos of a scheme.

Lemma 44.21.2. *Let S be a scheme. Let $S_{\text{affine,étale}}$ denote the full subcategory of $S_{\text{étale}}$ whose objects are those $U/S \in \text{Ob}(S_{\text{étale}})$ with U affine. A covering of $S_{\text{affine,étale}}$ will be a standard étale covering, see Topologies, Definition 33.4.5. Then restriction*

$$\mathcal{F} \longmapsto \mathcal{F}|_{S_{\text{affine,étale}}}$$

defines an equivalence of topoi $Sh(S_{\text{étale}}) \cong Sh(S_{\text{affine,étale}})$.

Proof. This you can show directly from the definitions, and is a good exercise. But it also follows immediately from Sites, Lemma 7.28.1 by checking that the inclusion functor $S_{\text{affine,étale}} \rightarrow S_{\text{étale}}$ is a special cocontinuous functor (see Sites, Definition 7.28.2). \square

Lemma 44.21.3. *Let S be a scheme. The étale topos of S is independent (up to canonical equivalence) of the construction of the small étale site in Definition 44.20.4.*

Proof. We have to show, given two big étale sites $Sch_{\text{étale}}$ and $Sch'_{\text{étale}}$ containing S , then $Sh(S_{\text{étale}}) \cong Sh(S'_{\text{étale}})$ with obvious notation. By Topologies, Lemma 33.10.1 we may assume $Sch_{\text{étale}} \subset Sch'_{\text{étale}}$. By Sets, Lemma 3.9.9 any affine scheme étale over S is isomorphic to an object of both $Sch_{\text{étale}}$ and $Sch'_{\text{étale}}$. Thus the induced functor $S_{\text{affine,étale}} \rightarrow S'_{\text{affine,étale}}$ is an equivalence. Moreover, it is clear that both this functor and a quasi-inverse map transform standard étale coverings into standard étale coverings. Hence the result follows from Lemma 44.21.2. \square

44.22. Cohomology of quasi-coherent sheaves

We start with a simple lemma (which holds in greater generality than stated). It says that the Čech complex of a standard covering is equal to the Čech complex of an fpqc covering of the form $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$ with $A \rightarrow B$ faithfully flat.

Lemma 44.22.1. *Let $\tau \in \{fppf, \text{syntomic}, \text{smooth}, \text{étale}, \text{Zariski}\}$. Let S be a scheme. Let \mathcal{F} be an abelian sheaf on $(\text{Sch}/S)_\tau$, or on S_τ in case $\tau = \text{étale}$, and let $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ be a standard τ -covering of this site. Let $V = \coprod_{i \in I} U_i$. Then*

- (1) V is an affine scheme,
- (2) $\mathcal{V} = \{V \rightarrow U\}$ is a τ -covering and an fpqc covering,
- (3) the Čech complexes $\check{C}^\bullet(\mathcal{U}, \mathcal{F})$ and $\check{C}^\bullet(\mathcal{V}, \mathcal{F})$ agree.

Proof. As the covering is a standard τ -covering each of the schemes U_i is affine and I is a finite set. Hence V is an affine scheme. It is clear that $V \rightarrow U$ is flat and surjective, hence \mathcal{V} is an fpqc covering, see Example 44.15.3. Note that \mathcal{U} is a refinement of \mathcal{V} and hence there is a map of Čech complexes $\check{C}^\bullet(\mathcal{V}, \mathcal{F}) \rightarrow \check{C}^\bullet(\mathcal{U}, \mathcal{F})$, see Cohomology on Sites, Equation (21.9.2.1). Next, we observe that if $T = \coprod_{j \in J} T_j$ is a disjoint union of schemes in the site on which \mathcal{F} is defined then the family of morphisms with fixed target $\{T_j \rightarrow T\}_{j \in J}$ is a Zariski covering, and so

$$(44.22.1.1) \quad \mathcal{F}(T) = \mathcal{F}\left(\coprod_{j \in J} T_j\right) = \prod_{j \in J} \mathcal{F}(T_j)$$

by the sheaf condition of \mathcal{F} . This implies the map of Čech complexes above is an isomorphism in each degree because

$$V \times_U \dots \times_U V = \prod_{i_0, \dots, i_p} U_{i_0} \times_U \dots \times_U U_{i_p}$$

as schemes. □

Note that Equality (44.22.1.1) is false for a general presheaf. Even for sheaves it does not hold on any site, since coproducts may not lead to coverings, and may not be disjoint. But it does for all the usual ones (at least all the ones we will study).

Remark 44.22.2. In the statement of Lemma 44.22.1 the covering \mathcal{U} is a refinement of \mathcal{V} but not the other way around. Coverings of the form $\{V \rightarrow U\}$ do not form an initial subcategory of the category of all coverings of U . Yet it is still true that we can compute Čech cohomology $H^n(U, \mathcal{F})$ (which is defined as the colimit over the opposite of the category of coverings \mathcal{U} of U of the Čech cohomology groups of \mathcal{F} with respect to \mathcal{U}) in terms of the coverings $\{V \rightarrow U\}$. We will formulate a precise lemma (it only works for sheaves) and add it here if we ever need it.

Lemma 44.22.3 (Locality of cohomology). *Let \mathcal{C} be a site, \mathcal{F} an abelian sheaf on \mathcal{C} , U an object of \mathcal{C} , $p > 0$ an integer and $\xi \in H^p(U, \mathcal{F})$. Then there exists a covering $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ of U in \mathcal{C} such that $\xi|_{U_i} = 0$ for all $i \in I$.*

Proof. Choose an injective resolution $\mathcal{F} \rightarrow \mathcal{I}^\bullet$. Then ξ is represented by a cocycle $\tilde{\xi} \in \mathcal{I}^p(U)$ with $d^p(\tilde{\xi}) = 0$. By assumption, the sequence $\mathcal{I}^{p-1} \rightarrow \mathcal{I}^p \rightarrow \mathcal{I}^{p+1}$ is exact in $\text{Ab}(\mathcal{C})$, which means that there exists a covering $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ such that $\tilde{\xi}|_{U_i} = d^{p-1}(\xi_i)$ for some $\xi_i \in \mathcal{I}^{p-1}(U_i)$. Since the cohomology class $\xi|_{U_i}$ is represented by the cocycle $\tilde{\xi}|_{U_i}$ which is a coboundary, it vanishes. For more details see Cohomology on Sites, Lemma 21.8.3. □

Theorem 44.22.4. *Let S be a scheme and \mathcal{F} a quasi-coherent \mathcal{O}_S -module. Let \mathcal{C} be either $(\text{Sch}/S)_\tau$ for $\tau \in \{fppf, \text{syntomic}, \text{smooth}, \text{étale}, \text{Zariski}\}$ or $S_{\text{étale}}$. Then*

$$H^p(S, \mathcal{F}) = H^p_\tau(S, \mathcal{F}^a)$$

for all $p \geq 0$ where

- (1) the left hand side indicates the usual cohomology of the sheaf \mathcal{F} on the underlying topological space of the scheme S , and
- (2) the right hand side indicates cohomology of the abelian sheaf \mathcal{F}^a (see Proposition 44.17.1) on the site \mathcal{C} .

Proof. We are going to show that $H^p(U, f^*\mathcal{F}) = H^p_\tau(U, \mathcal{F}^a)$ for any object $f : U \rightarrow S$ of the site \mathcal{C} . The result is true for $p = 0$ by the sheaf property.

Assume that U is affine. Then we want to prove that $H^p_\tau(U, \mathcal{F}^a) = 0$ for all $p > 0$. We use induction on p .

$p = 1$ Pick $\xi \in H^1_\tau(U, \mathcal{F}^a)$. By Lemma 44.22.3, there exists an fpqc covering $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ such that $\xi|_{U_i} = 0$ for all $i \in I$. Up to refining \mathcal{U} , we may assume that \mathcal{U} is a standard τ -covering. Applying the spectral sequence of Theorem 44.19.2, we see that ξ comes from a cohomology class $\check{\xi} \in \check{H}^1(\mathcal{U}, \mathcal{F}^a)$. Consider the covering $\mathcal{V} = \{\coprod_{i \in I} U_i \rightarrow U\}$. By Lemma 44.22.1, $\check{H}^\bullet(\mathcal{U}, \mathcal{F}^a) = \check{H}^\bullet(\mathcal{V}, \mathcal{F}^a)$. On the other hand, since \mathcal{V} is a covering of the form $\{\text{Spec}(B) \rightarrow \text{Spec}(A)\}$ and $f^*\mathcal{F} = \widetilde{M}$ for some A -module M , we see the Čech complex $\check{C}^\bullet(\mathcal{V}, \mathcal{F})$ is none other than the complex $(B/A)_\bullet \otimes_A M$. Now by Lemma 44.16.4, $H^p((B/A)_\bullet \otimes_A M) = 0$ for $p > 0$, hence $\check{\xi} = 0$ and so $\xi = 0$.

$p > 1$ Pick $\xi \in H^p_\tau(U, \mathcal{F}^a)$. By Lemma 44.22.3, there exists an fpqc covering $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ such that $\xi|_{U_i} = 0$ for all $i \in I$. Up to refining \mathcal{U} , we may assume that \mathcal{U} is a standard τ -covering. We apply the spectral sequence of Theorem 44.19.2. Observe that the intersections $U_{i_0} \times_U \dots \times_U U_{i_p}$ are affine, so that by induction hypothesis the cohomology groups

$$E_2^{p,q} = \check{H}^p(\mathcal{U}, \underline{H}^q(\mathcal{F}^a))$$

vanish for all $0 < q < p$. We see that ξ must come from a $\check{\xi} \in \check{H}^p(\mathcal{U}, \mathcal{F}^a)$. Replacing \mathcal{U} with the covering \mathcal{V} containing only one morphism and using Lemma 44.16.4 again, we see that the Čech cohomology class $\check{\xi}$ must be zero, hence $\xi = 0$.

Next, assume that U is separated. Choose an affine open covering $U = \bigcup_{i \in I} U_i$ of U . The family $\mathcal{U} = \{U_i \rightarrow U\}_{i \in I}$ is then an fpqc covering, and all the intersections $U_{i_0} \times_S \dots \times_S U_{i_p}$ are affine since U is separated. So all rows of the spectral sequence of Theorem 44.19.2 are zero, except the zeroth row. Therefore

$$H^p_\tau(S, \mathcal{F}^a) = \check{H}^p(\mathcal{U}, \mathcal{F}^a) = \check{H}^p(\mathcal{U}, \mathcal{F}) = H^p(S, \mathcal{F})$$

where the last equality results from standard scheme theory, see Cohomology of Schemes, Lemma 29.2.5.

The general case is technical and (to extend the proof as given here) requires a discussion about maps of spectral sequences, so we won't treat it. It follows from Descent, Proposition 34.7.10 (whose proof takes a slightly different approach) combined with Cohomology on Sites, Lemma 21.8.1. □

Remark 44.22.5. Comment on Theorem 44.22.4. Since S is a final object in the category \mathcal{C} , the cohomology groups on the right-hand side are merely the right derived functors of the global sections functor. In fact the proof shows that $H^p(U, f^*\mathcal{F}) = H^p_\tau(U, \mathcal{F}^a)$ for any object $f : U \rightarrow S$ of the site \mathcal{C} .

44.23. Examples of sheaves

Let S and τ be as in Section 44.20. We have already seen that any representable presheaf is a sheaf on $(Sch/S)_\tau$ or S_τ , see Lemma 44.15.8 and Remark 44.15.9. Here are some special cases.

Definition 44.23.1. On any of the sites $(Sch/S)_\tau$ or S_τ of Section 44.20.

- (1) The sheaf $T \mapsto \Gamma(T, \mathcal{O}_T)$ is denoted \mathcal{O}_S , or \mathbf{G}_a , or $\mathbf{G}_{a,S}$ if we want to indicate the base scheme.
- (2) Similarly, the sheaf $T \mapsto \Gamma(T, \mathcal{O}_T^*)$ is denoted \mathcal{O}_S^* , or \mathbf{G}_m , or $\mathbf{G}_{m,S}$ if we want to indicate the base scheme.
- (3) The *constant sheaf* $\mathbf{Z}/n\mathbf{Z}$ on any site is the sheafification of the constant presheaf $U \mapsto \mathbf{Z}/n\mathbf{Z}$.

The first is a sheaf by Theorem 44.17.4 for example. The second is a sub presheaf of the first, which is easily seen to be a sheaf itself. The third is a sheaf by definition. Note that each of these sheaves is representable. The first and second by the schemes $\mathbf{G}_{a,S}$ and $\mathbf{G}_{m,S}$, see Groupoids, Section 38.4. The third by the finite étale group scheme $\mathbf{Z}/n\mathbf{Z}_S$ sometimes denoted $(\mathbf{Z}/n\mathbf{Z})_S$ which is just n copies of S endowed with the obvious group scheme structure over S , see Groupoids, Example 38.5.6 and the following remark.

Remark 44.23.2. Let G be an abstract group. On any of the sites $(Sch/S)_\tau$ or S_τ of Section 44.20 the sheafification \underline{G} of the constant presheaf associated to G in the *Zariski topology* of the site already gives

$$\Gamma(U, \underline{G}) = \{\text{Zariski locally constant maps } U \rightarrow G\}$$

This Zariski sheaf is representable by the group scheme G_S according to Groupoids, Example 38.5.6. By Lemma 44.15.8 any representable presheaf satisfies the sheaf condition for the τ -topology as well, and hence we conclude that the Zariski sheafification \underline{G} above is also the τ -sheafification.

Definition 44.23.3. Let S be a scheme. The *structure sheaf* of S is the sheaf of rings \mathcal{O}_S on any of the sites S_{Zar} , $S_{\acute{e}tale}$, or $(Sch/S)_\tau$ discussed above.

If there is some possible confusion as to which site we are working on then we will indicate this by using indices. For example we may use $\mathcal{O}_{S_{\acute{e}tale}}$ to stress the fact that we are working on the small étale site of S .

Remark 44.23.4. In the terminology introduced above a special case of Theorem 44.22.4 is

$$H_{fppf}^p(X, \mathbf{G}_a) = H_{\acute{e}tale}^p(X, \mathbf{G}_a) = H_{Zar}^p(X, \mathbf{G}_a) = H^p(X, \mathcal{O}_X)$$

for all $p \geq 0$. Moreover, we could use the notation $H_{fppf}^p(X, \mathcal{O}_X)$ to indicate the cohomology of the structure sheaf on the big fppf site of X .

44.24. Picard groups

The following theorem is sometimes called “Hilbert 90”.

Theorem 44.24.1. *For any scheme X we have canonical identifications*

$$\begin{aligned} H_{fppf}^1(X, \mathbf{G}_m) &= H_{syntomic}^1(X, \mathbf{G}_m) \\ &= H_{smooth}^1(X, \mathbf{G}_m) \\ &= H_{\acute{e}tale}^1(X, \mathbf{G}_m) \\ &= H_{Zar}^1(X, \mathbf{G}_m) \\ &= \text{Pic}(X) \\ &= H^1(X, \mathcal{O}_X^*) \end{aligned}$$

Proof. Let τ be one of the topologies considered in Section 44.20. By Cohomology on Sites, Lemma 21.7.1 we see that $H_{\tau}^1(X, \mathbf{G}_m) = H_{\tau}^1(X, \mathcal{O}_{\tau}^*) = \text{Pic}(\mathcal{O}_{\tau})$ where \mathcal{O}_{τ} is the structure sheaf of the site $(Sch/X)_{\tau}$. Now an invertible \mathcal{O}_{τ} -module is a quasi-coherent \mathcal{O}_{τ} -module. By Theorem 44.17.4 or the more precise Descent, Proposition 34.7.11 we see that $\text{Pic}(\mathcal{O}_{\tau}) = \text{Pic}(X)$. The last equality is proved in the same way. \square

44.25. The étale site

At this point we start exploring the étale site of a scheme in more detail. As a first step we discuss a little the notion of an étale morphism.

44.26. Étale morphisms

For more details, see Morphisms, Section 28.37 for the formal definition and Étale Morphisms, Sections 40.11, 40.12, 40.13, 40.14, 40.16, and 40.19 for a survey of interesting properties of étale morphisms.

Recall that an algebra A over an algebraically closed field k is *smooth* if it is of finite type and the module of differentials $\Omega_{A/k}$ is finite locally free of rank equal to the dimension. A scheme X over k is *smooth* over k if it is locally of finite type and each affine open is the spectrum of a smooth k -algebra. If k is not algebraically closed then an A -algebra is said to be a smooth k -algebra if $A \otimes_k \bar{k}$ is a smooth \bar{k} -algebra. A ring map $A \rightarrow B$ is smooth if it is flat, finitely presented, and for all primes $\mathfrak{p} \subset A$ the fibre ring $\kappa(\mathfrak{p}) \otimes_A B$ is smooth over the residue field $\kappa(\mathfrak{p})$. More generally, a morphism of schemes is *smooth* if it is flat, locally of finite presentation, and the geometric fibers are smooth.

For these facts please see Morphisms, Section 28.35. Using this we may define an étale morphism as follows.

Definition 44.26.1. A morphism of schemes is *étale* if it is smooth of relative dimension 0.

In particular, a morphism of schemes $X \rightarrow S$ is étale if it is smooth and $\Omega_{X/S} = 0$.

Proposition 44.26.2. *Facts on étale morphisms.*

- (1) *Let k be a field. A morphism of schemes $U \rightarrow \text{Spec}(k)$ is étale if and only if $U \cong \coprod_{i \in I} \text{Spec}(k_i)$ such that for each $i \in I$ the ring k_i is a field which is a finite separable extension of k .*
- (2) *Let $\varphi : U \rightarrow S$ be a morphism of schemes. The following conditions are equivalent:*
 - (a) *φ is étale,*

- (b) φ is locally finitely presented, flat, and all its fibres are étale,
- (c) φ is flat, unramified and locally of finite presentation.
- (3) A ring map $A \rightarrow B$ is étale if and only if $B \cong A[x_1, \dots, x_n]/(f_1, \dots, f_n)$ such that $\Delta = \det \left(\frac{\partial f_i}{\partial x_j} \right)$ is invertible in B .
- (4) The base change of an étale morphism is étale.
- (5) Compositions of étale morphisms are étale.
- (6) Fibre products and products of étale morphisms are étale.
- (7) An étale morphism has relative dimension 0.
- (8) Let $Y \rightarrow X$ be an étale morphism. If X is reduced (respectively regular) then so is Y .
- (9) Étale morphisms are open.
- (10) If $X \rightarrow S$ and $Y \rightarrow S$ are étale, then any S -morphism $X \rightarrow Y$ is also étale.

Proof. We have proved these facts (and more) in the preceding chapters. Here is a list of references: (1) Morphisms, Lemma 28.37.7. (2) Morphisms, Lemmas 28.37.8 and 28.37.16. (3) Algebra, Lemma 10.138.2. (4) Morphisms, Lemma 28.37.4. (5) Morphisms, Lemma 28.37.3. (6) Follows formally from (4) and (5). (7) Morphisms, Lemmas 28.37.6 and 28.30.5. (8) See Algebra, Lemmas 10.151.6 and 10.151.5, see also more results of this kind in Étale Morphisms, Section 40.19. (9) See Morphisms, Lemma 28.26.9 and 28.37.12. (10) See Morphisms, Lemma 28.37.18. \square

Definition 44.26.3. A ring map $A \rightarrow B$ is called *standard étale* if $B \cong (A[t]/(f))_g$ with $f, g \in A[t]$, with f monic, and df/dt invertible in B .

It is true that a standard étale ring map is étale. Namely, suppose that $B = (A[t]/(f))_g$ with $f, g \in A[t]$, with f monic, and df/dt invertible in B . Then $A[t]/(f)$ is a finite free A -module of rank equal to the degree of the monic polynomial f . Hence B , as a localization of this free algebra is finitely presented and flat over A . To finish the proof that B is étale it suffices to show that the fibre rings

$$\kappa(\mathfrak{p}) \otimes_A B \cong \kappa(\mathfrak{p}) \otimes_A (A[t]/(f))_g \cong \kappa(\mathfrak{p})[t, 1/\bar{g}]/(\bar{f})$$

are finite products of finite separable field extensions. Here $\bar{f}, \bar{g} \in \kappa(\mathfrak{p})[t]$ are the images of f and g . Let

$$\bar{f} = \bar{f}_1 \cdots \bar{f}_a \bar{f}_{a+1}^{e_1} \cdots \bar{f}_{a+b}^{e_b}$$

be the factorization of \bar{f} into powers of pairwise distinct irreducible monic factors \bar{f}_i with $e_1, \dots, e_b > 0$. By assumption $d\bar{f}/dt$ is invertible in $\kappa(\mathfrak{p})[t, 1/\bar{g}]$. Hence we see that at least all the $\bar{f}_i, i > a$ are invertible. We conclude that

$$\kappa(\mathfrak{p})[t, 1/\bar{g}]/(\bar{f}) \cong \prod_{i \in I} \kappa(\mathfrak{p})[t]/(\bar{f}_i)$$

where $I \subset \{1, \dots, a\}$ is the subset of indices i such that \bar{f}_i does not divide \bar{g} . Moreover, the image of $d\bar{f}/dt$ in the factor $\kappa(\mathfrak{p})[t]/(\bar{f}_i)$ is clearly equal to a unit times $d\bar{f}_i/dt$. Hence we conclude that $\kappa_i = \kappa(\mathfrak{p})[t]/(\bar{f}_i)$ is a finite field extension of $\kappa(\mathfrak{p})$ generated by one element whose minimal polynomial is separable, i.e., the field extension $\kappa(\mathfrak{p}) \subset \kappa_i$ is finite separable as desired.

It turns out that any étale ring map is locally standard étale. To formulate this we introduce the following notation. A ring map $A \rightarrow B$ is *étale at a prime* \mathfrak{q} of B if there exists $h \in B, h \notin \mathfrak{q}$ such that $A \rightarrow B_h$ is étale. Here is the result.

Theorem 44.26.4. *A ring map $A \rightarrow B$ is étale at a prime \mathfrak{q} if and only if there exists $g \in B$, $g \notin \mathfrak{q}$ such that B_g is standard étale over A .*

Proof. See Algebra, Proposition 10.138.17. □

44.27. Étale coverings

We recall the definition.

Definition 44.27.1. An *étale covering* of a scheme U is a family of morphisms of schemes $\{\varphi_i : U_i \rightarrow U\}_{i \in I}$ such that

- (1) each φ_i is an étale morphism,
- (2) the U_i cover U , i.e., $U = \bigcup_{i \in I} \varphi_i(U_i)$.

Lemma 44.27.2. *Any étale covering is an fpqc covering.*

Proof. (See also Topologies, Lemma 33.8.6.) Let $\{\varphi_i : U_i \rightarrow U\}_{i \in I}$ be an étale covering. Since an étale morphism is flat, and the elements of the covering should cover its target, the property fp (faithfully flat) is satisfied. To check the property qc (quasi-compact), let $V \subset U$ be an affine open, and write $\varphi_i^{-1} = \bigcup_{j \in J_i} V_{ij}$ for some affine opens $V_{ij} \subset U_i$. Since φ_i is open (as étale morphisms are open), we see that $V = \bigcup_{i \in I} \bigcup_{j \in J_i} \varphi_i(V_{ij})$ is an open covering of V . Further, since V is quasi-compact, this covering has a finite refinement. □

So any statement which is true for fpqc coverings remains true *a fortiori* for étale coverings. For instance, the étale site is subcanonical.

Definition 44.27.3. (For more details see Section 44.20, or Topologies, Section 33.4.) Let S be a scheme. The *big étale site over S* is the site $(Sch/S)_{\acute{e}t\grave{a}l\grave{e}}$, see Definition 44.20.4. The *small étale site over S* is the site $S_{\acute{e}t\grave{a}l\grave{e}}$, see Definition 44.20.4. We define similarly the *big* and *small Zariski sites* on S , denoted $(Sch/S)_{Zar}$ and S_{Zar} .

Loosely speaking the big étale site of S is made up out of schemes over S and coverings the étale coverings. The small étale site of S is made up out of schemes étale over S with coverings the étale coverings. Actually any morphism between objects of $S_{\acute{e}t\grave{a}l\grave{e}}$ is étale, in virtue of Proposition 44.26.2, hence to check that $\{U_i \rightarrow U\}_{i \in I}$ in $S_{\acute{e}t\grave{a}l\grave{e}}$ is a covering it suffices to check that $\coprod U_i \rightarrow U$ is surjective.

The small étale site has fewer objects than the big étale site, it contains only the “opens” of the étale topology on S . It is a full subcategory of the big étale site, and its topology is induced from the topology on the big site. Hence it is true that the restriction functor from the big étale site to the small one is exact and maps injectives to injectives. This has the following consequence.

Proposition 44.27.4. *Let S be a scheme and \mathcal{F} an abelian sheaf on $(Sch/S)_{\acute{e}t\grave{a}l\grave{e}}$. Then $\mathcal{F}|_{S_{\acute{e}t\grave{a}l\grave{e}}}$ is a sheaf on $S_{\acute{e}t\grave{a}l\grave{e}}$ and*

$$H_{\acute{e}t\grave{a}l\grave{e}}^p(S, \mathcal{F}|_{S_{\acute{e}t\grave{a}l\grave{e}}}) = H_{\acute{e}t\grave{a}l\grave{e}}^p(S, \mathcal{F})$$

for all $p \geq 0$.

Proof. This is a special case of Lemma 44.20.5. □

In accordance with the general notation introduced in Section 44.20 we write $H_{\acute{e}t\grave{a}l\grave{e}}^p(S, \mathcal{F})$ for the above cohomology group.

44.28. Kummer theory

Let $n \in \mathbf{N}$ and consider the functor μ_n defined by

$$\begin{array}{ccc} Sch^{opp} & \longrightarrow & Ab \\ S & \longmapsto & \mu_n(S) = \{t \in \Gamma(S, \mathcal{O}_S^*) \mid t^n = 1\}. \end{array}$$

By Groupoids, Example 38.5.2 this is a representable functor, and the scheme representing it is denoted μ_n also. By Lemma 44.15.8 this functor satisfies the sheaf condition for the fpqc topology (in particular, it is also satisfies the sheaf condition for the étale, Zariski, etc topology).

Lemma 44.28.1. *If $n \in \mathcal{O}_S^*$ then*

$$0 \rightarrow \mu_{n,S} \rightarrow \mathbf{G}_{m,S} \xrightarrow{(\cdot)^n} \mathbf{G}_{m,S} \rightarrow 0$$

is a short exact sequence of sheaves on both the small and big étale site of S .

Proof. By definition the sheaf $\mu_{n,S}$ is the kernel of the map $(\cdot)^n$. Hence it suffices to show that the last map is surjective. Let U be a scheme over S . Let $f \in \mathbf{G}_m(U) = \Gamma(U, \mathcal{O}_U^*)$. We need to show that we can find an étale cover of U over the members of which the restriction of f is an n th power. Set

$$U' = \underline{\text{Spec}}_U(\mathcal{O}_U[T]/(T^n - f)) \xrightarrow{\pi} U.$$

(See Constructions, Section 26.3 or 26.4 for a discussion of the relative spectrum.) Let $\text{Spec}(A) \subset U$ be an affine open, and say $f|_{\text{Spec}(A)}$ corresponds to the unit $a \in A^*$. Then $\pi^{-1}(\text{Spec}(A)) = \text{Spec}(B)$ with $B = A[T]/(T^n - a)$. The ring map $A \rightarrow B$ is finite free of rank n , hence it is faithfully flat, and hence we conclude that $\text{Spec}(B) \rightarrow \text{Spec}(A)$ is surjective. Since this holds for every affine open in U we conclude that π is surjective. In addition, n and T^{n-1} are invertible in B , so $nT^{n-1} \in B^*$ and the ring map $A \rightarrow B$ is standard étale, in particular étale. Since this holds for every affine open of U we conclude that π is étale. Hence $\mathcal{U} = \{\pi : U' \rightarrow U\}$ is an étale covering. Moreover, $f|_{U'} = (f')^n$ where f' is the class of T in $\Gamma(U', \mathcal{O}_{U'}^*)$, so \mathcal{U} has the desired property. \square

Remark 44.28.2. Lemma 44.28.1 is false when “étale” is replaced with “Zariski”. Since the étale topology is coarser than the smooth topology, see Topologies, Lemma 33.5.2 it follows that the sequence is also exact in the smooth topology.

By Theorem 44.24.1 and Lemma 44.28.1 and general properties of cohomology we obtain the long exact cohomology sequence

$$\begin{array}{ccccccc} 0 & \longrightarrow & H_{\text{étale}}^0(S, \mu_{n,S}) & \longrightarrow & \Gamma(S, \mathcal{O}_S^*) & \xrightarrow{(\cdot)^n} & \Gamma(S, \mathcal{O}_S^*) \\ & & & & & \searrow & \\ & & H_{\text{étale}}^1(S, \mu_{n,S}) & \longrightarrow & \text{Pic}(S) & \xrightarrow{(\cdot)^n} & \text{Pic}(S) \\ & & & & & \searrow & \\ & & H_{\text{étale}}^2(S, \mu_{n,S}) & \longrightarrow & \dots & & \end{array}$$

at least if n is invertible on S . When n is not invertible on S we can apply the following lemma.

Lemma 44.28.3. *For any $n \in \mathbf{N}$ the sequence*

$$0 \rightarrow \mu_{n,S} \rightarrow \mathbf{G}_{m,S} \xrightarrow{(\cdot)^n} \mathbf{G}_{m,S} \rightarrow 0$$

is a short exact sequence of sheaves on the site $(Sch/S)_{fppf}$ and $(Sch/S)_{syntomic}$.

Proof. By definition the sheaf $\mu_{n,S}$ is the kernel of the map $(\cdot)^n$. Hence it suffices to show that the last map is surjective. Since the syntomic topology is stronger than the fppf topology, see Topologies, Lemma 33.7.2, it suffices to prove this for the syntomic topology. Let U be a scheme over S . Let $f \in \mathbf{G}_m(U) = \Gamma(U, \mathcal{O}_U^*)$. We need to show that we can find a syntomic cover of U over the members of which the restriction of f is an n th power. Set

$$U' = \underline{\text{Spec}}_U(\mathcal{O}_U[T]/(T^n - f)) \xrightarrow{\pi} U.$$

(See Constructions, Section 26.3 or 26.4 for a discussion of the relative spectrum.) Let $\text{Spec}(A) \subset U$ be an affine open, and say $f|_{\text{Spec}(A)}$ corresponds to the unit $a \in A^*$. Then $\pi^{-1}(\text{Spec}(A)) = \text{Spec}(B)$ with $B = A[T]/(T^n - a)$. The ring map $A \rightarrow B$ is finite free of rank n , hence it is faithfully flat, and hence we conclude that $\text{Spec}(B) \rightarrow \text{Spec}(A)$ is surjective. Since this holds for every affine open in U we conclude that π is surjective. In addition, B is a global relative complete intersection over A , so the ring map $A \rightarrow B$ is standard syntomic, in particular syntomic. Since this holds for every affine open of U we conclude that π is syntomic. Hence $\mathcal{U} = \{\pi : U' \rightarrow U\}$ is a syntomic covering. Moreover, $f|_{U'} = (f')^n$ where f' is the class of T in $\Gamma(U', \mathcal{O}_{U'}^*)$, so \mathcal{U} has the desired property. \square

Remark 44.28.4. Lemma 44.28.3 is false for the smooth, étale, or Zariski topology.

By Theorem 44.24.1 and Lemma 44.28.3 and general properties of cohomology we obtain the long exact cohomology sequence

$$\begin{array}{ccccccc} 0 & \longrightarrow & H_{fppf}^0(S, \mu_{n,S}) & \longrightarrow & \Gamma(S, \mathcal{O}_S^*) & \xrightarrow{(\cdot)^n} & \Gamma(S, \mathcal{O}_S^*) \\ & & & & \swarrow & & \\ & & H_{fppf}^1(S, \mu_{n,S}) & \longrightarrow & \text{Pic}(S) & \xrightarrow{(\cdot)^n} & \text{Pic}(S) \\ & & & & \swarrow & & \\ & & H_{fppf}^2(S, \mu_{n,S}) & \longrightarrow & \dots & & \end{array}$$

for any scheme S and any integer n . Of course there is a similar sequence with syntomic cohomology.

Let $n \in \mathbf{N}$ and let S be any scheme. There is another more direct way to describe the first cohomology group with values in μ_n . Consider pairs (\mathcal{L}, α) where \mathcal{L} is an invertible sheaf on S and $\alpha : \mathcal{L}^{\otimes n} \rightarrow \mathcal{O}_S$ is a trivialization of the n th tensor power of \mathcal{L} . Let (\mathcal{L}', α') be a second such pair. An isomorphism $\varphi : (\mathcal{L}, \alpha) \rightarrow (\mathcal{L}', \alpha')$ is an isomorphism $\varphi : \mathcal{L} \rightarrow \mathcal{L}'$ of invertible sheaves such that the diagram

$$\begin{array}{ccc} \mathcal{L}^{\otimes n} & \xrightarrow{\alpha} & \mathcal{O}_S \\ \varphi^{\otimes n} \downarrow & & \downarrow 1 \\ (\mathcal{L}')^{\otimes n} & \xrightarrow{\alpha'} & \mathcal{O}_S \end{array}$$

commutes. Thus we have

(44.28.4.1)

$$Isom_S((\mathcal{L}, \alpha), (\mathcal{L}', \alpha')) = \begin{cases} \emptyset & \text{if they are not isomorphic} \\ H^0(S, \mu_{n,S}) \cdot \varphi & \text{if } \varphi \text{ isomorphism of pairs} \end{cases}$$

Moreover, given two pairs $(\mathcal{L}, \alpha), (\mathcal{L}', \alpha')$ the tensor product

$$(\mathcal{L}, \alpha) \otimes (\mathcal{L}', \alpha') = (\mathcal{L} \otimes \mathcal{L}', \alpha \otimes \alpha')$$

is another pair. The pair $(\mathcal{O}_S, 1)$ is an identity for this tensor product operation, and an inverse is given by

$$(\mathcal{L}, \alpha)^{-1} = (\mathcal{L}^{\otimes -1}, \alpha^{\otimes -1}).$$

Hence the collection of isomorphism classes of pairs forms an abelian group. Note that

$$(\mathcal{L}, \alpha)^{\otimes n} = (\mathcal{L}^{\otimes n}, \alpha^{\otimes n}) \xrightarrow{\alpha} (\mathcal{O}_S, 1)$$

hence every element of this group has order dividing n . We warn the reader that this group is in general **not** the n -torsion in $\text{Pic}(S)$.

Lemma 44.28.5. *Let S be a scheme. There is a canonical identification*

$$H_{\acute{e}tale}^1(S, \mu_n) = \text{group of pairs } (\mathcal{L}, \alpha) \text{ up to isomorphism as above}$$

if n is invertible on S . In general we have

$$H_{fppf}^1(S, \mu_n) = \text{group of pairs } (\mathcal{L}, \alpha) \text{ up to isomorphism as above.}$$

The same result holds with fppf replaced by syntomic.

Proof. We first prove the second isomorphism. Let (\mathcal{L}, α) be a pair as above. Choose an affine open covering $S = \bigcup U_i$ such that $\mathcal{L}|_{U_i} \cong \mathcal{O}_{U_i}$. Say $s_i \in \mathcal{L}(U_i)$ is a generator. Then $\alpha(s_i^{\otimes n}) = f_i \in \mathcal{O}_S^*(U_i)$. Writing $U_i = \text{Spec}(A_i)$ we see there exists a global relative complete intersection $A_i \rightarrow B_i = A_i[T]/(T^n - f_i)$ such that f_i maps to an n th power in B_i . In other words, setting $V_i = \text{Spec}(B_i)$ we obtain a syntomic covering $\mathcal{V} = \{V_i \rightarrow S\}_{i \in I}$ and trivializations $\varphi_i : (\mathcal{L}, \alpha)|_{V_i} \rightarrow (\mathcal{O}_{V_i}, 1)$.

We will use this result (the existence of the covering \mathcal{V}) to associate to this pair a cohomology class in $H_{\text{syntomic}}^1(S, \mu_{n,S})$. We give two (equivalent) constructions.

First construction: using Čech cohomology. Over the double overlaps $V_i \times_S V_j$ we have the isomorphism

$$(\mathcal{O}_{V_i \times_S V_j}, 1) \xrightarrow{\text{pr}_0^* \varphi_i^{-1}} (\mathcal{L}|_{V_i \times_S V_j}, \alpha|_{V_i \times_S V_j}) \xrightarrow{\text{pr}_1^* \varphi_j} (\mathcal{O}_{V_i \times_S V_j}, 1)$$

of pairs. By (44.28.4.1) this is given by an element $\zeta_{ij} \in \mu_n(V_i \times_S V_j)$. We omit the verification that these ζ_{ij} 's give a 1-cocycle, i.e., give an element $(\zeta_{i_0 i_1}) \in \check{C}(\mathcal{V}, \mu_n)$ with $d(\zeta_{i_0 i_1}) = 0$. Thus its class is an element in $\check{H}^1(\mathcal{V}, \mu_n)$ and by Theorem 44.19.2 it maps to a cohomology class in $H_{\text{syntomic}}^1(S, \mu_{n,S})$.

Second construction: Using torsors. Consider the presheaf

$$\mu_n(\mathcal{L}, \alpha) : U \mapsto Isom_U((\mathcal{O}_U, 1), (\mathcal{L}, \alpha)|_U)$$

on $(Sch/S)_{\text{syntomic}}$. We may view this as a subsheaf of $\mathcal{H}om_{\mathcal{O}}(\mathcal{O}, \mathcal{L})$ (internal hom sheaf, see Modules on Sites, Section 18.27). Since the conditions defining this subsheaf are local, we see that it is a sheaf. By (44.28.4.1) this sheaf has a free action of the sheaf $\mu_{n,S}$. Hence the only thing we have to check is that it locally has sections. This is true because of the existence of the trivializing cover \mathcal{V} . Hence

$\mu_n(\mathcal{L}, \alpha)$ is a $\mu_{n,S}$ -torsor and by Cohomology on Sites, Lemma 21.5.3 we obtain a corresponding element of $H_{\text{syntomic}}^1(S, \mu_{n,S})$.

Ok, now we have to still show the following

- (1) The two constructions give the same cohomology class.
- (2) Isomorphic pairs give rise to the same cohomology class.
- (3) The cohomology class of $(\mathcal{L}, \alpha) \otimes (\mathcal{L}', \alpha')$ is the sum of the cohomology classes of (\mathcal{L}, α) and (\mathcal{L}', α') .
- (4) If the cohomology class is trivial, then the pair is trivial.
- (5) Any element of $H_{\text{syntomic}}^1(S, \mu_{n,S})$ is the cohomology class of a pair.

We omit the proof of (1). Part (2) is clear from the second construction, since isomorphic torsors give the same cohomology classes. Part (3) is clear from the first construction, since the resulting Čech classes add up. Part (4) is clear from the second construction since a torsor is trivial if and only if it has a global section, see Cohomology on Sites, Lemma 21.5.2.

Part (5) can be seen as follows (although a direct proof would be preferable). Suppose $\xi \in H_{\text{syntomic}}^1(S, \mu_{n,S})$. Then ξ maps to an element $\bar{\xi} \in H_{\text{syntomic}}^1(S, \mathbf{G}_{m,S})$ with $n\bar{\xi} = 0$. By Theorem 44.24.1 we see that $\bar{\xi}$ corresponds to an invertible sheaf \mathcal{L} whose n th tensor power is isomorphic to \mathcal{O}_S . Hence there exists a pair (\mathcal{L}, α') whose cohomology class ξ' has the same image $\bar{\xi}'$ in $H_{\text{syntomic}}^1(S, \mathbf{G}_{m,S})$. Thus it suffices to show that $\xi - \xi'$ is the class of a pair. By construction, and the long exact cohomology sequence above, we see that $\xi - \xi' = \partial(f)$ for some $f \in H^0(S, \mathcal{O}_S^*)$. Consider the pair (\mathcal{O}_S, f) . We omit the verification that the cohomology class of this pair is $\partial(f)$, which finishes the proof of the first identification (with fppf replaced with syntomic).

To see the first, note that if n is invertible on S , then the covering \mathcal{V} constructed in the first part of the proof is actually an étale covering (compare with the proof of Lemma 44.28.1). The rest of the proof is independent of the topology, apart from the very last argument which uses that the Kummer sequence is exact, i.e., uses Lemma 44.28.1. \square

44.29. Neighborhoods, stalks and points

We can associate to any geometric point of S a stalk functor which is exact. A map of sheaves on $S_{\text{étale}}$ is an isomorphism if and only if it is an isomorphism on all these stalks. A complex of abelian sheaves is exact if and only if the complex of stalks is exact at all geometric points. Altogether this means that the small étale site of a scheme S has enough points. It also turns out that any point of the small étale topos of S (an abstract notion) is given by a geometric point. Thus in some sense the small étale topos of S can be understood in terms of geometric points and neighbourhoods.

Definition 44.29.1. Let S be a scheme.

- (1) A *geometric point* of S is a morphism $\text{Spec}(k) \rightarrow S$ where k is algebraically closed. Such a point is usually denoted \bar{s} , i.e., by an overlined small case letter. We often use \bar{s} to denote the scheme $\text{Spec}(k)$ as well as the morphism, and we use $\kappa(\bar{s})$ to denote k .
- (2) We say \bar{s} *lies over* s to indicate that $s \in S$ is the image of \bar{s} .

- (3) An *étale neighborhood* of a geometric point \bar{s} of S is a commutative diagram

$$\begin{array}{ccc} & & U \\ & \nearrow \bar{u} & \downarrow \varphi \\ \bar{s} & \xrightarrow{\bar{s}} & S \end{array}$$

where φ is an étale morphism of schemes. We write $(U, \bar{u}) \rightarrow (S, \bar{s})$.

- (4) A *morphism of étale neighborhoods* $(U, \bar{u}) \rightarrow (U', \bar{u}')$ is an S -morphism $h : U \rightarrow U'$ such that $\bar{u}' = h \circ \bar{u}$.

Remark 44.29.2. Since U and U' are étale over S , any S -morphism between them is also étale, see Proposition 44.26.2. In particular all morphisms of étale neighborhoods are étale.

Remark 44.29.3. Let S be a scheme and $s \in S$ a point. In More on Morphisms, Definition 36.27.1 we defined the notion of an étale neighbourhood $(U, u) \rightarrow (S, s)$ of (S, s) . If \bar{s} is a geometric point of S lying over s , then any étale neighbourhood $(U, \bar{u}) \rightarrow (S, \bar{s})$ gives rise to an étale neighbourhood (U, u) of (S, s) by taking $u \in U$ to be the unique point of U such that \bar{u} lies over u . Conversely, given an étale neighbourhood (U, u) of (S, s) the residue field extension $\kappa(s) \subset \kappa(u)$ is finite separable (see Proposition 44.26.2) and hence we can find an embedding $\kappa(u) \subset \kappa(\bar{s})$ over $\kappa(s)$. In other words, we can find a geometric point \bar{u} of U lying over u such that (U, \bar{u}) is an étale neighbourhood of (S, \bar{s}) . We will use these observations to go between the two types of étale neighbourhoods.

Lemma 44.29.4. *Let S be a scheme, and let \bar{s} be a geometric point of S . The category of étale neighborhoods is cofiltered. More precisely:*

- (1) *Let $(U_i, \bar{u}_i)_{i=1,2}$ be two étale neighborhoods of \bar{s} in S . Then there exists a third étale neighborhood (U, \bar{u}) and morphisms $(U, \bar{u}) \rightarrow (U_i, \bar{u}_i)$, $i = 1, 2$.*
- (2) *Let $h_1, h_2 : (U, \bar{u}) \rightarrow (U', \bar{u}')$ be two morphisms between étale neighborhoods of \bar{s} . Then there exist an étale neighborhood (U'', \bar{u}'') and a morphism $h : (U'', \bar{u}'') \rightarrow (U, \bar{u})$ which equalizes h_1 and h_2 , i.e., such that $h_1 \circ h = h_2 \circ h$.*

Proof. For part (1), consider the fibre product $U = U_1 \times_S U_2$. It is étale over both U_1 and U_2 because étale morphisms are preserved under base change, see Proposition 44.26.2. The map $\bar{s} \rightarrow U$ defined by (\bar{u}_1, \bar{u}_2) gives it the structure of an étale neighborhood mapping to both U_1 and U_2 . For part (2), define U'' as the fibre product

$$\begin{array}{ccc} U'' & \longrightarrow & U \\ \downarrow & & \downarrow (h_1, h_2) \\ U' & \xrightarrow{\Delta} & U' \times_S U' \end{array}$$

Since \bar{u} and \bar{u}' agree over S with \bar{s} , we see that $\bar{u}'' = (\bar{u}, \bar{u}')$ is a geometric point of U'' . In particular $U'' \neq \emptyset$. Moreover, since U' is étale over S , so is the fibre product $U' \times_S U'$ (see Proposition 44.26.2). Hence the vertical arrow (h_1, h_2) is étale by Remark 44.29.2 above. Therefore U'' is étale over U' by base change, and hence also étale over S (because compositions of étale morphisms are étale). Thus (U'', \bar{u}'') is a solution to the problem. \square

Lemma 44.29.5. *Let S be a scheme. Let \bar{s} be a geometric point of S . Let (U, \bar{u}) an étale neighborhood of \bar{s} . Let $\mathcal{U} = \{\varphi_i : U_i \rightarrow U\}_{i \in I}$ be an étale covering. Then there exist $i \in I$ and $\bar{u}_i : \bar{s} \rightarrow U_i$ such that $\varphi_i : (U_i, \bar{u}_i) \rightarrow (U, \bar{u})$ is a morphism of étale neighborhoods.*

Proof. As $U = \bigcup_{i \in I} \varphi_i(U_i)$, the fibre product $\bar{s} \times_{\bar{u}, U, \varphi_i} U_i$ is not empty for some i . Then look at the cartesian diagram

$$\begin{array}{ccc} \bar{s} \times_{\bar{u}, U, \varphi_i} U_i & \xrightarrow{\text{pr}_2} & U_i \\ \sigma \uparrow & \downarrow \text{pr}_1 & \downarrow \varphi_i \\ \text{Spec}(k) = \bar{s} & \xrightarrow{\bar{u}} & U \end{array}$$

The projection pr_1 is the base change of an étale morphisms so it is étale, see Proposition 44.26.2. Therefore, $\bar{s} \times_{\bar{u}, U, \varphi_i} U_i$ is a disjoint union of finite separable extensions of k , by Proposition 44.26.2. Here $\bar{s} = \text{Spec}(k)$. But k is algebraically closed, so all these extensions are trivial, and there exists a section σ of pr_1 . The composition $\text{pr}_2 \circ \sigma$ gives a map compatible with \bar{u} . \square

Definition 44.29.6. Let S be a scheme. Let \mathcal{F} be a presheaf on $S_{\text{étale}}$. Let \bar{s} be a geometric point of S . The *stalk* of \mathcal{F} at \bar{s} is

$$\mathcal{F}_{\bar{s}} = \text{colim}_{(U, \bar{u})} \mathcal{F}(U)$$

where (U, \bar{u}) runs over all étale neighborhoods of \bar{s} in S .

By Lemma 44.29.4, this colimit is over a filtered index category, namely the opposite of the category of étale neighbourhoods. In other words, an element of $\mathcal{F}_{\bar{s}}$ can be thought of as a triple (U, \bar{u}, σ) where $\sigma \in \mathcal{F}(U)$. Two triples (U, \bar{u}, σ) , (U', \bar{u}', σ') define the same element of the stalk if there exists a third étale neighbourhood (U'', \bar{u}'') and morphisms of étale neighbourhoods $h : (U'', \bar{u}'') \rightarrow (U, \bar{u})$, $h' : (U'', \bar{u}'') \rightarrow (U', \bar{u}')$ such that $h^* \sigma = (h')^* \sigma'$ in $\mathcal{F}(U'')$. See Categories, Section 4.19.

Lemma 44.29.7. *Let S be a scheme. Let \bar{s} be a geometric point of S . Consider the functor*

$$\begin{aligned} u : S_{\text{étale}} &\longrightarrow \text{Sets}, \\ U &\longmapsto |U_{\bar{s}}| = \{\bar{u} \text{ such that } (U, \bar{u}) \text{ is an étale neighbourhood of } \bar{s}\}. \end{aligned}$$

Here $|U_{\bar{s}}|$ denotes the underlying set of the geometric fibre. Then u defines a point p of the site $S_{\text{étale}}$ (Sites, Definition 7.31.2) and its associated stalk functor $\mathcal{F} \mapsto \mathcal{F}_p$ (Sites, Equation 7.31.1.1) is the functor $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ defined above.

Proof. In the proof of Lemma 44.29.5 we have seen that the scheme $U_{\bar{s}}$ is a disjoint union of schemes isomorphic to \bar{s} . Thus we can also think of $|U_{\bar{s}}|$ as the set of geometric points of U lying over \bar{s} , i.e., as the collection of morphisms $\bar{u} : \bar{s} \rightarrow U$ fitting into the diagram of Definition 44.29.1. From this it follows that $u(S)$ is a singleton, and that $u(U \times_V W) = u(U) \times_{u(V)} u(W)$ whenever $U \rightarrow V$ and $W \rightarrow V$ are morphisms in $S_{\text{étale}}$. And, given a covering $\{U_i \rightarrow U\}_{i \in I}$ in $S_{\text{étale}}$ we see that $\coprod u(U_i) \rightarrow u(U)$ is surjective by Lemma 44.29.5. Hence Sites, Proposition 7.32.2 applies, so p is a point of the site $S_{\text{étale}}$. Finally, the our functor $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ is given by exactly the same colimit as the functor $\mathcal{F} \mapsto \mathcal{F}_p$ associated to p in Sites, Equation 7.31.1.1 which proves the final assertion. \square

Remark 44.29.8. Let S be a scheme and let $\bar{s} : \text{Spec}(k) \rightarrow S$ and $\bar{s}' : \text{Spec}(k') \rightarrow S$ be two geometric points of S . A *morphism $a : \bar{s} \rightarrow \bar{s}'$ of geometric points* is simply a morphism $a : \text{Spec}(k) \rightarrow \text{Spec}(k')$ such that $a \circ \bar{s}' = \bar{s}$. Given such a morphism we obtain a functor from the category of étale neighbourhoods of \bar{s}' to the category of étale neighbourhoods of \bar{s} by the rule $(U, \bar{u}') \mapsto (U, \bar{u}' \circ a)$. Hence we obtain a canonical map

$$\mathcal{F}_{\bar{s}'} = \text{colim}_{(U, \bar{u}')} \mathcal{F}(U) \longrightarrow \text{colim}_{(U, \bar{u})} \mathcal{F}(U) = \mathcal{F}_{\bar{s}}$$

from Categories, Lemma 4.14.7. Using the description of elements of stalks as triples this maps the element of $\mathcal{F}_{\bar{s}'}$ represented by the triple (U, \bar{u}', σ) to the element of $\mathcal{F}_{\bar{s}}$ represented by the triple $(U, \bar{u}' \circ a, \sigma)$. Since the functor above is clearly an equivalence we conclude that this canonical map is an isomorphism of stalk functors.

Let us make sure we have the map of stalks corresponding to a pointing in the correct direction. Note that the above means, according to Sites, Definition 7.36.2, that a defines a morphism $a : p \rightarrow p'$ between the points p, p' of the site $S_{\text{étale}}$ associated to \bar{s}, \bar{s}' by Lemma 44.29.7. There are more general morphisms of points (corresponding to specializations of points of S) which we will describe later, and which will not be isomorphisms (insert future reference here).

Lemma 44.29.9. *Let S be a scheme. Let \bar{s} be a geometric point of S .*

- (1) *The stalk functor $PAb(S_{\text{étale}}) \rightarrow Ab$, $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ is exact.*
- (2) *We have $(\mathcal{F}^{\#})_{\bar{s}} = \mathcal{F}_{\bar{s}}$ for any presheaf of sets \mathcal{F} on $S_{\text{étale}}$.*
- (3) *The functor $Ab(S_{\text{étale}}) \rightarrow Ab$, $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ is exact.*
- (4) *Similarly the functors $PSh(S_{\text{étale}}) \rightarrow \text{Sets}$ and $Sh(S_{\text{étale}}) \rightarrow \text{Sets}$ given by the stalk functor $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ are exact (see Categories, Definition 4.23.1) and commute with arbitrary colimits.*

Proof. Before we indicate how to prove this by direct arguments we note that the result follows from the general material in Modules on Sites, Section 18.35. This is true because $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ comes from a point of the small étale site of S , see Lemma 44.29.7. We will only give a direct proof of (1), (2) and (3), and omit a direct proof of (4).

Exactness as a functor on $PAb(S_{\text{étale}})$ is formal from the fact that directed colimits commute with all colimits and with finite limits. The identification of the stalks in (2) is via the map

$$\kappa : \mathcal{F}_{\bar{s}} \longrightarrow (\mathcal{F}^{\#})_{\bar{s}}$$

induced by the natural morphism $\mathcal{F} \rightarrow \mathcal{F}^{\#}$, see Theorem 44.13.2. We claim that this map is an isomorphism of abelian groups. We will show injectivity and omit the proof of surjectivity.

Let $\sigma \in \mathcal{F}_{\bar{s}}$. There exists an étale neighborhood $(U, \bar{u}) \rightarrow (S, \bar{s})$ such that σ is the image of some section $s \in \mathcal{F}(U)$. If $\kappa(\sigma) = 0$ in $(\mathcal{F}^{\#})_{\bar{s}}$ then there exists a morphism of étale neighborhoods $(U', \bar{u}') \rightarrow (U, \bar{u})$ such that $s|_{U'}$ is zero in $\mathcal{F}^{\#}(U')$. It follows there exists an étale covering $\{U'_i \rightarrow U'\}_{i \in I}$ such that $s|_{U'_i} = 0$ in $\mathcal{F}(U'_i)$ for all i . By Lemma 44.29.5 there exist $i \in I$ and a morphism $\bar{u}'_i : \bar{s} \rightarrow U'_i$ such that $(U'_i, \bar{u}'_i) \rightarrow (U', \bar{u}') \rightarrow (U, \bar{u})$ are morphisms of étale neighborhoods. Hence $\sigma = 0$ since $(U'_i, \bar{u}'_i) \rightarrow (U, \bar{u})$ is a morphism of étale neighbourhoods such that we have $s|_{U'_i} = 0$. This proves κ is injective.

To show that the functor $Ab(S_{\acute{e}tale}) \rightarrow Ab$ is exact, consider any short exact sequence in $Ab(S_{\acute{e}tale})$: $0 \rightarrow \mathcal{F} \rightarrow \mathcal{G} \rightarrow \mathcal{H} \rightarrow 0$. This gives us the exact sequence of presheaves

$$0 \rightarrow \mathcal{F} \rightarrow \mathcal{G} \rightarrow \mathcal{H} \rightarrow \mathcal{H}/^p\mathcal{G} \rightarrow 0,$$

where $/^p$ denotes the quotient in $PAb(S_{\acute{e}tale})$. Taking stalks at \bar{s} , we see that $(\mathcal{H}/^p\mathcal{G})_{\bar{s}} = (\mathcal{H}/\mathcal{G})_{\bar{s}} = 0$, since the sheafification of $\mathcal{H}/^p\mathcal{G}$ is 0. Therefore,

$$0 \rightarrow \mathcal{F}_{\bar{s}} \rightarrow \mathcal{G}_{\bar{s}} \rightarrow \mathcal{H}_{\bar{s}} \rightarrow 0 = (\mathcal{H}/^p\mathcal{G})_{\bar{s}}$$

is exact, since taking stalks is exact as a functor from presheaves. \square

Theorem 44.29.10. *Let S be a scheme. A map $a : \mathcal{F} \rightarrow \mathcal{G}$ of sheaves of sets is injective (resp. surjective) if and only if the map on stalks $a_{\bar{s}} : \mathcal{F}_{\bar{s}} \rightarrow \mathcal{G}_{\bar{s}}$ is injective (resp. surjective) for all geometric points of S . A sequence of abelian sheaves on $S_{\acute{e}tale}$ is exact if and only if it is exact on all stalks at geometric points of S .*

Proof. The necessity of exactness on stalks follows from Lemma 44.29.9. For the converse, it suffices to show that a map of sheaves is surjective (respectively injective) if and only if it is surjective (respectively injective) on all stalks. We prove this in the case of surjectivity, and omit the proof in the case of injectivity.

Let $\alpha : \mathcal{F} \rightarrow \mathcal{G}$ be a map of abelian sheaves such that $\mathcal{F}_{\bar{s}} \rightarrow \mathcal{G}_{\bar{s}}$ is surjective for all geometric points. Fix $U \in \text{Ob}(S_{\acute{e}tale})$ and $s \in \mathcal{G}(U)$. For every $u \in U$ choose some $\bar{u} \rightarrow U$ lying over u and an étale neighborhood $(V_u, \bar{v}_u) \rightarrow (U, \bar{u})$ such that $s|_{V_u} = \alpha(s_{V_u})$ for some $s_{V_u} \in \mathcal{F}(V_u)$. This is possible since α is surjective on stalks. Then $\{V_u \rightarrow U\}_{u \in U}$ is an étale covering on which the restrictions of s are in the image of the map α . Thus, α is surjective, see Sites, Section 7.12. \square

Remarks 44.29.11. On points of the geometric sites.

- (1) Theorem 44.29.10 says that the family of points of $S_{\acute{e}tale}$ given by the geometric points of S (Lemma 44.29.7) is conservative, see Sites, Definition 7.37.1. In particular $S_{\acute{e}tale}$ has enough points.
- (2) Suppose \mathcal{F} is a sheaf on the big étale site of S . Let $T \rightarrow S$ be an object of the big étale site of S , and let \bar{t} be a geometric point of T . Then we define $\mathcal{F}_{\bar{t}}$ as the stalk of the restriction $\mathcal{F}|_{T_{\acute{e}tale}}$ of \mathcal{F} to the small étale site of T . In other words, we can define the stalk of \mathcal{F} at any geometric point of any scheme $T/S \in \text{Ob}((Sch/S)_{\acute{e}tale})$.
- (3) The big étale site of S also has enough points, by considering all geometric points of all objects of this site, see (2).

The following lemma should be skipped on a first reading.

Lemma 44.29.12. *Let S be a scheme.*

- (1) *Let p be a point of the small étale site $S_{\acute{e}tale}$ of S given by a functor $u : S_{\acute{e}tale} \rightarrow \text{Sets}$. Then there exists a geometric point \bar{s} of S such that p is isomorphic to the point of $S_{\acute{e}tale}$ associated to \bar{s} in Lemma 44.29.7.*
- (2) *Let $p : Sh(pt) \rightarrow Sh(S_{\acute{e}tale})$ be a point of the small étale topos of S . Then p comes from a geometric point of S , i.e., the stalk functor $\mathcal{F} \mapsto \mathcal{F}_p$ is isomorphic to a stalk functor as defined in Definition 44.29.6.*

Proof. By Sites, Lemma 7.31.7 there is a one to one correspondence between points of the site and points of the associated topos, hence it suffices to prove (1). By Sites, Proposition 7.32.2 the functor u has the following properties: (a) $u(S) = \{*\}$,

(b) $u(U \times_V W) = u(U) \times_{u(V)} u(W)$, and (c) if $\{U_i \rightarrow U\}$ is an étale covering, then $\coprod u(U_i) \rightarrow u(U)$ is surjective. In particular, if $U' \subset U$ is an open subscheme, then $u(U') \subset u(U)$. Moreover, by Sites, Lemma 7.31.7 we can write $u(U) = p^{-1}(h_U^\#)$, in other words $u(U)$ is the stalk of the representable sheaf h_U . If $U = V \amalg W$, then we see that $h_U = (h_V \amalg h_W)^\#$ and we get $u(U) = u(V) \amalg u(W)$ since p^{-1} is exact.

Consider the restriction of u to S_{Zar} . By Sites, Examples 7.32.4 and 7.32.5 there exists a unique point $s \in S$ such that for $S' \subset S$ open we have $u(S') = \{*\}$ if $s \in S'$ and $u(S') = \emptyset$ if $s \notin S'$. Note that if $\varphi : U \rightarrow S$ is an object of $S_{\acute{e}tale}$ then $\varphi(U) \subset S$ is open (see Proposition 44.26.2) and $\{U \rightarrow \varphi(U)\}$ is an étale covering. Hence we conclude that $u(U) = \emptyset \Leftrightarrow s \in \varphi(U)$.

Pick a geometric point $\bar{s} : \bar{s} \rightarrow S$ lying over s , see Definition 44.29.1 for customary abuse of notation. Suppose that $\varphi : U \rightarrow S$ is an object of $S_{\acute{e}tale}$ with U affine. Note that φ is separated, and that the fibre U_s of φ over s is an affine scheme over $\text{Spec}(\kappa(s))$ which is the spectrum of a finite product of finite separable extensions k_i of $\kappa(s)$. Hence we may apply Étale Morphisms, Lemma 40.18.2 to get an étale neighbourhood (V, \bar{v}) of (S, \bar{s}) such that

$$U \times_S V = U_1 \amalg \dots \amalg U_n \amalg W$$

with $U_i \rightarrow V$ an isomorphism and W having no point lying over \bar{v} . Thus we conclude that

$$u(U) \times u(V) = u(U \times_S V) = u(U_1) \amalg \dots \amalg u(U_n) \amalg u(W)$$

and of course also $u(U_i) = u(V)$. After shrinking V a bit we can assume that V has exactly one point lying over s , and hence W has no point lying over s . By the above this then gives $u(W) = \emptyset$. Hence we obtain

$$u(U) \times u(V) = u(U_1) \amalg \dots \amalg u(U_n) = \coprod_{i=1, \dots, n} u(V)$$

Note that $u(V) \neq \emptyset$ as s is in the image of $V \rightarrow S$. In particular, we see that in this situation $u(U)$ is a finite set with n elements.

Consider the limit

$$\lim_{(V, \bar{v})} u(V)$$

over the category of étale neighbourhoods (V, \bar{v}) of \bar{s} . It is clear that we get the same value when taking the limit over the subcategory of (V, \bar{v}) with V affine. By the previous paragraph (applied with the roles of V and U switched) we see that in this case $u(V)$ is always a finite nonempty set. Moreover, the limit is cofiltered, see Lemma 44.29.4. Hence by Categories, Section 4.20 the limit is nonempty. Pick an element x from this limit. This means we obtain a $x_{V, \bar{v}} \in u(V)$ for every étale neighbourhood (V, \bar{v}) of (S, \bar{s}) such that for every morphism of étale neighbourhoods $\varphi : (V', \bar{v}') \rightarrow (V, \bar{v})$ we have $u(\varphi)(x_{V', \bar{v}'}) = x_{V, \bar{v}}$.

We will use the choice of x to construct a functorial bijective map

$$c : |U_{\bar{s}}| \longrightarrow u(U)$$

for $U \in \text{Ob}(S_{\acute{e}tale})$ which will conclude the proof. See Lemma 44.29.7 and its proof for a description of $|U_{\bar{s}}|$. First we claim that it suffices to construct the map for U affine. We omit the proof of this claim. Assume $U \rightarrow S$ in $S_{\acute{e}tale}$ with U affine, and let $\bar{u} : \bar{s} \rightarrow U$ be an element of $|U_{\bar{s}}|$. Choose a (V, \bar{v}) such that $U \times_S V$ decomposes as in the third paragraph of the proof. Then the pair (\bar{u}, \bar{v}) gives a geometric

point of $U \times_S V$ lying over \bar{v} and determines one of the components U_i of $U \times_S V$. More precisely, there exists a section $\sigma : V \rightarrow U \times_S V$ of the projection pr_U such that $(\bar{u}, \bar{v}) = \sigma \circ \bar{v}$. Set $c(\bar{u}) = u(\text{pr}_U)(u(\sigma)(x_{V, \bar{v}})) \in u(U)$. We have to check this is independent of the choice of (V, \bar{v}) . By Lemma 44.29.4 the category of étale neighbourhoods is cofiltered. Hence it suffice to show that given a morphism of étale neighbourhood $\varphi : (V', \bar{v}') \rightarrow (V, \bar{v})$ and a choice of a section $\sigma' : V' \rightarrow U \times_S V'$ of the projection such that $(\bar{u}, \bar{v}') = \sigma' \circ \bar{v}'$ we have $u(\sigma')(x_{V', \bar{v}'}) = u(\sigma)(x_{V, \bar{v}})$. Consider the diagram

$$\begin{array}{ccc} V' & \xrightarrow{\quad \varphi \quad} & V \\ \downarrow \sigma' & & \downarrow \sigma \\ U \times_S V' & \xrightarrow{1 \times \varphi} & U \times_S V \end{array}$$

Now, it may not be the case that this diagram commutes. The reason is that the schemes V' and V may not be connected, and hence the decompositions used to construct σ' and σ above may not be unique. But we do know that $\sigma \circ \varphi \circ \bar{v}' = (1 \times \varphi) \circ \sigma' \circ \bar{v}'$ by construction. Hence, since $U \times_S V$ is étale over S , there exists an open neighbourhood $V'' \subset V'$ of \bar{v}' such that the diagram does commute when restricted to V'' , see Morphisms, Lemma 28.36.17. This means we may extend the diagram above to

$$\begin{array}{ccccc} V'' & \longrightarrow & V' & \xrightarrow{\quad \varphi \quad} & V \\ \downarrow \sigma'|_{V''} & & \downarrow \sigma' & & \downarrow \sigma \\ U \times_S V'' & \longrightarrow & U \times_S V' & \xrightarrow{1 \times \varphi} & U \times_S V \end{array}$$

such that the left square and the outer rectangle commute. Since u is a functor this implies that $x_{V'', \bar{v}'}$ maps to the same element in $u(U \times_S V)$ no matter which route we take through the diagram. On the other hand, it maps to the elements $x_{V', \bar{v}'}$ and $x_{V, \bar{v}}$ in $u(V')$ and $u(V)$. This implies the desired equality $u(\sigma')(x_{V', \bar{v}'}) = u(\sigma)(x_{V, \bar{v}})$.

In a similar manner one proves that the construction $c : |U_{\bar{s}}| \rightarrow u(U)$ is functorial in U ; details omitted. And finally, by the results of the third paragraph it is clear that the map c is bijective which ends the proof of the lemma. \square

44.30. Points in other topologies

In this section we briefly discuss the existence of points for some sites other than the étale site of a scheme. We refer to Sites, Section 7.37 and Topologies, Section 33.2 ff for the terminology used in this section. All of the geometric sites have enough points.

Lemma 44.30.1. *Let S be a scheme. All of the following sites have enough points S_{Zar} , $S_{\text{étale}}$, $(\text{Sch}/S)_{\text{Zar}}$, $(\text{Aff}/S)_{\text{Zar}}$, $(\text{Sch}/S)_{\text{étale}}$, $(\text{Aff}/S)_{\text{étale}}$, $(\text{Sch}/S)_{\text{smooth}}$, $(\text{Aff}/S)_{\text{smooth}}$, $(\text{Sch}/S)_{\text{syntomic}}$, $(\text{Aff}/S)_{\text{syntomic}}$, $(\text{Sch}/S)_{\text{fppf}}$, and $(\text{Aff}/S)_{\text{fppf}}$.*

Proof. For each of the big sites the associated topos is equivalent to the topos defined by the site $(\text{Aff}/S)_{\tau}$, see Topologies, Lemmas 33.3.10, 33.4.11, 33.5.9, 33.6.9, and 33.7.11. The result for the sites $(\text{Aff}/S)_{\tau}$ follows immediately from Deligne’s result Sites, Proposition 7.38.3.

The result for S_{Zar} is clear. The result for $S_{\acute{e}tale}$ either follows from (the proof of) Theorem 44.29.10 or from Lemma 44.21.2 and Deligne's result applied to $S_{affine,\acute{e}tale}$. \square

The lemma above guarantees the existence of points, but it doesn't tell us what these points look like. We can explicitly construct *some* points as follows. Suppose $\bar{s} : \text{Spec}(k) \rightarrow S$ is a geometric point with k algebraically closed. Consider the functor

$$u : (Sch/S)_{fppf} \longrightarrow Sets, \quad u(U) = U(k) = \text{Mor}_S(\text{Spec}(k), U).$$

Note that $U \mapsto U(k)$ commutes with direct limits as $S(k) = \{\bar{s}\}$ and $(U_1 \times_U U_2)(k) = U_1(k) \times_{U(k)} U_2(k)$. Moreover, if $\{U_i \rightarrow U\}$ is an fppf covering, then $\coprod U_i(k) \rightarrow U(k)$ is surjective. By Sites, Proposition 7.32.2 we see that u defines a point p of $(Sch/S)_{fppf}$ with stalks

$$\mathcal{F}_p = \text{colim}_{(U,x)} \mathcal{F}(U)$$

where the colimit is over pairs $U \rightarrow S$, $x \in U(k)$ as usual. But... this category has an initial object, namely $(\text{Spec}(k), \text{id})$, hence we see that

$$\mathcal{F}_p = \mathcal{F}(\text{Spec}(k))$$

which isn't terribly interesting! In fact, in general these points won't form a conservative family of points. A more interesting type of point is described in the following remark.

Remark 44.30.2. Let $S = \text{Spec}(A)$ be an affine scheme. Let (p, u) be a point of the site $(Aff/S)_{fppf}$, see Sites, Sections 7.31 and 7.32. Let $B = \mathcal{O}_p$ be the stalk of the structure sheaf at the point p . Recall that

$$B = \text{colim}_{(U,x)} \mathcal{O}(U) = \text{colim}_{(\text{Spec}(C), x_C)} C$$

where $x_C \in u(\text{Spec}(C))$. It can happen that $\text{Spec}(B)$ is an object of $(Aff/S)_{fppf}$ and that there is an element $x_B \in u(\text{Spec}(B))$ mapping to the compatible system x_C . In this case the system of neighbourhoods has an initial object and it follows that $\mathcal{F}_p = \mathcal{F}(\text{Spec}(B))$ for any sheaf \mathcal{F} on $(Aff/S)_{fppf}$. It is straightforward to see that if $\mathcal{F} \mapsto \mathcal{F}(\text{Spec}(B))$ defines a point of $Sh((Aff/S)_{fppf})$, then B has to be a local A -algebra such that for every faithfully flat, finitely presented ring map $B \rightarrow B'$ there is a section $B' \rightarrow B$. Conversely, for any such A -algebra B the functor $\mathcal{F} \mapsto \mathcal{F}(\text{Spec}(B))$ is the stalk functor of a point. Details omitted. It is not clear what a general point of the site $(Aff/S)_{fppf}$ looks like.

44.31. Supports of abelian sheaves

First we talk about supports of local sections.

Lemma 44.31.1. *Let S be a scheme. Let \mathcal{F} be a subsheaf of the final object of the étale topos of S (see Sites, Example 7.10.2). Then there exists a unique open $W \subset S$ such that $\mathcal{F} = h_W$.*

Proof. The condition means that $\mathcal{F}(U)$ is a singleton or empty for all $\varphi : U \rightarrow S$ in $\text{Ob}(S_{\acute{e}tale})$. In particular local sections always glue. If $\mathcal{F}(U) \neq \emptyset$, then $\mathcal{F}(\varphi(U)) \neq \emptyset$ because $\{\varphi : U \rightarrow \varphi(U)\}$ is a covering. Hence we can take $W = \bigcup_{\varphi : U \rightarrow S, \mathcal{F}(U) \neq \emptyset} \varphi(U)$. \square

Lemma 44.31.2. *Let S be a scheme. Let \mathcal{F} be an abelian sheaf on $S_{\text{étale}}$. Let $\sigma \in \mathcal{F}(U)$ be a local section. There exists an open subset $W \subset U$ such that*

- (1) $W \subset U$ is the largest Zariski open subset of U such that $\sigma|_W = 0$,
- (2) for every $\varphi : V \rightarrow U$ in $S_{\text{étale}}$ we have

$$\sigma|_V = 0 \Leftrightarrow \varphi(V) \subset W,$$

- (3) for every geometric point \bar{u} of U we have

$$(U, \bar{u}, \sigma) = 0 \text{ in } \mathcal{F}_{\bar{s}} \Leftrightarrow \bar{u} \in W$$

where $\bar{s} = (U \rightarrow S) \circ \bar{u}$.

Proof. Since \mathcal{F} is a sheaf in the étale topology the restriction of \mathcal{F} to U_{Zar} is a sheaf on U in the Zariski topology. Hence there exists a Zariski open W having property (1), see Modules, Lemma 17.5.2. Let $\varphi : V \rightarrow U$ be an arrow of $S_{\text{étale}}$. Note that $\varphi(V) \subset U$ is an open subset and that $\{V \rightarrow \varphi(V)\}$ is an étale covering. Hence if $\sigma|_V = 0$, then by the sheaf condition for \mathcal{F} we see that $\sigma|_{\varphi(V)} = 0$. This proves (2). To prove (3) we have to show that if (U, \bar{u}, σ) defines the zero element of $\mathcal{F}_{\bar{s}}$, then $\bar{u} \in W$. This is true because the assumption means there exists a morphism of étale neighbourhoods $(V, \bar{v}) \rightarrow (U, \bar{u})$ such that $\sigma|_V = 0$. Hence by (2) we see that $V \rightarrow U$ maps into W , and hence $\bar{u} \in W$. \square

Let S be a scheme. Let $s \in S$. Let \mathcal{F} be a sheaf on $S_{\text{étale}}$. By Remark 44.29.8 the isomorphism class of the stalk of the sheaf \mathcal{F} at a geometric points lying over s is well defined.

Definition 44.31.3. Let S be a scheme. Let \mathcal{F} be an abelian sheaf on $S_{\text{étale}}$.

- (1) The *support* of \mathcal{F} is the set of points $s \in S$ such that $\mathcal{F}_{\bar{s}} \neq 0$ for any (some) geometric point \bar{s} lying over s .
- (2) Let $\sigma \in \mathcal{F}(U)$ be a section. The *support* of σ is the closed subset $U \setminus W$, where $W \subset U$ is the largest open subset of U on which σ restricts to zero (see Lemma 44.31.2).

In general the support of an abelian sheaf is not closed. For example, suppose that $S = \text{Spec}(\mathbf{A}_{\mathbf{C}}^1)$. Let $i_t : \text{Spec}(\mathbf{C}) \rightarrow S$ be the inclusion of the point $t \in \mathbf{C}$. We will see later that $\mathbf{F}_t = i_{t,*}(\mathbf{Z}/2\mathbf{Z})$ is an abelian sheaf whose support is exactly $\{t\}$, see Section 44.47. Then

$$\bigoplus_{n \in \mathbf{N}} \mathcal{F}_n$$

is an abelian sheaf with support $\{1, 2, 3, \dots\} \subset S$. This is true because taking stalks commutes with colimits, see Lemma 44.29.9. Thus an example of an abelian sheaf whose support is not closed. Here are some basic facts on supports of sheaves and sections.

Lemma 44.31.4. *Let S be a scheme. Let \mathcal{F} be an abelian sheaf on $S_{\text{étale}}$. Let $U \in \text{Ob}(S_{\text{étale}})$ and $\sigma \in \mathcal{F}(U)$.*

- (1) *The support of σ is closed in U .*
- (2) *The support of $\sigma + \sigma'$ is contained in the union of the supports of $\sigma, \sigma' \in \mathcal{F}(U)$.*
- (3) *If $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ is a map of abelian sheaves on $S_{\text{étale}}$, then the support of $\varphi(\sigma)$ is contained in the support of $\sigma \in \mathcal{F}(U)$.*
- (4) *The support of \mathcal{F} is the union of the images of the supports of all local sections of \mathcal{F} .*

- (5) If $\mathcal{F} \rightarrow \mathcal{G}$ is surjective then the support of \mathcal{G} is a subset of the support of \mathcal{F} .
- (6) If $\mathcal{F} \rightarrow \mathcal{G}$ is injective then the support of \mathcal{F} is a subset of the support of \mathcal{G} .

Proof. Part (1) holds by definition. Parts (2) and (3) hold because they hold for the restriction of \mathcal{F} and \mathcal{G} to U_{Zar} , see Modules, Lemma 17.5.2. Part (4) is a direct consequence of Lemma 44.31.2 part (3). Parts (5) and (6) follow from the other parts. \square

Lemma 44.31.5. *The support of a sheaf of rings on $S_{\acute{e}tale}$ is closed.*

Proof. This is true because (according to our conventions) a ring is 0 if and only if $1 = 0$, and hence the support of a sheaf of rings is the support of the unit section. \square

44.32. Henselian rings

We begin by stating a theorem which has already been used many times in the stacks project. There are many versions of this result; here we just state the algebraic version.

Theorem 44.32.1. *Let $A \rightarrow B$ be finite type ring map and $\mathfrak{p} \subset A$ a prime ideal. Then there exist an étale ring map $A \rightarrow A'$ and a prime $\mathfrak{p}' \subset A'$ lying over \mathfrak{p} such that*

- (1) $\kappa(\mathfrak{p}) = \kappa(\mathfrak{p}')$,
- (2) $B \otimes_A A' = B_1 \times \dots \times B_r \times C$,
- (3) $A' \rightarrow B_i$ is finite and there exists a unique prime $q_i \subset B_i$ lying over \mathfrak{p}' , and
- (4) all irreducible components of the fibre $\text{Spec}(C \otimes_{A'} \kappa(\mathfrak{p}'))$ of C over \mathfrak{p}' have dimension at least 1.

Proof. See Algebra, Lemma 10.138.23, or see [GD67, Théorème 18.12.1]. For a slew of versions in terms of morphisms of schemes, see More on Morphisms, Section 36.30. \square

Recall Hensel's lemma. There are many versions of this lemma. Here are two:

- (f) if $f \in \mathbf{Z}_p[T]$ monic and $f \bmod p = g_0 h_0$ with $\gcd(g_0, h_0) = 1$ then f factors as $f = gh$ with $\bar{g} = g_0$ and $\bar{h} = h_0$,
- (r) if $f \in \mathbf{Z}_p[T]$, monic $a_0 \in \mathbf{F}_p$, $\bar{f}(a_0) = 0$ but $\bar{f}'(a_0) \neq 0$ then there exists $a \in \mathbf{Z}_p$ with $f(a) = 0$ and $\bar{a} = a_0$.

Both versions are true (we will see this later). The first version asks for lifts of factorizations into coprime parts, and the second version asks for lifts of simple roots modulo the maximal ideal. It turns out that requiring these conditions for a general local ring are equivalent, and are equivalent to many other conditions. We use the root lifting property as the definition of a henselian local ring as it is often the easiest one to check.

Definition 44.32.2. (See Algebra, Definition 10.145.1.) A local ring $(R, \mathfrak{m}, \kappa)$ is called *henselian* if for all $f \in R[T]$ monic, for all $a_0 \in \kappa$ such that $\bar{f}(a_0) = 0$ and $\bar{f}'(a_0) \neq 0$, there exists an $a \in R$ such that $f(a) = 0$ and $a \bmod \mathfrak{m} = a_0$.

A good example of henselian local rings to keep in mind is complete local rings. Recall (Algebra, Definition 10.149.1) that a complete local ring is a local ring (R, \mathfrak{m}) such that $R \cong \varprojlim_n R/\mathfrak{m}^n$, i.e., it is complete and separated for the \mathfrak{m} -adic topology.

Theorem 44.32.3. *Complete local rings are henselian.*

Proof. Newton's method. See Algebra, Lemma 10.145.10. \square

Theorem 44.32.4. *Let $(R, \mathfrak{m}, \kappa)$ be a local ring. The following are equivalent:*

- (1) R is henselian,
- (2) for any $f \in R[T]$ and any factorization $\bar{f} = g_0 h_0$ in $\kappa[T]$ with $\gcd(g_0, h_0) = 1$, there exists a factorization $f = gh$ in $R[T]$ with $\bar{g} = g_0$ and $\bar{h} = h_0$,
- (3) any finite R -algebra S is isomorphic to a finite product of finite local rings,
- (4) any finite type R -algebra A is isomorphic to a product $A \cong A' \times C$ where $A' \cong A_1 \times \dots \times A_r$ is a product of finite local R -algebras and all the irreducible components of $C \otimes_R \kappa$ have dimension at least 1,
- (5) if A is an étale R -algebra and \mathfrak{n} is a maximal ideal of A lying over \mathfrak{m} such that $\kappa \cong A/\mathfrak{n}$, then there exists an isomorphism $\varphi : A \cong R \times A'$ such that $\varphi(\mathfrak{n}) = \mathfrak{m} \times A' \subset R \times A'$.

Proof. This is just a subset of the results from Algebra, Lemma 10.145.3. Note that part (5) above corresponds to part (8) of Algebra, Lemma 10.145.3 but is formulated slightly differently. \square

Lemma 44.32.5. *If R is henselian and A is a finite R -algebra, then A is a finite product of henselian local rings.*

Proof. See Algebra, Lemma 10.145.4. \square

Definition 44.32.6. A local ring R is called *strictly henselian* if it is henselian and its residue field is separably closed.

Example 44.32.7. In the case $R = \mathbf{C}[[t]]$, the étale R -algebras are finite products of the trivial extension $R \rightarrow R$ and the extensions $R \rightarrow R[X, X^{-1}]/(X^n - t)$. The latter ones factor through the open $D(t) \subset \text{Spec}(R)$, so any étale covering can be refined by the covering $\{\text{id} : \text{Spec}(R) \rightarrow \text{Spec}(R)\}$. We will see below that this is a somewhat general fact on étale coverings of spectra of henselian rings. This will show that higher étale cohomology of the spectrum of a strictly henselian ring is zero.

Theorem 44.32.8. *Let $(R, \mathfrak{m}, \kappa)$ be a local ring and $\kappa \subset \kappa^{\text{sep}}$ a separable algebraic closure. There exist canonical flat local ring maps $R \rightarrow R^h \rightarrow R^{\text{sh}}$ where*

- (1) R^h, R^{sh} are filtered colimits of étale R -algebras,
- (2) R^h is henselian, R^{sh} is strictly henselian,
- (3) $\mathfrak{m}R^h$ (resp. $\mathfrak{m}R^{\text{sh}}$) is the maximal ideal of R^h (resp. R^{sh}), and
- (4) $\kappa = R^h/\mathfrak{m}R^h$, and $\kappa^{\text{sep}} = R^{\text{sh}}/\mathfrak{m}R^{\text{sh}}$ as extensions of κ .

Proof. The structure of R^h and R^{sh} is described in Algebra, Lemmas 10.145.16 and 10.145.17. \square

The rings constructed in Theorem 44.32.8 are called respectively the *henselization* and the *strict henselization* of the local ring R , see Algebra, Definition 10.145.18. Many of the properties of R are reflected in its (strict) henselization, see More on Algebra, Section 15.34.

44.33. Stalks of the structure sheaf

In this section we identify the stalk of the structure sheaf at a geometric point with the strict henselization of the local ring at the corresponding “usual” point.

Lemma 44.33.1. *Let S be a scheme. Let \bar{s} be a geometric point of S lying over $s \in S$. Let $\kappa = \kappa(s)$ and let $\kappa \subset \kappa^{sep} \subset \kappa(\bar{s})$ denote the separable algebraic closure of κ in $\kappa(\bar{s})$. Then there is a canonical identification*

$$(\mathcal{O}_{S,s})^{sh} \cong \mathcal{O}_{S,\bar{s}}$$

where the left hand side is the strict henselization of the local ring $\mathcal{O}_{S,s}$ as described in Theorem 44.32.8 and right hand side is the stalk of the structure sheaf \mathcal{O}_S on $S_{\acute{e}tale}$ at the geometric point \bar{s} .

Proof. Let $\text{Spec}(A) \subset S$ be an affine neighbourhood of s . Let $\mathfrak{p} \subset A$ be the prime ideal corresponding to s . With these choices we have canonical isomorphisms $\mathcal{O}_{S,s} = A_{\mathfrak{p}}$ and $\kappa(s) = \kappa(\mathfrak{p})$. Thus we have $\kappa(\mathfrak{p}) \subset \kappa^{sep} \subset \kappa(\bar{s})$. Recall that

$$\mathcal{O}_{S,\bar{s}} = \text{colim}_{(U,\bar{u})} \mathcal{O}(U)$$

where the limit is over the étale neighbourhoods of (S, \bar{s}) . A cofinal system is given by those étale neighbourhoods (U, \bar{u}) such that U is affine and $U \rightarrow S$ factors through $\text{Spec}(A)$. In other words, we see that

$$\mathcal{O}_{S,\bar{s}} = \text{colim}_{(B,\mathfrak{q},\phi)} B$$

where the colimit is over étale A -algebras B endowed with a prime \mathfrak{q} lying over \mathfrak{p} and a $\kappa(\mathfrak{p})$ -algebra map $\phi : \kappa(\mathfrak{q}) \rightarrow \kappa(\bar{s})$. Note that since $\kappa(\mathfrak{q})$ is finite separable over $\kappa(\mathfrak{p})$ the image of ϕ is contained in κ^{sep} . Via these translations the result of the lemma is equivalent to the result of Algebra, Lemma 10.145.27. \square

Definition 44.33.2. Let S be a scheme. Let \bar{s} be a geometric point of S lying over the point $s \in S$.

- (1) The *étale local ring of S at \bar{s}* is the stalk of the structure sheaf \mathcal{O}_S on $S_{\acute{e}tale}$ at \bar{s} . We sometimes call this the *strict henselization of $\mathcal{O}_{S,s}$* relative to the geometric point \bar{s} . Notation used: $\mathcal{O}_{S,\bar{s}} = \mathcal{O}_{S,s}^{sh}$.
- (2) The *henselization of $\mathcal{O}_{S,s}$* is the henselization of the local ring of S at s . See Algebra, Definition 10.145.18, and Theorem 44.32.8. Notation: $\mathcal{O}_{S,s}^h$.
- (3) The *strict henselization of S at \bar{s}* is the scheme $\text{Spec}(\mathcal{O}_{S,s}^{sh})$.
- (4) The *henselization of S at s* is the scheme $\text{Spec}(\mathcal{O}_{S,s}^h)$.

Lemma 44.33.3. *Let S be a scheme. Let $s \in S$. Then we have*

$$\mathcal{O}_{S,s}^h = \text{colim}_{(U,u)} \mathcal{O}(U)$$

where the colimit is over the filtered category of étale neighbourhoods (U, u) of (S, s) such that $\kappa(s) = \kappa(u)$.

Proof. This lemma is a copy of More on Morphisms, Lemma 36.27.5. \square

Remark 44.33.4. Let S be a scheme. Let $s \in S$. If S is locally noetherian then $\mathcal{O}_{S,s}^h$ is also noetherian and it has the same completion:

$$\widehat{\mathcal{O}_{S,s}} \cong \widehat{\mathcal{O}_{S,s}^h}.$$

In particular, $\mathcal{O}_{S,s} \subset \mathcal{O}_{S,s}^h \subset \widehat{\mathcal{O}_{S,s}}$. The henselization of $\mathcal{O}_{S,s}$ is in general much smaller than its completion and inherits many of its properties. For example, if $\mathcal{O}_{S,s}$ is reduced, then so is $\mathcal{O}_{S,s}^h$, but this is not true for the completion in general. Insert future references here.

Lemma 44.33.5. *Let S be a scheme. The small étale site $S_{\text{étale}}$ endowed with its structure sheaf \mathcal{O}_S is a locally ringed site, see Modules on Sites, Definition 18.39.4.*

Proof. This follows because the stalks $\mathcal{O}_{S,s}^{sh} = \mathcal{O}_{S,\bar{s}}$ are local, and because $S_{\text{étale}}$ has enough points, see Lemma 44.33.1, Theorem 44.29.10, and Remarks 44.29.11. See Modules on Sites, Lemmas 18.39.2 and 18.39.3 for the fact that this implies the small étale site is locally ringed. \square

44.34. Functoriality of small étale topoi

So far we haven't yet discussed the functoriality of the étale site, in other words what happens when given a morphism of schemes. A precise formal discussion can be found in Topologies, Section 33.4. In this and the next sections we discuss this material briefly specifically in the setting of small étale sites.

Let $f : X \rightarrow Y$ be a morphism of schemes. We obtain a functor

$$(44.34.0.1) \quad u : Y_{\text{étale}} \longrightarrow X_{\text{étale}}, \quad V/Y \longmapsto X \times_Y V/X.$$

This functor has the following important properties

- (1) $u(\text{final object}) = \text{final object}$,
- (2) u preserves fibre products,
- (3) if $\{V_j \rightarrow V\}$ is a covering in $Y_{\text{étale}}$, then $\{u(V_j) \rightarrow u(V)\}$ is a covering in $X_{\text{étale}}$.

Each of these is easy to check (omitted). As a consequence we obtain what is called a *morphism of sites*

$$f_{\text{small}} : X_{\text{étale}} \longrightarrow Y_{\text{étale}},$$

see Sites, Definition 7.15.1 and Sites, Proposition 7.15.6. It is not necessary to know about the abstract notion in detail in order to work with étale sheaves and étale cohomology. It usually suffices to know that there are functors $f_{\text{small},*}$ (pushforward) and f_{small}^{-1} (pullback) on étale sheaves, and to know some of their simple properties. We will discuss these properties in the next sections, but we will sometimes refer to the more abstract material for proofs since that is often the natural setting to prove them.

44.35. Direct images

Let us define the pushforward of a presheaf.

Definition 44.35.1. Let $f : X \rightarrow Y$ be a morphism of schemes. Let \mathcal{F} a presheaf of sets on $X_{\text{étale}}$. The *direct image*, or *pushforward* of \mathcal{F} (under f) is

$$f_*\mathcal{F} : Y_{\text{étale}}^{\text{opp}} \longrightarrow \text{Sets}, \quad (V/Y) \longmapsto \mathcal{F}(X \times_Y V/X).$$

We sometimes write $f_* = f_{\text{small},*}$ to distinguish from other direct image functors (such as usual Zariski pushforward or $f_{\text{big},*}$).

This is a well-defined étale presheaf since the base change of an étale morphism is again étale. A more categorical way of saying this is that $f_*\mathcal{F}$ is the composition of functors $\mathcal{F} \circ u$ where u is as in Equation (44.34.0.1). This makes it clear that the construction is functorial in the presheaf \mathcal{F} and hence we obtain a functor

$$f_* = f_{small,*} : PSh(X_{\acute{e}tale}) \longrightarrow PSh(Y_{\acute{e}tale})$$

Note that if \mathcal{F} is a presheaf of abelian groups, then $f_*\mathcal{F}$ is also a presheaf of abelian groups and we obtain

$$f_* = f_{small,*} : PAb(X_{\acute{e}tale}) \longrightarrow PAb(Y_{\acute{e}tale})$$

as before (i.e., defined by exactly the same rule).

Remark 44.35.2. We claim that the direct image of a sheaf is a sheaf. Namely, if $\{V_j \rightarrow V\}$ is an étale covering in $Y_{\acute{e}tale}$ then $\{X \times_Y V_j \rightarrow X \times_Y V\}$ is an étale covering in $X_{\acute{e}tale}$. Hence the sheaf condition for \mathcal{F} with respect to $\{X \times_Y V_i \rightarrow X \times_Y V\}$ is equivalent to the sheaf condition for $f_*\mathcal{F}$ with respect to $\{V_i \rightarrow V\}$. Thus if \mathcal{F} is a sheaf, so is $f_*\mathcal{F}$.

Definition 44.35.3. Let $f : X \rightarrow Y$ be a morphism of schemes. Let \mathcal{F} a sheaf of sets on $X_{\acute{e}tale}$. The *direct image*, or *pushforward* of \mathcal{F} (under f) is

$$f_*\mathcal{F} : Y_{\acute{e}tale}^{opp} \longrightarrow Sets, \quad (V/Y) \longmapsto \mathcal{F}(X \times_Y V/X)$$

which is a sheaf by Remark 44.35.2. We sometimes write $f_* = f_{small,*}$ to distinguish from other direct image functors (such as usual Zariski pushforward or $f_{big,*}$).

The exact same discussion as above applies and we obtain functors

$$f_* = f_{small,*} : Sh(X_{\acute{e}tale}) \longrightarrow Sh(Y_{\acute{e}tale})$$

and

$$f_* = f_{small,*} : Ab(X_{\acute{e}tale}) \longrightarrow Ab(Y_{\acute{e}tale})$$

called *direct image* again.

The functor f_* on abelian sheaves is left exact. (See Homology, Section 12.7 for what it means for a functor between abelian categories to be left exact.) Namely, if $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3$ is exact on $X_{\acute{e}tale}$, then for every $U/X \in \text{Ob}(X_{\acute{e}tale})$ the sequence of abelian groups $0 \rightarrow \mathcal{F}_1(U) \rightarrow \mathcal{F}_2(U) \rightarrow \mathcal{F}_3(U)$ is exact. Hence for every $V/Y \in \text{Ob}(Y_{\acute{e}tale})$ the sequence of abelian groups $0 \rightarrow f_*\mathcal{F}_1(V) \rightarrow f_*\mathcal{F}_2(V) \rightarrow f_*\mathcal{F}_3(V)$ is exact, because this is the previous sequence with $U = X \times_Y V$.

Definition 44.35.4. Let $f : X \rightarrow Y$ be a morphism of schemes. The right derived functors $\{R^p f_*\}_{p \geq 1}$ of $f_* : Ab(X_{\acute{e}tale}) \rightarrow Ab(Y_{\acute{e}tale})$ are called *higher direct images*.

The higher direct images and their derived category variants are discussed in more detail in (insert future reference here).

44.36. Inverse image

In this section we briefly discuss pullback of sheaves on the small étale sites. The precise construction of this is in Topologies, Section 33.4.

Definition 44.36.1. Let $f : X \rightarrow Y$ be a morphism of schemes. The *inverse image*, or *pullback*² functors are the functors

$$f^{-1} = f_{small}^{-1} : Sh(Y_{\acute{e}tale}) \longrightarrow Sh(X_{\acute{e}tale})$$

and

$$f^{-1} = f_{small}^{-1} : Ab(Y_{\acute{e}tale}) \longrightarrow Ab(X_{\acute{e}tale})$$

which are left adjoint to $f_* = f_{small,*}$. Thus f^{-1} is thus characterized by the fact that

$$\mathrm{Hom}_{Sh(X_{\acute{e}tale})}(f^{-1}\mathcal{G}, \mathcal{F}) = \mathrm{Hom}_{Sh(Y_{\acute{e}tale})}(\mathcal{G}, f_*\mathcal{F})$$

functorially, for any $\mathcal{F} \in Sh(X_{\acute{e}tale})$ and $\mathcal{G} \in Sh(Y_{\acute{e}tale})$. We similarly have

$$\mathrm{Hom}_{Ab(X_{\acute{e}tale})}(f^{-1}\mathcal{G}, \mathcal{F}) = \mathrm{Hom}_{Ab(Y_{\acute{e}tale})}(\mathcal{G}, f_*\mathcal{F})$$

for $\mathcal{F} \in Ab(X_{\acute{e}tale})$ and $\mathcal{G} \in Ab(Y_{\acute{e}tale})$.

It is not trivial that such an adjoint exists. On the other hand, it exists in a fairly general setting, see Remark 44.36.3 below. The general machinery shows that $f^{-1}\mathcal{G}$ is the sheaf associated to the presheaf

$$(44.36.1.1) \quad U/X \longmapsto \mathrm{colim}_{U \rightarrow X \times_Y V} \mathcal{G}(V/Y)$$

where the colimit is over the category of pairs $(V/Y, \varphi : U/X \rightarrow X \times_Y V/X)$. To see this apply Sites, Proposition 7.15.6 to the functor u of Equation (44.34.0.1) and use the description of $u_s = (u_p)^\#$ in Sites, Sections 7.14 and 7.5. We will occasionally use this formula for the pullback in order to prove some of its basic properties.

Lemma 44.36.2. *Let $f : X \rightarrow Y$ be a morphism of schemes.*

- (1) *The functor $f^{-1} : Ab(Y_{\acute{e}tale}) \rightarrow Ab(X_{\acute{e}tale})$ is exact.*
- (2) *The functor $f^{-1} : Sh(Y_{\acute{e}tale}) \rightarrow Sh(X_{\acute{e}tale})$ is exact, i.e., it commutes with finite limits and colimits, see Categories, Definition 4.23.1.*
- (3) *Let $\bar{x} \rightarrow X$ be a geometric point. Let \mathcal{G} be a sheaf on $Y_{\acute{e}tale}$. Then there is a canonical identification*

$$(f^{-1}\mathcal{G})_{\bar{x}} = \mathcal{G}_{\bar{y}}.$$

where $\bar{y} = f \circ \bar{x}$.

- (4) *For any $V \rightarrow Y$ étale we have $f^{-1}h_V = h_{X \times_Y V}$.*

Proof. The exactness of f^{-1} on sheaves of sets is a consequence of Sites, Proposition 7.15.6 applied to our functor u of Equation (44.34.0.1). In fact the exactness of pullback is part of the definition of a morphism of topoi (or sites if you like). Thus we see (2) holds. It implies part (1) since given an abelian sheaf \mathcal{G} on $Y_{\acute{e}tale}$ the underlying sheaf of sets of $f^{-1}\mathcal{F}$ is the same as f^{-1} of the underlying sheaf of sets of \mathcal{F} , see Sites, Section 7.43. See also Modules on Sites, Lemma 18.30.2. In the literature (1) and (2) are sometimes deduced from (3) via Theorem 44.29.10.

Part (3) is a general fact about stalks of pullbacks, see Sites, Lemma 7.33.1. We will also prove (3) directly as follows. Note that by Lemma 44.29.9 taking stalks commutes with sheafification. Now recall that $f^{-1}\mathcal{G}$ is the sheaf associated to the presheaf

$$U \longrightarrow \mathrm{colim}_{U \rightarrow X \times_Y V} \mathcal{G}(V),$$

²We use the notation f^{-1} for pullbacks of sheaves of sets or sheaves of abelian groups, and we reserve f^* for pullbacks of sheaves of modules via a morphism of ringed sites/topoi.

see Equation (44.36.1.1). Thus we have

$$\begin{aligned} (f^{-1}\mathcal{G})_{\bar{x}} &= \operatorname{colim}_{(U,\bar{u})} f^{-1}\mathcal{G}(U) \\ &= \operatorname{colim}_{(U,\bar{u})} \operatorname{colim}_{a:U \rightarrow X \times_Y V} \mathcal{G}(V) \\ &= \operatorname{colim}_{(V,\bar{v})} \mathcal{G}(V) \\ &= \mathcal{G}_{\bar{y}} \end{aligned}$$

in the third equality the pair (U, \bar{u}) and the map $a : U \rightarrow X \times_Y V$ corresponds to the pair $(V, a \circ \bar{u})$.

Part (4) can be proved in a similar manner by identifying the colimits which define $f^{-1}h_V$. Or you can use Yoneda's lemma (Categories, Lemma 4.3.5) and the functorial equalities

$$\operatorname{Mor}_{Sh(X_{\acute{e}tale})}(f^{-1}h_V, \mathcal{F}) = \operatorname{Mor}_{Sh(Y_{\acute{e}tale})}(h_V, f_*\mathcal{F}) = f_*\mathcal{F}(V) = \mathcal{F}(X \times_Y V)$$

combined with the fact that representable presheaves are sheaves. See also Sites, Lemma 7.14.5 for a completely general result. \square

The pair of functors (f_*, f^{-1}) define a morphism of small étale topoi

$$f_{small} : Sh(X_{\acute{e}tale}) \longrightarrow Sh(Y_{\acute{e}tale})$$

Many generalities on cohomology of sheaves hold for topoi and morphisms of topoi. We will try to point out when results are general and when they are specific to the étale topos.

Remark 44.36.3. More generally, let $\mathcal{C}_1, \mathcal{C}_2$ be sites, and assume they have final objects and fibre products. Let $u : \mathcal{C}_2 \rightarrow \mathcal{C}_1$ be a functor satisfying:

- (1) if $\{V_i \rightarrow V\}$ is a covering of \mathcal{C}_2 , then $\{u(V_i) \rightarrow V\}$ is a covering of \mathcal{C}_1 (we say that u is *continuous*), and
- (2) u commutes with finite limits (i.e., u is left exact, i.e., u preserves fibre products and final objects).

Then one can define $f_* : Sh(\mathcal{C}_1) \rightarrow Sh(\mathcal{C}_2)$ by $f_*\mathcal{F}(V) = \mathcal{F}(u(V))$. Moreover, there exists an exact functor f^{-1} which is left adjoint to f_* , see Sites, Definition 7.15.1 and Proposition 7.15.6. Warning: It is not enough to require simply that u is continuous and commutes with fibre products in order to get a morphism of topoi.

44.37. Functoriality of big topoi

Given a morphism of schemes $f : X \rightarrow Y$ there are a whole host of morphisms of topoi associated to f , see Topologies, Section 33.9 for a list. Perhaps the most used ones are the morphisms of topoi

$$f_{big} = f_{big, \tau} : Sh((Sch/X)_{\tau}) \longrightarrow Sh((Sch/Y)_{\tau})$$

where $\tau \in \{Zariski, \acute{e}tale, smooth, syntomic, fppf\}$. These each correspond to a continuous functor

$$(Sch/Y)_{\tau} \longrightarrow (Sch/X)_{\tau}, \quad V/Y \longmapsto X \times_Y V/X$$

which preserves final objects, fibre products and covering, and hence defines a morphism of sites

$$f_{big} : (Sch/X)_{\tau} \longrightarrow (Sch/Y)_{\tau}.$$

See Topologies, Sections 33.3, 33.4, 33.5, 33.6, and 33.7. In particular, pushforward along f_{big} is given by the rule

$$(f_{big,*}\mathcal{F})(V/Y) = \mathcal{F}(X \times_Y V/X)$$

It turns out that these morphisms of topoi have an inverse image functor f_{big}^{-1} which is very easy to describe. Namely, we have

$$(f_{big}^{-1}\mathcal{G})(U/X) = \mathcal{G}(U/Y)$$

where the structure morphism of U/Y is the composition of the structure morphism $U \rightarrow X$ with f , see Topologies, Lemmas 33.3.15, 33.4.15, 33.5.10, 33.6.10, and 33.7.12.

44.38. Functoriality and sheaves of modules

In this section we are going to reformulate some of the material explained in Descent, Section 34.7 in the setting of étale topologies. Let $f : X \rightarrow Y$ be a morphism of schemes. We have seen above, see Sections 44.34, 44.35, and 44.36 that this induces a morphism f_{small} of small étale sites. In Descent, Remark 34.7.4 we have seen that f also induces a natural map

$$f_{small}^{\sharp} : \mathcal{O}_{Y_{\acute{e}tale}} \longrightarrow f_{small,*}\mathcal{O}_{X_{\acute{e}tale}}$$

of sheaves of rings on $Y_{\acute{e}tale}$ such that $(f_{small}, f_{small}^{\sharp})$ is a morphism of ringed sites. See Modules on Sites, Definition 18.6.1 for the definition of a morphism of ringed sites. Let us just recall here that f_{small}^{\sharp} is defined by the compatible system of maps

$$\mathrm{pr}_V^{\sharp} : \mathcal{O}(V) \longrightarrow \mathcal{O}(X \times_Y V)$$

for V varying over the objects of $Y_{\acute{e}tale}$.

It is clear that this construction is compatible with compositions of morphisms of schemes. More precisely, if $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ are morphisms of schemes, then we have

$$(g_{small}, g_{small}^{\sharp}) \circ (f_{small}, f_{small}^{\sharp}) = ((g \circ f)_{small}, (g \circ f)_{small}^{\sharp})$$

as morphisms of ringed topoi. Moreover, by Modules on Sites, Definition 18.13.1 we see that given a morphism $f : X \rightarrow Y$ of schemes we get well defined pullback and direct image functors

$$\begin{aligned} f_{small}^* &: \mathrm{Mod}(\mathcal{O}_{Y_{\acute{e}tale}}) \longrightarrow \mathrm{Mod}(\mathcal{O}_{X_{\acute{e}tale}}), \\ f_{small,*} &: \mathrm{Mod}(\mathcal{O}_{X_{\acute{e}tale}}) \longrightarrow \mathrm{Mod}(\mathcal{O}_{Y_{\acute{e}tale}}) \end{aligned}$$

which are adjoint in the usual way. If $g : Y \rightarrow Z$ is another morphism of schemes, then we have $(g \circ f)_{small}^* = f_{small}^* \circ g_{small}^*$ and $(g \circ f)_{small,*} = g_{small,*} \circ f_{small,*}$ because of what we said about compositions.

There is quite a bit of difference between the category of all \mathcal{O}_X modules on X and the category between all $\mathcal{O}_{X_{\acute{e}tale}}$ -modules on $X_{\acute{e}tale}$. But the results of Descent, Section 34.7 tell us that there is not much difference between considering quasi-coherent modules on S and quasi-coherent modules on $S_{\acute{e}tale}$. (We have already seen this in Theorem 44.17.4 for example.) In particular, if $f : X \rightarrow Y$ is any morphism of schemes, then the pullback functors f_{small}^* and f^* match for quasi-coherent sheaves, see Descent, Proposition 34.7.14. Moreover, the same is true for

pushforward provided f is quasi-compact and quasi-separated, see Descent, Lemma 34.7.15.

A few words about functoriality of the structure sheaf on big sites. Let $f : X \rightarrow Y$ be a morphism of schemes. Choose any of the topologies $\tau \in \{Zariski, \acute{e}tale, smooth, syntomic, fppf\}$. Then the morphism $f_{big} : (Sch/X)_\tau \rightarrow (Sch/Y)_\tau$ becomes a morphism of ringed sites by a map

$$f_{big}^\sharp : \mathcal{O}_Y \longrightarrow f_{big,*}\mathcal{O}_X$$

see Descent, Remark 34.7.4. In fact it is given by the same construction as in the case of small sites explained above.

44.39. Comparing big and small topoi

Let X be a scheme. In Topologies, Lemma 33.4.13 we have introduced comparison morphisms $\pi_X : (Sch/X)_{\acute{e}tale} \rightarrow X_{\acute{e}tale}$ and $i_X : Sh(X_{\acute{e}tale}) \rightarrow Sh((Sch/X)_{\acute{e}tale})$ with $\pi_X \circ i_X = \text{id}$ and $\pi_{X,*} = i_X^{-1}$. In Descent, Remark 34.7.4 we have extended these to a morphism of ringed sites

$$\pi_X : ((Sch/X)_{\acute{e}tale}, \mathcal{O}) \rightarrow (X_{\acute{e}tale}, \mathcal{O}_X)$$

and a morphism of ringed topoi

$$i_X : (Sh(X_{\acute{e}tale}), \mathcal{O}_X) \rightarrow (Sh((Sch/X)_{\acute{e}tale}), \mathcal{O})$$

Note that the restriction $i_X^{-1} = \pi_{X,*}$ (see Topologies, Definition 33.4.14) transforms \mathcal{O} into \mathcal{O}_X . Hence $i_X^*\mathcal{F} = i_X^{-1}\mathcal{F}$ for any \mathcal{O} -module \mathcal{F} on $(Sch/X)_{\acute{e}tale}$. In particular i_X^* is exact. This functor is often denoted $\mathcal{F} \mapsto \mathcal{F}|_{X_{\acute{e}tale}}$.

Lemma 44.39.1. *Let X be a scheme.*

- (1) $\mathcal{I}|_{X_{\acute{e}tale}}$ is injective in $Ab(X_{\acute{e}tale})$ for \mathcal{I} injective in $Ab((Sch/X)_{\acute{e}tale})$, and
- (2) $\mathcal{I}|_{X_{\acute{e}tale}}$ is injective in $Mod(X_{\acute{e}tale}, \mathcal{O}_X)$ for \mathcal{I} injective in $Mod((Sch/X)_{\acute{e}tale}, \mathcal{O})$.

Proof. This follows formally from the fact that the restriction functor $\pi_{X,*} = i_X^{-1}$ is an exact left adjoint of $i_{X,*}$, see Homology, Lemma 12.25.1. □

Let $f : X \rightarrow Y$ be a morphism of schemes. The commutative diagram of Topologies, Lemma 33.4.16 (3) leads to a commutative diagram of ringed sites

$$\begin{array}{ccc} (T_{\acute{e}tale}, \mathcal{O}_T) & \xleftarrow{\pi_T} & ((Sch/T)_{\acute{e}tale}, \mathcal{O}) \\ f_{small} \downarrow & & \downarrow f_{big} \\ (S_{\acute{e}tale}, \mathcal{O}_S) & \xleftarrow{\pi_S} & ((Sch/S)_{\acute{e}tale}, \mathcal{O}) \end{array}$$

as one easily sees by writing out the definitions of f_{small}^\sharp , f_{big}^\sharp , π_S^\sharp , and π_T^\sharp . In particular this means that

$$(44.39.1.1) \quad (f_{big,*}\mathcal{F})|_{Y_{\acute{e}tale}} = f_{small,*}(\mathcal{F}|_{X_{\acute{e}tale}})$$

for any sheaf \mathcal{F} on $(Sch/X)_{\acute{e}tale}$ and if \mathcal{F} is a sheaf of \mathcal{O} -modules, then (44.39.1.1) is an isomorphism of \mathcal{O}_Y -modules on $Y_{\acute{e}tale}$.

Lemma 44.39.2. *Let $f : X \rightarrow Y$ be a morphism of schemes.*

(1) For any $\mathcal{F} \in \text{Ab}((\text{Sch}/X)_{\acute{e}t\text{a}l\text{e}})$ we have

$$(Rf_{\text{big},*}\mathcal{F})|_{Y_{\acute{e}t\text{a}l\text{e}}} = Rf_{\text{small},*}(\mathcal{F}|_{X_{\acute{e}t\text{a}l\text{e}}}).$$

in $D(Y_{\acute{e}t\text{a}l\text{e}})$.

(2) For any object \mathcal{F} of $\text{Mod}((\text{Sch}/X)_{\acute{e}t\text{a}l\text{e}}, \mathcal{O})$ we have

$$(Rf_{\text{big},*}\mathcal{F})|_{Y_{\acute{e}t\text{a}l\text{e}}} = Rf_{\text{small},*}(\mathcal{F}|_{X_{\acute{e}t\text{a}l\text{e}}}).$$

in $D(\text{Mod}(Y_{\acute{e}t\text{a}l\text{e}}, \mathcal{O}_Y))$.

Proof. Follows immediately from Lemma 44.39.1 and (44.39.1.1) on choosing an injective resolution of \mathcal{F} . \square

44.40. Comparing topologies

In this section we start studying what happens when you compare sheaves with respect to different topologies.

Lemma 44.40.1. *Let S be a scheme. Let \mathcal{F} be a sheaf of sets on $S_{\acute{e}t\text{a}l\text{e}}$. Let $s, t \in \mathcal{F}(S)$. Then there exists an open $W \subset S$ characterized by the following property: A morphism $f : T \rightarrow S$ factors through W if and only if $s|_T = t|_T$ (restriction is pullback by f_{small}).*

Proof. Consider the presheaf which assigns to $U \in \text{Ob}(S_{\acute{e}t\text{a}l\text{e}})$ the emptyset if $s|_U \neq t|_U$ and a singleton else. It is clear that this is a subsheaf of the final object of $\text{Sh}(S_{\acute{e}t\text{a}l\text{e}})$. By Lemma 44.31.1 we find an open $W \subset S$ representing this presheaf. For a geometric point \bar{x} of S we see that $\bar{x} \in W$ if and only if the stalks of s and t at \bar{x} agree. By the description of stalks of pullbacks in Lemma 44.36.2 we see that W has the desired property. \square

Lemma 44.40.2. *Let S be a scheme. Let $\tau \in \{\text{Zariski}, \acute{e}t\text{a}l\text{e}\}$. Consider the morphism*

$$\pi : (\text{Sch}/S)_{\tau} \longrightarrow S_{\tau}$$

of Topologies, Lemma 33.3.13 or 33.4.13. Let \mathcal{F} be a sheaf on S_{τ} . Then $\pi^{-1}\mathcal{F}$ is given by the rule

$$\pi^{-1}\mathcal{F}(T) = \Gamma(T_{\tau}, f_{\text{small}}^{-1}\mathcal{F})$$

where $f : T \rightarrow S$. Moreover, $\pi^{-1}\mathcal{F}$ satisfies the sheaf condition with respect to fpqc coverings.

Proof. Observe that we have a morphism $i_f : \text{Sh}(T_{\tau}) \rightarrow \text{Sh}(\text{Sch}/S)_{\tau}$ such that $\pi \circ i_f = f_{\text{small}}$ as morphisms $T_{\tau} \rightarrow S_{\tau}$, see Topologies, Lemmas 33.3.12, 33.3.16, 33.4.12, and 33.4.16. Since pullback is transitive we see that $i_f^{-1}\pi^{-1}\mathcal{F} = f_{\text{small}}^{-1}\mathcal{F}$ as desired.

Let $\{g_i : T_i \rightarrow T\}_{i \in I}$ be an fpqc covering. The final statement means the following: Given a sheaf \mathcal{G} on T_{τ} and given sections $s_i \in \Gamma(T_i, g_{i,\text{small}}^{-1}\mathcal{G})$ whose pullbacks to $T_i \times_T T_j$ agree, there is a unique section s of \mathcal{G} over T whose pullback to T_i agrees with s_i .

Let $V \rightarrow T$ be an object of T_{τ} and let $t \in \mathcal{G}(V)$. For every i there is a largest open $W_i \subset T_i \times_T V$ such that the pullbacks of s_i and t agree as sections of the pullback of \mathcal{G} to $W_i \subset T_i \times_T V$, see Lemma 44.40.1. Because s_i and s_j agree over $T_i \times_T T_j$ we find that W_i and W_j pullback to the same open over $T_i \times_T T_j \times_T V$. By Descent,

Lemma 34.9.2 we find an open $W \subset V$ whose inverse image to $T_i \times_T V$ recovers W_i .

By construction of $g_{i,small}^{-1}\mathcal{G}$ there exists a τ -covering $\{T_{ij} \rightarrow T_i\}_{j \in J_i}$, for each j an open immersion or étale morphism $V_{ij} \rightarrow T$, a section $t_{ij} \in \mathcal{G}(V_{ij})$, and commutative diagrams

$$\begin{array}{ccc} T_{ij} & \longrightarrow & V_{ij} \\ \downarrow & & \downarrow \\ T_i & \longrightarrow & T \end{array}$$

such that $s_i|_{T_{ij}}$ is the pullback of t_{ij} . In other words, after replacing the covering $\{T_i \rightarrow T\}$ by $\{T_{ij} \rightarrow T\}$ we may assume there are factorizations $T_i \rightarrow V_i \rightarrow T$ with $V_i \in \text{Ob}(T_\tau)$ and sections $t_i \in \mathcal{G}(V_i)$ pulling back to s_i over T_i . By the result of the previous paragraph we find opens $W_i \subset V_i$ such that $t_i|_{W_i}$ “agrees with” every s_j over $T_j \times_T W_i$. Note that $T_i \rightarrow V_i$ factors through W_i . Hence $\{W_i \rightarrow T\}$ is a τ -covering and the lemma is proven. \square

Lemma 44.40.3. *Let S be a scheme. Let $f : T \rightarrow S$ be a morphism such that*

- (1) *f is flat and quasi-compact, and*
- (2) *the geometric fibres of f are connected.*

Let \mathcal{F} be a sheaf on $S_{\text{étale}}$. Then $\Gamma(S, \mathcal{F}) = \Gamma(T, f_{small}^{-1}\mathcal{F})$.

Proof. There is a canonical map $\Gamma(S, \mathcal{F}) \rightarrow \Gamma(T, f_{small}^{-1}\mathcal{F})$. Since f is surjective (because its fibres are connected) we see that this map is injective.

To show that the map is surjective, let $\alpha \in \Gamma(T, f_{small}^{-1}\mathcal{F})$. Since $\{T \rightarrow S\}$ is an fpqc covering we can use Lemma 44.40.2 to see that suffices to prove that α pulls back to the same section over $T \times_S T$ by the two projections. Let $\bar{s} \rightarrow S$ be a geometric point. It suffices to show the agreement holds over $(T \times_S T)_{\bar{s}}$ as every geometric point of $T \times_S T$ is contained in one of these geometric fibres. In other words, we are trying to show that $\alpha|_{X_{\bar{s}}}$ pulls back to the same section over $(T \times_S T)_{\bar{s}}$ by the two projections $T_{\bar{s}} \times_{\bar{s}} T_{\bar{s}}$. However, since $\mathcal{F}|_{T_{\bar{s}}}$ is the pullback of $\mathcal{F}|_{\bar{s}}$ it is a constant sheaf with value $\mathcal{F}_{\bar{s}}$. Since $T_{\bar{s}}$ is connected by assumption, any section of a constant sheaf is constant and this proves what we want. \square

Lemma 44.40.4. *Let $k \subset K$ be an extension of fields with k separably algebraically closed. Let S be a scheme over k . Denote $p : S_K = S \times_{\text{Spec}(k)} \text{Spec}(K) \rightarrow S$ the projection. Let \mathcal{F} be a sheaf on $S_{\text{étale}}$. Then $\Gamma(S, \mathcal{F}) = \Gamma(S_K, p_{small}^{-1}\mathcal{F})$.*

Proof. Follows from Lemma 44.40.3. Namely, it is clear that p is flat and quasi-compact as the base change of $\text{Spec}(K) \rightarrow \text{Spec}(k)$. On the other hand, if $\bar{s} : \text{Spec}(L) \rightarrow S$ is a geometric point, then the fibre of p over \bar{s} is the spectrum of $K \otimes_k L$ which is irreducible hence connected by Algebra, Lemma 10.45.4. \square

44.41. Recovering morphisms

In this section we prove that the rule which associates to a scheme its locally ringed small étale topos is fully faithful in a suitable sense, see Theorem 44.41.5.

Lemma 44.41.1. *Let $f : X \rightarrow Y$ be a morphism of schemes. The morphism of ringed sites $(f_{small}, f_{small}^\sharp)$ associated to f is a morphism of locally ringed sites, see Modules on Sites, Definition 18.39.8.*

Proof. Note that the assertion makes sense since we have seen that $(X_{\acute{e}tale}, \mathcal{O}_{X_{\acute{e}tale}})$ and $(Y_{\acute{e}tale}, \mathcal{O}_{Y_{\acute{e}tale}})$ are locally ringed sites, see Lemma 44.33.5. Moreover, we know that $X_{\acute{e}tale}$ has enough points, see Theorem 44.29.10 and Remarks 44.29.11. Hence it suffices to prove that $(f_{small}, f_{small}^\#)$ satisfies condition (3) of Modules on Sites, Lemma 18.39.7. To see this take a point p of $X_{\acute{e}tale}$. By Lemma 44.29.12 p corresponds to a geometric point \bar{x} of X . By Lemma 44.36.2 the point $q = f_{small} \circ p$ corresponds to the geometric point $\bar{y} = f \circ \bar{x}$ of Y . Hence the assertion we have to prove is that the induced map of stalks

$$\mathcal{O}_{Y, \bar{y}} \longrightarrow \mathcal{O}_{X, \bar{x}}$$

is a local ring map. Suppose that $a \in \mathcal{O}_{Y, \bar{y}}$ is an element of the left hand side which maps to an element of the maximal ideal of the right hand side. Suppose that a is the equivalence class of a triple (V, \bar{v}, a) with $V \rightarrow Y$ étale, $\bar{v} : \bar{x} \rightarrow V$ over Y , and $a \in \mathcal{O}(V)$. It maps to the equivalence class of $(X \times_Y V, \bar{x} \times \bar{v}, \text{pr}_V^\#(a))$ in the local ring $\mathcal{O}_{X, \bar{x}}$. But it is clear that being in the maximal ideal means that pulling back $\text{pr}_V^\#(a)$ to an element of $\kappa(\bar{x})$ gives zero. Hence also pulling back a to $\kappa(\bar{x})$ is zero. Which means that a lies in the maximal ideal of $\mathcal{O}_{Y, \bar{y}}$. \square

Lemma 44.41.2. *Let X, Y be schemes. Let $f : X \rightarrow Y$ be a morphism of schemes. Let t be a 2-morphism from $(f_{small}, f_{small}^\#)$ to itself, see Modules on Sites, Definition 18.8.1. Then $t = \text{id}$.*

Proof. This means that $t : f_{small}^{-1} \rightarrow f_{small}^{-1}$ is a transformation of functors such that the diagram

$$\begin{array}{ccc} f_{small}^{-1} \mathcal{O}_Y & \xleftarrow{t} & f_{small}^{-1} \mathcal{O}_Y \\ & \searrow f_{small}^\# & \swarrow f_{small}^\# \\ & \mathcal{O}_X & \end{array}$$

is commutative. Suppose $V \rightarrow Y$ is étale with V affine. By Morphisms, Lemma 28.40.2 we may choose an immersion $i : V \rightarrow \mathbf{A}_Y^n$ over Y . In terms of sheaves this means that i induces an injection $h_i : h_V \rightarrow \prod_{j=1, \dots, n} \mathcal{O}_Y$ of sheaves. The base change i' of i to X is an immersion (Schemes, Lemma 25.18.2). Hence $i' : X \times_Y V \rightarrow \mathbf{A}_X^n$ is an immersion, which in turn means that $h_{i'} : h_{X \times_Y V} \rightarrow \prod_{j=1, \dots, n} \mathcal{O}_X$ is an injection of sheaves. Via the identification $f_{small}^{-1} h_V = h_{X \times_Y V}$ of Lemma 44.36.2 the map $h_{i'}$ is equal to

$$f_{small}^{-1} h_V \xrightarrow{f^{-1} h_i} \prod_{j=1, \dots, n} f_{small}^{-1} \mathcal{O}_Y \xrightarrow{\prod f^\#} \prod_{j=1, \dots, n} \mathcal{O}_X$$

(verification omitted). This means that the map $t : f_{small}^{-1} h_V \rightarrow f_{small}^{-1} h_V$ fits into the commutative diagram

$$\begin{array}{ccccc} f_{small}^{-1} h_V & \xrightarrow{f^{-1} h_i} & \prod_{j=1, \dots, n} f_{small}^{-1} \mathcal{O}_Y & \xrightarrow{\prod f^\#} & \prod_{j=1, \dots, n} \mathcal{O}_X \\ \downarrow t & & \downarrow \prod t & & \downarrow \text{id} \\ f_{small}^{-1} h_V & \xrightarrow{f^{-1} h_i} & \prod_{j=1, \dots, n} f_{small}^{-1} \mathcal{O}_Y & \xrightarrow{\prod f^\#} & \prod_{j=1, \dots, n} \mathcal{O}_X \end{array}$$

The commutativity of the right square holds by our assumption on t explained above. Since the composition of the horizontal arrows is injective by the discussion

above we conclude that the left vertical arrow is the identity map as well. Any sheaf of sets on $Y_{\acute{e}tale}$ admits a surjection from a (huge) coproduct of sheaves of the form h_V with V affine (combine Lemma 44.21.2 with Sites, Lemma 7.13.5). Thus we conclude that $t : f_{small}^{-1} \rightarrow f_{small}^{-1}$ is the identity transformation as desired. \square

Lemma 44.41.3. *Let X, Y be schemes. Any two morphisms $a, b : X \rightarrow Y$ of schemes for which there exists a 2-isomorphism $(a_{small}, a_{small}^\#) \cong (b_{small}, b_{small}^\#)$ in the 2-category of ringed topoi are equal.*

Proof. Let us argue this carefully since it is a bit confusing. Let $t : a_{small}^{-1} \rightarrow b_{small}^{-1}$ be the 2-isomorphism. Consider any open $V \subset Y$. Note that h_V is a subsheaf of the final sheaf $*$. Thus both $a_{small}^{-1}h_V = h_{a^{-1}(V)}$ and $b_{small}^{-1}h_V = h_{b^{-1}(V)}$ are subsheaves of the final sheaf. Thus the isomorphism

$$t : a_{small}^{-1}h_V = h_{a^{-1}(V)} \rightarrow b_{small}^{-1}h_V = h_{b^{-1}(V)}$$

has to be the identity, and $a^{-1}(V) = b^{-1}(V)$. It follows that a and b are equal on underlying topological spaces. Next, take a section $f \in \mathcal{O}_Y(V)$. This determines and is determined by a map of sheaves of sets $f : h_V \rightarrow \mathcal{O}_Y$. Pull this back and apply t to get a commutative diagram

$$\begin{array}{ccccc}
 h_{b^{-1}(V)} & \xlongequal{\quad} & b_{small}^{-1}h_V & \xleftarrow{\quad t \quad} & a_{small}^{-1}h_V & \xlongequal{\quad} & h_{a^{-1}(V)} \\
 & & \downarrow b_{small}^{-1}(f) & & \downarrow a_{small}^{-1}(f) & & \\
 & & b_{small}^{-1}\mathcal{O}_Y & \xleftarrow{\quad t \quad} & a_{small}^{-1}\mathcal{O}_Y & & \\
 & & \searrow b^\# & & \swarrow a^\# & & \\
 & & & & \mathcal{O}_X & &
 \end{array}$$

where the triangle is commutative by definition of a 2-isomorphism in Modules on Sites, Section 18.8. Above we have seen that the composition of the top horizontal arrows comes from the identity $a^{-1}(V) = b^{-1}(V)$. Thus the commutativity of the diagram tells us that $a_{small}^\#(f) = b_{small}^\#(f)$ in $\mathcal{O}_X(a^{-1}(V)) = \mathcal{O}_X(b^{-1}(V))$. Since this holds for every open V and every $f \in \mathcal{O}_Y(V)$ we conclude that $a = b$ as morphisms of schemes. \square

Lemma 44.41.4. *Let X, Y be affine schemes. Let*

$$(g, g^\#) : (\mathit{Sh}(X_{\acute{e}tale}), \mathcal{O}_X) \longrightarrow (\mathit{Sh}(Y_{\acute{e}tale}), \mathcal{O}_Y)$$

be a morphism of locally ringed topoi. Then there exists a unique morphism of schemes $f : X \rightarrow Y$ such that $(g, g^\#)$ is 2-isomorphic to $(f_{small}, f_{small}^\#)$, see Modules on Sites, Definition 18.8.1.

Proof. In this proof we write \mathcal{O}_X for the structure sheaf of the small étale site $X_{\acute{e}tale}$, and similarly for \mathcal{O}_Y . Say $Y = \text{Spec}(B)$ and $X = \text{Spec}(A)$. Since $B = \Gamma(Y_{\acute{e}tale}, \mathcal{O}_Y)$, $A = \Gamma(X_{\acute{e}tale}, \mathcal{O}_X)$ we see that $g^\#$ induces a ring map $\varphi : B \rightarrow A$. Let $f = \text{Spec}(\varphi) : X \rightarrow Y$ be the corresponding morphism of affine schemes. We will show this f does the job.

Let $V \rightarrow Y$ be an affine scheme étale over Y . Thus we may write $V = \text{Spec}(C)$ with C an étale B -algebra. We can write

$$C = B[x_1, \dots, x_n]/(P_1, \dots, P_n)$$

with P_i polynomials such that $\Delta = \det(\partial P_i / \partial x_j)$ is invertible in C , see for example Algebra, Lemma 10.138.2. If T is a scheme over Y , then a T -valued point of V is given by n sections of $\Gamma(T, \mathcal{O}_T)$ which satisfy the polynomial equations $P_1 = 0, \dots, P_n = 0$. In other words, the sheaf h_V on $Y_{\acute{e}tale}$ is the equalizer of the two maps

$$\prod_{i=1, \dots, n} \mathcal{O}_Y \begin{array}{c} \xrightarrow{a} \\ \xrightarrow{b} \end{array} \prod_{j=1, \dots, n} \mathcal{O}_Y$$

where $b(h_1, \dots, h_n) = 0$ and $a(h_1, \dots, h_n) = (P_1(h_1, \dots, h_n), \dots, P_n(h_1, \dots, h_n))$. Since g^{-1} is exact we conclude that the top row of the following solid commutative diagram is an equalizer diagram as well:

$$\begin{array}{ccccc} g^{-1}h_V & \longrightarrow & \prod_{i=1, \dots, n} g^{-1}\mathcal{O}_Y & \begin{array}{c} \xrightarrow{g^{-1}a} \\ \xrightarrow{g^{-1}b} \end{array} & \prod_{j=1, \dots, n} g^{-1}\mathcal{O}_Y \\ \downarrow \text{dotted} & & \downarrow \Pi g^\# & & \downarrow \Pi g^\# \\ h_{X \times_Y V} & \longrightarrow & \prod_{i=1, \dots, n} \mathcal{O}_X & \begin{array}{c} \xrightarrow{a'} \\ \xrightarrow{b'} \end{array} & \prod_{j=1, \dots, n} \mathcal{O}_X \end{array}$$

Here b' is the zero map and a' is the map defined by the images $P'_i = \varphi(P_i) \in A[x_1, \dots, x_n]$ via the same rule $a'(h_1, \dots, h_n) = (P'_1(h_1, \dots, h_n), \dots, P'_n(h_1, \dots, h_n))$, that a was defined by. The commutativity of the diagram follows from the fact that $\varphi = g^\#$ on global sections. The lower row is an equalizer diagram also, by exactly the same arguments as before since $X \times_Y V$ is the affine scheme $\text{Spec}(A \otimes_B C)$ and $A \otimes_B C = A[x_1, \dots, x_n]/(P'_1, \dots, P'_n)$. Thus we obtain a unique dotted arrow $g^{-1}h_V \rightarrow h_{X \times_Y V}$ fitting into the diagram

We claim that the map of sheaves $g^{-1}h_V \rightarrow h_{X \times_Y V}$ is an isomorphism. Since the small étale site of X has enough points (Theorem 44.29.10) it suffices to prove this on stalks. Hence let \bar{x} be a geometric point of X , and denote p the associate point of the small étale topos of X . Set $q = g \circ p$. This is a point of the small étale topos of Y . By Lemma 44.29.12 we see that q corresponds to a geometric point \bar{y} of Y . Consider the map of stalks

$$(g^\#)_p : \mathcal{O}_{Y, \bar{y}} = \mathcal{O}_{Y, q} = (g^{-1}\mathcal{O}_Y)_p \longrightarrow \mathcal{O}_{X, p} = \mathcal{O}_{X, \bar{x}}$$

Since $(g, g^\#)$ is a morphism of *locally* ringed topoi $(g^\#)_p$ is a local ring homomorphism of strictly henselian local rings. Applying localization to the big commutative diagram above and Algebra, Lemma 10.145.31 we conclude that $(g^{-1}h_V)_p \rightarrow (h_{X \times_Y V})_p$ is an isomorphism as desired.

We claim that the isomorphisms $g^{-1}h_V \rightarrow h_{X \times_Y V}$ are functorial. Namely, suppose that $V_1 \rightarrow V_2$ is a morphism of affine schemes étale over Y . Write $V_i = \text{Spec}(C_i)$ with

$$C_i = B[x_{i,1}, \dots, x_{i,n_i}]/(P_{i,1}, \dots, P_{i,n_i})$$

The morphism $V_1 \rightarrow V_2$ is given by a B -algebra map $C_2 \rightarrow C_1$ which in turn is given by some polynomials $Q_j \in B[x_{1,1}, \dots, x_{1,n_1}]$ for $j = 1, \dots, n_2$. Then it is an

easy matter to show that the diagram of sheaves

$$\begin{array}{ccc} h_{V_1} & \longrightarrow & \prod_{i=1, \dots, n_1} \mathcal{O}_Y \\ \downarrow & & \downarrow Q_1, \dots, Q_{n_2} \\ h_{V_2} & \longrightarrow & \prod_{i=1, \dots, n_2} \mathcal{O}_Y \end{array}$$

is commutative, and pulling back to $X_{\acute{e}tale}$ we obtain the solid commutative diagram

$$\begin{array}{ccccc} g^{-1}h_{V_1} & \longrightarrow & \prod_{i=1, \dots, n_1} g^{-1}\mathcal{O}_Y & \xrightarrow{Q_1, \dots, Q_{n_2}} & g^{-1}h_{V_2} & \longrightarrow & \prod_{i=1, \dots, n_2} g^{-1}\mathcal{O}_Y \\ \downarrow \text{dotted} & \searrow & \downarrow g^\sharp & & \downarrow \text{dotted} & & \downarrow g^\sharp \\ h_{X \times_Y V_1} & \longrightarrow & \prod_{i=1, \dots, n_1} \mathcal{O}_X & \xrightarrow{Q'_1, \dots, Q'_{n_2}} & h_{X \times_Y V_2} & \longrightarrow & \prod_{i=1, \dots, n_2} \mathcal{O}_X \end{array}$$

where $Q'_j \in A[x_{1,1}, \dots, x_{1,n_1}]$ is the image of Q_j via φ . Since the dotted arrows exist, make the two squares commute, and the horizontal arrows are injective we see that the whole diagram commutes. This proves functoriality (and also that the construction of $g^{-1}h_V \rightarrow h_{X \times_Y V}$ is independent of the choice of the presentation, although we strictly speaking do not need to show this).

At this point we are able to show that $f_{small,*} \cong g_*$. Namely, let \mathcal{F} be a sheaf on $X_{\acute{e}tale}$. For every $V \in \text{Ob}(X_{\acute{e}tale})$ affine we have

$$\begin{aligned} (g_*\mathcal{F})(V) &= \text{Mor}_{\text{Sh}(Y_{\acute{e}tale})}(h_V, g_*\mathcal{F}) \\ &= \text{Mor}_{\text{Sh}(X_{\acute{e}tale})}(g^{-1}h_V, \mathcal{F}) \\ &= \text{Mor}_{\text{Sh}(X_{\acute{e}tale})}(h_{X \times_Y V}, \mathcal{F}) \\ &= \mathcal{F}(X \times_Y V) \\ &= f_{small,*}\mathcal{F}(V) \end{aligned}$$

where in the third equality we use the isomorphism $g^{-1}h_V \cong h_{X \times_Y V}$ constructed above. These isomorphisms are clearly functorial in \mathcal{F} and functorial in V as the isomorphisms $g^{-1}h_V \cong h_{X \times_Y V}$ are functorial. Now any sheaf on $Y_{\acute{e}tale}$ is determined by the restriction to the subcategory of affine schemes (Lemma 44.21.2), and hence we obtain an isomorphism of functors $f_{small,*} \cong g_*$ as desired.

Finally, we have to check that, via the isomorphism $f_{small,*} \cong g_*$ above, the maps f_{small}^\sharp and g^\sharp agree. By construction this is already the case for the global sections of \mathcal{O}_Y , i.e., for the elements of B . We only need to check the result on sections over an affine V étale over Y (by Lemma 44.21.2 again). Writing $V = \text{Spec}(C)$, $C = B[x_i]/(P_j)$ as before it suffices to check that the coordinate functions x_i are mapped to the same sections of \mathcal{O}_X over $X \times_Y V$. And this is exactly what it

means that the diagram

$$\begin{array}{ccc} g^{-1}h_V & \longrightarrow & \prod_{i=1, \dots, n} g^{-1}\mathcal{O}_Y \\ \downarrow \text{dotted} & & \downarrow \Pi g^\sharp \\ h_{X \times_Y V} & \longrightarrow & \prod_{i=1, \dots, n} \mathcal{O}_X \end{array}$$

commutes. Thus the lemma is proved. □

Here is a version for general schemes.

Theorem 44.41.5. *Let X, Y be schemes. Let*

$$(g, g^\sharp) : (Sh(X_{\acute{e}tale}), \mathcal{O}_X) \longrightarrow (Sh(Y_{\acute{e}tale}), \mathcal{O}_Y)$$

be a morphism of locally ringed topoi. Then there exists a unique morphism of schemes $f : X \rightarrow Y$ such that (g, g^\sharp) is isomorphic to $(f_{small}, f_{small}^\sharp)$. In other words, the construction

$$Sch \longrightarrow \text{Locally ringed topoi}, \quad X \longrightarrow (X_{\acute{e}tale}, \mathcal{O}_X)$$

is fully faithful (morphisms up to 2-isomorphisms on the right hand side).

Proof. You can prove this theorem by carefully adjusting the arguments of the proof of Lemma 44.41.4 to the global setting. However, we want to indicate how we can glue the result of that lemma to get a global morphism due to the rigidity provided by the result of Lemma 44.41.2. Unfortunately, this is a bit messy.

Let us prove existence when Y is affine. In this case choose an affine open covering $X = \bigcup U_i$. For each i the inclusion morphism $j_i : U_i \rightarrow X$ induces a morphism of locally ringed topoi $(j_{i,small}, j_{i,small}^\sharp) : (Sh(U_{i,\acute{e}tale}), \mathcal{O}_{U_i}) \rightarrow (Sh(X_{\acute{e}tale}), \mathcal{O}_X)$ by Lemma 44.41.1. We can compose this with (g, g^\sharp) to obtain a morphism of locally ringed topoi

$$(g, g^\sharp) \circ (j_{i,small}, j_{i,small}^\sharp) : (Sh(U_{i,\acute{e}tale}), \mathcal{O}_{U_i}) \rightarrow (Sh(X_{\acute{e}tale}), \mathcal{O}_X)$$

see Modules on Sites, Lemma 18.39.9. By Lemma 44.41.4 there exists a unique morphism of schemes $f_i : U_i \rightarrow Y$ and a 2-isomorphism

$$t_i : (f_{i,small}, f_{i,small}^\sharp) \longrightarrow (g, g^\sharp) \circ (j_{i,small}, j_{i,small}^\sharp).$$

Set $U_{i,i'} = U_i \cap U_{i'}$, and denote $j_{i,i'} : U_{i,i'} \rightarrow U_i$ the inclusion morphism. Since we have $j_i \circ j_{i,i'} = j_{i',i} \circ j_{i',i}$ we see that

$$\begin{aligned} (g, g^\sharp) \circ (j_{i,small}, j_{i,small}^\sharp) \circ (j_{i,i',small}, j_{i,i',small}^\sharp) &= \\ (g, g^\sharp) \circ (j_{i',small}, j_{i',small}^\sharp) \circ (j_{i',i,small}, j_{i',i,small}^\sharp) & \end{aligned}$$

Hence by uniqueness (see Lemma 44.41.3) we conclude that $f_i \circ j_{i,i'} = f_{i'} \circ j_{i',i}$, in other words the morphisms of schemes $f_i = f \circ j_i$ are the restrictions of a global morphism of schemes $f : X \rightarrow Y$. Consider the diagram of 2-isomorphisms (where we drop the components $^\sharp$ to ease the notation)

$$\begin{array}{ccc} g \circ j_{i,small} \circ j_{i,i',small} & \xrightarrow{t_i \star \text{id}_{j_{i,i',small}}} & f_{small} \circ j_{i,small} \circ j_{i,i',small} \\ \parallel & & \parallel \\ g \circ j_{i',small} \circ j_{i',i,small} & \xrightarrow{t_{i'} \star \text{id}_{j_{i',i,small}}} & f_{small} \circ j_{i',small} \circ j_{i',i,small} \end{array}$$

The notation \star indicates horizontal composition, see Categories, Definition 4.27.1 in general and Sites, Section 7.35 for our particular case. By the result of Lemma 44.41.2 this diagram commutes. Hence for any sheaf \mathcal{G} on $Y_{\acute{e}tale}$ the isomorphisms $t_i : f_{small}^{-1}\mathcal{G}|_{U_i} \rightarrow g^{-1}\mathcal{G}|_{U_i}$ agree over $U_{i,i'}$ and we obtain a global isomorphism $t : f_{small}^{-1}\mathcal{G} \rightarrow g^{-1}\mathcal{G}$. It is clear that this isomorphism is functorial in \mathcal{G} and is compatible with the maps f_{small}^\sharp and g^\sharp (because it is compatible with these maps locally). This proves the theorem in case Y is affine.

In the general case, let $V \subset Y$ be an affine open. Then h_V is a subsheaf of the final sheaf $*$ on $Y_{\acute{e}tale}$. As g is exact we see that $g^{-1}h_V$ is a subsheaf of the final sheaf on $X_{\acute{e}tale}$. Hence by Lemma 44.31.1 there exists an open subscheme $W \subset X$ such that $g^{-1}h_V = h_W$. By Modules on Sites, Lemma 18.39.11 there exists a commutative diagram of morphisms of locally ringed topoi

$$\begin{CD} (Sh(W_{\acute{e}tale}), \mathcal{O}_W) @>>> (Sh(X_{\acute{e}tale}), \mathcal{O}_X) \\ @V g' VV @VV g V \\ (Sh(V_{\acute{e}tale}), \mathcal{O}_V) @>>> (Sh(Y_{\acute{e}tale}), \mathcal{O}_Y) \end{CD}$$

where the horizontal arrows are the localization morphisms (induced by the inclusion morphisms $V \rightarrow Y$ and $W \rightarrow X$) and where g' is induced from g . By the result of the preceding paragraph we obtain a morphism of schemes $f' : W \rightarrow V$ and a 2-isomorphism $t : (f'_{small}, (f'_{small})^\sharp) \rightarrow (g', (g')^\sharp)$. Exactly as before these morphisms f' (for varying affine opens $V \subset Y$) agree on overlaps by uniqueness, so we get a morphism $f : X \rightarrow Y$. Moreover, the 2-isomorphisms t are compatible on overlaps by Lemma 44.41.2 again and we obtain a global 2-isomorphism $(f_{small}, (f_{small})^\sharp) \rightarrow (g, (g)^\sharp)$. as desired. Some details omitted. \square

44.42. Push and pull

Let $f : X \rightarrow Y$ be a morphism of schemes. Here is a list of conditions we will consider in the following:

- (A) For every étale morphism $U \rightarrow X$ and $u \in U$ there exist an étale morphism $V \rightarrow Y$ and a disjoint union decomposition $X \times_Y V = W \amalg W'$ and a morphism $h : W \rightarrow U$ over X with u in the image of h .
- (B) For every $V \rightarrow Y$ étale, and every étale covering $\{U_i \rightarrow X \times_Y V\}$ there exists an étale covering $\{V_j \rightarrow V\}$ such that for each j we have $X \times_Y V_j = \coprod W_{ji}$ where $W_{ij} \rightarrow X \times_Y V$ factors through $U_i \rightarrow X \times_Y V$ for some i .
- (C) For every $U \rightarrow X$ étale, there exists a $V \rightarrow Y$ étale and a surjective morphism $X \times_Y V \rightarrow U$ over X .

It turns out that each of these properties has meaning in terms of the behaviour of the functor $f_{small,*}$. We will work this out in the next few sections.

44.43. Property (A)

Please see Section 44.42 for the definition of property (A).

Lemma 44.43.1. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume (A).*

- (1) $f_{small,*} : Ab(X_{\acute{e}tale}) \rightarrow Ab(Y_{\acute{e}tale})$ reflects injections and surjections,
- (2) $f_{small}^{-1}f_{small,*}\mathcal{F} \rightarrow \mathcal{F}$ is surjective for any abelian sheaf \mathcal{F} on $X_{\acute{e}tale}$,
- (3) $f_{small,*} : Ab(X_{\acute{e}tale}) \rightarrow Ab(Y_{\acute{e}tale})$ is faithful.

Proof. Let \mathcal{F} be an abelian sheaf on $X_{\acute{e}tale}$. Let U be an object of $X_{\acute{e}tale}$. By assumption we can find a covering $\{W_i \rightarrow U\}$ in $X_{\acute{e}tale}$ such that each W_i is an open and closed subscheme of $X \times_Y V_i$ for some object V_i of $Y_{\acute{e}tale}$. The sheaf condition shows that

$$\mathcal{F}(U) \subset \prod \mathcal{F}(W_i)$$

and that $\mathcal{F}(W_i)$ is a direct summand of $\mathcal{F}(X \times_Y V_i) = f_{small,*}\mathcal{F}(V_i)$. Hence it is clear that $f_{small,*}$ reflects injections.

Next, suppose that $a : \mathcal{G} \rightarrow \mathcal{F}$ is a map of abelian sheaves such that $f_{small,*}a$ is surjective. Let $s \in \mathcal{F}(U)$ with U as above. With W_i, V_i as above we see that it suffices to show that $s|_{W_i}$ is étale locally the image of a section of \mathcal{G} under a . Since $\mathcal{F}(W_i)$ is a direct summand of $\mathcal{F}(X \times_Y V_i)$ it suffices to show that for any $V \in \text{Ob}(Y_{\acute{e}tale})$ any element $s \in \mathcal{F}(X \times_Y V)$ is étale locally on $X \times_Y V$ the image of a section of \mathcal{G} under a . Since $\mathcal{F}(X \times_Y V) = f_{small,*}\mathcal{F}(V)$ we see by assumption that there exists a covering $\{V_j \rightarrow V\}$ such that s is the image of $s_j \in f_{small,*}\mathcal{G}(V_j) = \mathcal{G}(X \times_Y V_j)$. This proves $f_{small,*}$ reflects surjections.

Parts (2), (3) follow formally from part (1), see Modules on Sites, Lemma 18.15.1. □

Lemma 44.43.2. *Let $f : X \rightarrow Y$ be a separated locally quasi-finite morphism of schemes. Then property (A) above holds.*

Proof. Let $U \rightarrow X$ be an étale morphism and $u \in U$. The geometric statement (A) reduces directly to the case where U and Y are affine schemes. Denote $x \in X$ and $y \in Y$ the images of u . Since $X \rightarrow Y$ is locally quasi-finite, and $U \rightarrow X$ is locally quasi-finite (see Morphisms, Lemma 28.37.6) we see that $U \rightarrow Y$ is locally quasi-finite (see Morphisms, Lemma 28.21.12). Moreover both $X \rightarrow Y$ and $U \rightarrow Y$ are separated. Thus More on Morphisms, Lemma 36.30.5 applies to both morphisms. This means we may pick an étale neighbourhood $(V, v) \rightarrow (Y, y)$ such that

$$X \times_Y V = W \amalg R, \quad U \times_Y V = W' \amalg R'$$

and points $w \in W, w' \in W'$ such that

- (1) W, R are open and closed in $X \times_Y V$,
- (2) W', R' are open and closed in $U \times_Y V$,
- (3) $W \rightarrow V$ and $W' \rightarrow V$ are finite,
- (4) w, w' map to v ,
- (5) $\kappa(v) \subset \kappa(w)$ and $\kappa(v) \subset \kappa(w')$ are purely inseparable, and
- (6) no other point of W or W' maps to v .

Here is a commutative diagram

$$\begin{array}{ccccc} U & \longleftarrow & U \times_Y V & \longleftarrow & W' \amalg R' \\ \downarrow & & \downarrow & & \downarrow \\ X & \longleftarrow & X \times_Y V & \longleftarrow & W \amalg R \\ \downarrow & & \downarrow & & \\ Y & \longleftarrow & V & & \end{array}$$

After shrinking V we may assume that W' maps into W : just remove the image the inverse image of R in W' ; this is a closed set (as $W' \rightarrow V$ is finite) not containing

v . Then $W' \rightarrow W$ is finite because both $W \rightarrow V$ and $W' \rightarrow V$ are finite. Hence $W' \rightarrow W$ is finite étale, and there is exactly one point in the fibre over w with $\kappa(w) = \kappa(w')$. Hence $W' \rightarrow W$ is an isomorphism in an open neighbourhood W° of w , see Étale Morphisms, Lemma 40.14.2. Since $W \rightarrow V$ is finite the image of $W \setminus W^\circ$ is a closed subset T of V not containing v . Thus after replacing V by $V \setminus T$ we may assume that $W' \rightarrow W$ is an isomorphism. Now the decomposition $X \times_Y V = W \amalg R$ and the morphism $W \rightarrow U$ are as desired and we win. \square

Lemma 44.43.3. *Let $f : X \rightarrow Y$ be an integral morphism of schemes. Then property (A) holds.*

Proof. Let $U \rightarrow X$ be étale, and let $u \in U$ be a point. We have to find $V \rightarrow Y$ étale, a disjoint union decomposition $X \times_Y V = W \amalg W'$ and an X -morphism $W \rightarrow U$ with u in the image. We may shrink U and Y and assume U and Y are affine. In this case also X is affine, since an integral morphism is affine by definition. Write $Y = \text{Spec}(A)$, $X = \text{Spec}(B)$ and $U = \text{Spec}(C)$. Then $A \rightarrow B$ is an integral ring map, and $B \rightarrow C$ is an étale ring map. By Algebra, Lemma 10.138.3 we can find a finite A -subalgebra $B' \subset B$ and an étale ring map $B' \rightarrow C'$ such that $C = B \otimes_{B'} C'$. Thus the question reduces to the étale morphism $U' = \text{Spec}(C') \rightarrow X' = \text{Spec}(B')$ over the finite morphism $X' \rightarrow Y$. In this case the result follows from Lemma 44.43.2. \square

Lemma 44.43.4. *Let $f : X \rightarrow Y$ be a morphism of schemes. Denote $f_{\text{small}} : \text{Sh}(X_{\text{étale}}) \rightarrow \text{Sh}(Y_{\text{étale}})$ the associated morphism of small étale topoi. Assume at least one of the following*

- (1) f is integral, or
- (2) f is separated and locally quasi-finite.

Then the functor $f_{\text{small},} : \text{Ab}(X_{\text{étale}}) \rightarrow \text{Ab}(Y_{\text{étale}})$ has the following properties*

- (1) *the map $f_{\text{small},*}^{-1} f_{\text{small},*} \mathcal{F} \rightarrow \mathcal{F}$ is always surjective,*
- (2) *$f_{\text{small},*}$ is faithful, and*
- (3) *$f_{\text{small},*}$ reflects injections and surjections.*

Proof. Combine Lemmas 44.43.2, 44.43.3, and 44.43.1. \square

44.44. Property (B)

Please see Section 44.42 for the definition of property (B).

Lemma 44.44.1. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume (B) holds. Then the functor $f_{\text{small},*} : \text{Sh}(X_{\text{étale}}) \rightarrow \text{Sh}(Y_{\text{étale}})$ transforms surjections into surjections.*

Proof. This follows from Sites, Lemma 7.40.2. \square

Lemma 44.44.2. *Let $f : X \rightarrow Y$ be a morphism of schemes. Suppose*

- (1) $V \rightarrow Y$ is an étale morphism of schemes,
- (2) $\{U_i \rightarrow X \times_Y V\}$ is an étale covering, and
- (3) $v \in V$ is a point.

Assume that for any such data there exists an étale neighbourhood $(V', v') \rightarrow (V, v)$, a disjoint union decomposition $X \times_Y V' = \coprod W'_i$, and morphisms $W'_i \rightarrow U_i$ over $X \times_Y V$. Then property (B) holds.

Proof. Omitted. □

Lemma 44.44.3. *Let $f : X \rightarrow Y$ be a finite morphism of schemes. Then property (B) holds.*

Proof. Consider $V \rightarrow Y$ étale, $\{U_i \rightarrow X \times_Y V\}$ an étale covering, and $v \in V$. We have to find a $V' \rightarrow V$ and decomposition and maps as in Lemma 44.44.2. We may shrink V and Y , hence we may assume that V and Y are affine. Since X is finite over Y , this also implies that X is affine. During the proof we may (finitely often) replace (V, v) by an étale neighbourhood (V', v') and correspondingly the covering $\{U_i \rightarrow X \times_Y V\}$ by $\{V' \times_V U_i \rightarrow X \times_Y V'\}$.

Since $X \times_Y V \rightarrow V$ is finite there exist finitely many (pairwise distinct) points $x_1, \dots, x_n \in X \times_Y V$ mapping to v . We may apply More on Morphisms, Lemma 36.30.5 to $X \times_Y V \rightarrow V$ and the points x_1, \dots, x_n lying over v and find an étale neighbourhood $(V', v') \rightarrow (V, v)$ such that

$$X \times_Y V' = R \amalg \coprod T_a$$

with $T_a \rightarrow V'$ finite with exactly one point p_a lying over v' and moreover $\kappa(v') \subset \kappa(p_a)$ purely inseparable, and such that $R \rightarrow V'$ has empty fibre over v' . Because $X \rightarrow Y$ is finite, also $R \rightarrow V'$ is finite. Hence after shrinking V' we may assume that $R = \emptyset$. Thus we may assume that $X \times_Y V' = X_1 \amalg \dots \amalg X_n$ with exactly one point $x_l \in X_l$ lying over v with moreover $\kappa(v) \subset \kappa(x_l)$ purely inseparable. Note that this property is preserved under refinement of the étale neighbourhood (V, v) .

For each l choose an i_l and a point $u_l \in U_{i_l}$ mapping to x_l . Now we apply property (A) for the finite morphism $X \times_Y V \rightarrow V$ and the étale morphisms $U_{i_l} \rightarrow X \times_Y V$ and the points u_l . This is permissible by Lemma 44.43.3 This gives produces an étale neighbourhood $(V', v') \rightarrow (V, v)$ and decompositions

$$X \times_Y V' = W_l \amalg R_l$$

and X -morphisms $a_l : W_l \rightarrow U_{i_l}$ whose image contains u_{i_l} . Here is a picture:

$$\begin{array}{ccccccc}
 & & & & & & U_{i_l} \\
 & & & & & & \downarrow \\
 & & & & & & \downarrow \\
 W_l & \xrightarrow{\quad} & W_l \amalg R_l & \xrightarrow{=} & X \times_Y V' & \longrightarrow & X \times_Y V & \longrightarrow & X \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 & & V' & \longrightarrow & V & \longrightarrow & Y
 \end{array}$$

After replacing (V, v) by (V', v') we conclude that each x_l is contained in an open and closed neighbourhood W_l such that the inclusion morphism $W_l \rightarrow X \times_Y V$ factors through $U_{i_l} \rightarrow X \times_Y V$ for some i . Replacing W_l by $W_l \cap X_l$ we see that these open and closed sets are disjoint and moreover that $\{x_1, \dots, x_n\} \subset W_1 \cup \dots \cup W_n$. Since $X \times_Y V \rightarrow V$ is finite we may shrink V and assume that $X \times_Y V = W_1 \amalg \dots \amalg W_n$ as desired. □

Lemma 44.44.4. *Let $f : X \rightarrow Y$ be an integral morphism of schemes. Then property (B) holds.*

Proof. Consider $V \rightarrow Y$ étale, $\{U_i \rightarrow X \times_Y V\}$ an étale covering, and $v \in V$. We have to find a $V' \rightarrow V$ and decomposition and maps as in Lemma 44.44.2. We may shrink V and Y , hence we may assume that V and Y are affine. Since X is integral over Y , this also implies that X and $X \times_Y V$ are affine. We may refine the covering $\{U_i \rightarrow X \times_Y V\}$, and hence we may assume that $\{U_i \rightarrow X \times_Y V\}_{i=1, \dots, n}$ is a standard étale covering. Write $Y = \text{Spec}(A)$, $X = \text{Spec}(B)$, $V = \text{Spec}(C)$, and $U_i = \text{Spec}(B_i)$. Then $A \rightarrow B$ is an integral ring map, and $B \otimes_A C \rightarrow B_i$ are étale ring maps. By Algebra, Lemma 10.138.3 we can find a finite A -subalgebra $B' \subset B$ and an étale ring map $B' \otimes_A C \rightarrow B'_i$ for $i = 1, \dots, n$ such that $B_i = B \otimes_{B'} B'_i$. Thus the question reduces to the étale covering $\{\text{Spec}(B'_i) \rightarrow X' \times_Y V\}_{i=1, \dots, n}$ with $X' = \text{Spec}(B')$ finite over Y . In this case the result follows from Lemma 44.44.3. \square

Lemma 44.44.5. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume f is integral (for example finite). Then*

- (1) $f_{small,*}$ transforms surjections into surjections (on sheaves of sets and on abelian sheaves),
- (2) $f_{small}^{-1} f_{small,*} \mathcal{F} \rightarrow \mathcal{F}$ is surjective for any abelian sheaf \mathcal{F} on $X_{\text{étale}}$,
- (3) $f_{small,*} : \text{Ab}(X_{\text{étale}}) \rightarrow \text{Ab}(Y_{\text{étale}})$ is faithful and reflects injections and surjections, and
- (4) $f_{small,*} : \text{Ab}(X_{\text{étale}}) \rightarrow \text{Ab}(Y_{\text{étale}})$ is exact.

Proof. Parts (2), (3) we have seen in Lemma 44.43.4. Part (1) follows from Lemmas 44.44.4 and 44.44.1. Part (4) is a consequence of part (1), see Modules on Sites, Lemma 18.15.2. \square

44.45. Property (C)

Please see Section 44.42 for the definition of property (C).

Lemma 44.45.1. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume (C) holds. Then the functor $f_{small,*} : \text{Sh}(X_{\text{étale}}) \rightarrow \text{Sh}(Y_{\text{étale}})$ reflects injections and surjections.*

Proof. Follows from Sites, Lemma 7.40.4. We omit the verification that property (C) implies that the functor $Y_{\text{étale}} \rightarrow X_{\text{étale}}$, $V \mapsto X \times_Y V$ satisfies the assumption of Sites, Lemma 7.40.4. \square

Remark 44.45.2. Property (C) holds if $f : X \rightarrow Y$ is an open immersion. Namely, if $U \in \text{Ob}(X_{\text{étale}})$, then we can view U also as an object of $Y_{\text{étale}}$ and $U \times_Y X = U$. Hence property (C) does not imply that $f_{small,*}$ is exact as this is not the case for open immersions (in general).

Lemma 44.45.3. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume that for any $V \rightarrow Y$ étale we have that*

- (1) $X \times_Y V \rightarrow V$ has property (C), and
- (2) $X \times_Y V \rightarrow V$ is closed.

Then the functor $Y_{\text{étale}} \rightarrow X_{\text{étale}}$, $V \mapsto X \times_Y V$ is almost cocontinuous, see Sites, Definition 7.41.3.

Proof. Let $V \rightarrow Y$ be an object of $Y_{\text{étale}}$ and let $\{U_i \rightarrow X \times_Y V\}_{i \in I}$ be a covering of $X_{\text{étale}}$. By assumption (1) for each i we can find an étale morphism $h_i : V_i \rightarrow V$

and a surjective morphism $X \times_Y V_i \rightarrow U_i$ over $X \times_Y V$. Note that $\bigcup h_i(V_i) \subset V$ is an open set containing the closed set $Z = \text{Im}(X \times_Y V \rightarrow V)$. Let $h_0 : V_0 = V \setminus Z \rightarrow V$ be the open immersion. It is clear that $\{V_i \rightarrow V\}_{i \in I \cup \{0\}}$ is an étale covering such that for each $i \in I \cup \{0\}$ we have either $V_i \times_Y X = \emptyset$ (namely if $i = 0$), or $V_i \times_Y X \rightarrow V \times_Y X$ factors through $U_i \rightarrow X \times_Y V$ (if $i \neq 0$). Hence the functor $Y_{\text{étale}} \rightarrow X_{\text{étale}}$ is almost cocontinuous. \square

Lemma 44.45.4. *Let $f : X \rightarrow Y$ be an integral morphism of schemes which defines a homeomorphism of X with a closed subset of Y . Then property (C) holds.*

Proof. Let $g : U \rightarrow X$ be an étale morphism. We need to find an object $V \rightarrow Y$ of $Y_{\text{étale}}$ and a surjective morphism $X \times_Y V \rightarrow U$ over X . Suppose that for every $u \in U$ we can find an object $V_u \rightarrow Y$ of $Y_{\text{étale}}$ and a morphism $h_u : X \times_Y V_u \rightarrow U$ over X with $u \in \text{Im}(h_u)$. Then we can take $V = \coprod V_u$ and $h = \coprod h_u$ and we win. Hence given a point $u \in U$ we find a pair (V_u, h_u) as above. To do this we may shrink U and assume that U is affine. In this case $g : U \rightarrow X$ is locally quasi-finite. Let $g^{-1}(g(\{u\})) = \{u, u_2, \dots, u_n\}$. Since there are no specializations $u_i \rightsquigarrow u$ we may replace U by an affine neighbourhood so that $g^{-1}(g(\{u\})) = \{u\}$.

The image $g(U) \subset X$ is open, hence $f(g(U))$ is locally closed in Y . Choose an open $V \subset Y$ such that $f(g(U)) = f(X) \cap V$. It follows that g factors through $X \times_Y V$ and that the resulting $\{U \rightarrow X \times_Y V\}$ is an étale covering. Since f has property (B), see Lemma 44.44.4, we see that there exists an étale covering $\{V_j \rightarrow V\}$ such that $X \times_Y V_j \rightarrow X \times_Y V$ factor through U . This implies that $V' = \coprod V_j$ is étale over Y and that there is a morphism $h : X \times_Y V' \rightarrow U$ whose image surjects onto $g(U)$. Since u is the only point in its fibre it must be in the image of h and we win. \square

We urge the reader to think of the following lemma as a way station³ on the journey towards the ultimate truth regarding $f_{\text{small},*}$ for integral universally injective morphisms.

Lemma 44.45.5. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume that f is universally injective and integral (for example a closed immersion). Then*

- (1) $f_{\text{small},*} : \text{Sh}(X_{\text{étale}}) \rightarrow \text{Sh}(Y_{\text{étale}})$ reflects injections and surjections,
- (2) $f_{\text{small},*} : \text{Sh}(X_{\text{étale}}) \rightarrow \text{Sh}(Y_{\text{étale}})$ commutes with pushouts and coequalizers (and more generally finite connected colimits),
- (3) $f_{\text{small},*}$ transforms surjections into surjections (on sheaves of sets and on abelian sheaves),
- (4) the map $f_{\text{small},*}^{-1} f_{\text{small},*} \mathcal{F} \rightarrow \mathcal{F}$ is surjective for any sheaf (of sets or of abelian groups) \mathcal{F} on $X_{\text{étale}}$,
- (5) the functor $f_{\text{small},*}$ is faithful (on sheaves of sets and on abelian sheaves),
- (6) $f_{\text{small},*} : \text{Ab}(X_{\text{étale}}) \rightarrow \text{Ab}(Y_{\text{étale}})$ is exact, and
- (7) the functor $Y_{\text{étale}} \rightarrow X_{\text{étale}}, V \mapsto X \times_Y V$ is almost cocontinuous.

Proof. By Lemmas 44.43.3, 44.44.4 and 44.45.4 we know that the morphism f has properties (A), (B), and (C). Moreover, by Lemma 44.45.3 we know that the functor $Y_{\text{étale}} \rightarrow X_{\text{étale}}$ is almost cocontinuous. Now we have

- (1) property (C) implies (1) by Lemma 44.45.1,
- (2) almost continuous implies (2) by Sites, Lemma 7.41.6,

³A way station is a place where people stop to eat and rest when they are on a long journey.

(3) property (B) implies (3) by Lemma 44.44.1.

Properties (4), (5), and (6) follow formally from the first three, see Sites, Lemma 7.40.1 and Modules on Sites, Lemma 18.15.2. Property (7) we saw above. \square

44.46. Topological invariance of the small étale site

In the following theorem we show that the small étale site is a topological invariant in the following sense: If $f : X \rightarrow Y$ is a morphism of schemes which is a universal homeomorphism, then $X_{\text{étale}} \cong Y_{\text{étale}}$ as sites. This improves the result of Étale Morphisms, Theorem 40.15.2.

Theorem 44.46.1. *Let $f : X \rightarrow Y$ be a morphism of schemes. Assume f is integral, universally injective and surjective (i.e., f is a universal homeomorphism, see Morphisms, Lemma 28.45.3). The functor*

$$V \mapsto V_X = X \times_Y V$$

defines an equivalence of categories

$$\{\text{schemes } V \text{ étale over } Y\} \leftrightarrow \{\text{schemes } U \text{ étale over } X\}$$

Proof. We claim that it suffices to prove that the functor defines an equivalence

$$(44.46.1.1) \quad \{\text{affine schemes } V \text{ étale over } Y\} \leftrightarrow \{\text{affine schemes } U \text{ étale over } X\}$$

when X and Y are affine. We omit the proof of this claim.

Assume X and Y affine. Let us prove (44.46.1.1) is fully faithful. Suppose that V, V' are affine schemes étale over Y , and that $\varphi : V_X \rightarrow V'_X$ is a morphism over X . To prove that $\varphi = \psi_X$ for some $\psi : V \rightarrow V'$ over Y we may work locally on V . The graph

$$\Gamma_\varphi \subset (V \times_Y V')_X$$

of φ is an open and closed subscheme, see Étale Morphisms, Proposition 40.6.1. Since f is a universal homeomorphism we see that there exists an open and closed subscheme $\Gamma \subset V \times_Y V'$ with $\Gamma_X = \Gamma_\varphi$. We see that Γ is an affine scheme endowed with an étale, universally injective, and surjective morphism $\Gamma \rightarrow V$. This implies that $\Gamma \rightarrow V$ is an isomorphism (see Étale Morphisms, Theorem 40.14.1), and hence Γ is the graph of a morphism $\psi : V \rightarrow V'$ over Y as desired.

Let us prove (44.46.1.1) is essentially surjective. Let $U \rightarrow X$ be an affine scheme étale over X . We have to find $V \rightarrow Y$ étale (and affine) such that $X \times_Y V$ is isomorphic to U over X . Note that an étale morphism of affines has universally bounded fibres, see Morphisms, Lemmas 28.37.6 and 28.50.8. Hence we can do induction on the integer n bounding the degree of the fibres of $U \rightarrow X$. See Morphisms, Lemma 28.50.7 for a description of this integer in the case of an étale morphism. If $n = 1$, then $U \rightarrow X$ is an open immersion (see Étale Morphisms, Theorem 40.14.1), and the result is clear. Assume $n > 1$.

By Lemma 44.45.4 there exists an étale morphism of schemes $W \rightarrow Y$ and a surjective morphism $W_X \rightarrow U$ over X . As U is quasi-compact we may replace W by a disjoint union of finitely many affine opens of W , hence we may assume that

W is affine as well. Here is a diagram

$$\begin{array}{ccccc}
 U & \longleftarrow & U \times_Y W & \xlongequal{\quad} & W_X \amalg R \\
 \downarrow & & \downarrow & & \downarrow \\
 X & \longleftarrow & W_X & & \\
 \downarrow & & \downarrow & & \downarrow \\
 Y & \longleftarrow & W & &
 \end{array}$$

The disjoint union decomposition arises because by construction the étale morphism of affine schemes $U \times_Y W \rightarrow W_X$ has a section. OK, and now we see that the morphism $R \rightarrow X \times_Y W$ is an étale morphism of affine schemes whose fibres have degree universally bounded by $n - 1$. Hence by induction assumption there exists a scheme $V' \rightarrow W$ étale such that $R \cong W_X \times_W V'$. Taking $V'' = W \amalg V'$ we find a scheme V'' étale over W whose base change to W_X is isomorphic to $U \times_Y W$ over $X \times_Y W$.

At this point we can use descent to find V over Y whose base change to X is isomorphic to U over X . Namely, by the fully faithfulness of the functor (44.46.1.1) corresponding to the universal homeomorphism $X \times_Y (W \times_Y W) \rightarrow (W \times_Y W)$ there exists a unique isomorphism $\varphi : V'' \times_Y W \rightarrow W \times_Y V''$ whose base change to $X \times_Y (W \times_Y W)$ is the canonical descent datum for $U \times_Y W$ over $X \times_Y W$. In particular φ satisfies the cocycle condition. Hence by Descent, Lemma 34.33.1 we see that φ is effective (recall that all schemes above are affine). Thus we obtain $V \rightarrow Y$ and an isomorphism $V'' \cong W \times_Y V$ such that the canonical descent datum on $W \times_Y V/W/Y$ agrees with φ . Note that $V \rightarrow Y$ is étale, by Descent, Lemma 34.19.27. Moreover, there is an isomorphism $V_X \cong U$ which comes from descending the isomorphism

$$V_X \times_X W_X = X \times_Y V \times_Y W = (X \times_Y W) \times_W (W \times_Y V) \cong W_X \times_W V'' \cong U \times_Y W$$

which we have by construction. Some details omitted. □

Remark 44.46.2. In the situation of Theorem 44.46.1 it is also true that $V \mapsto V_X$ induces an equivalence between those étale morphisms $V \rightarrow Y$ with V affine and those étale morphisms $U \rightarrow X$ with U affine. This follows for example from Limits, Proposition 31.10.2.

Proposition 44.46.3 (Topological invariance of étale cohomology). *Let $X_0 \rightarrow X$ be a universal homeomorphism of schemes (for example the closed immersion defined by a nilpotent sheaf of ideals). Then*

- (1) *the étale sites $X_{\text{étale}}$ and $(X_0)_{\text{étale}}$ are isomorphic,*
- (2) *the étale topoi $Sh(X_{\text{étale}})$ and $Sh((X_0)_{\text{étale}})$ are equivalent, and*
- (3) *$H_{\text{étale}}^q(X, \mathcal{F}) = H_{\text{étale}}^q(X_0, \mathcal{F}|_{X_0})$ for all q and for any abelian sheaf \mathcal{F} on $X_{\text{étale}}$.*

Proof. The equivalence of categories $X_{\text{étale}} \rightarrow (X_0)_{\text{étale}}$ is given by Theorem 44.46.1. We omit the proof that under this equivalence the étale coverings correspond. Hence (1) holds. Parts (2) and (3) follow formally from (1). □

44.47. Closed immersions and pushforward

Before stating and proving Proposition 44.47.4 in its correct generality we briefly state and prove it for closed immersions. Namely, some of the preceding arguments are quite a bit easier to follow in the case of a closed immersion and so we repeat them here in their simplified form.

In the rest of this section $i : Z \rightarrow X$ is a closed immersion. The functor

$$Sch/X \longrightarrow Sch/Z, \quad U \longmapsto U_Z = Z \times_X U$$

will be denoted $U \mapsto U_Z$ as indicated. Since being a closed immersion is preserved under arbitrary base change the scheme U_Z is a closed subscheme of U .

Lemma 44.47.1. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. Let U, U' be schemes étale over X . Let $h : U_Z \rightarrow U'_Z$ be a morphism over Z . Then there exists a diagram*

$$U \xleftarrow{a} W \xrightarrow{b} U'$$

such that $a_Z : W_Z \rightarrow U_Z$ is an isomorphism and $h = b_Z \circ (a_Z)^{-1}$.

Proof. Consider the scheme $M = U \times_Y U'$. The graph $\Gamma_h \subset M_Z$ of h is open. This is true for example as Γ_h is the image of a section of the étale morphism $\text{pr}_{1,Z} : M_Z \rightarrow U_Z$, see Étale Morphisms, Proposition 40.6.1. Hence there exists an open subscheme $W \subset M$ whose intersection with the closed subset M_Z is Γ_h . Set $a = \text{pr}_1|_W$ and $b = \text{pr}_2|_W$. \square

Lemma 44.47.2. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. Let $V \rightarrow Z$ be an étale morphism of schemes. There exist étale morphisms $U_i \rightarrow X$ and morphisms $U_{i,Z} \rightarrow V$ such that $\{U_{i,Z} \rightarrow V\}$ is a Zariski covering of V .*

Proof. Since we only have to find a Zariski covering of V consisting of schemes of the form U_Z with U étale over X , we may Zariski localize on X and V . Hence we may assume X and V affine. In the affine case this is Algebra, Lemma 10.138.11. \square

If $\bar{x} : \text{Spec}(k) \rightarrow X$ is a geometric point of X , then either \bar{x} factors (uniquely) through the closed subscheme Z , or $Z_{\bar{x}} = \emptyset$. If \bar{x} factors through Z we say that \bar{x} is a geometric point of Z (because it is) and we use the notation “ $\bar{x} \in Z$ ” to indicate this.

Lemma 44.47.3. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. Let \mathcal{G} be a sheaf of sets on $Z_{\text{étale}}$. Let \bar{x} be a geometric point of X . Then*

$$(i_{\text{small},*}\mathcal{G})_{\bar{x}} = \begin{cases} * & \text{if } \bar{x} \notin Z \\ \mathcal{F}_{\bar{x}} & \text{if } \bar{x} \in Z \end{cases}$$

where $*$ denotes a singleton set.

Proof. Note that $i_{\text{small},*}\mathcal{G}|_{U_{\text{étale}}} = *$ is the final object in the category of étale sheaves on U , i.e., the sheaf which associates a singleton set to each scheme étale over U . This explains the value of $(i_{\text{small},*}\mathcal{G})_{\bar{x}}$ if $\bar{x} \notin Z$.

Next, suppose that $\bar{x} \in Z$. Note that

$$(i_{\text{small},*}\mathcal{G})_{\bar{x}} = \text{colim}_{(U,\bar{u})} \mathcal{G}(U_Z)$$

and on the other hand

$$\mathcal{G}_{\bar{x}} = \text{colim}_{(V,\bar{v})} \mathcal{G}(V).$$

Let $\mathcal{C}_1 = \{(U, \bar{u})\}^{opp}$ be the opposite of the category of étale neighbourhoods of \bar{x} in X , and let $\mathcal{C}_2 = \{(V, \bar{v})\}^{opp}$ be the opposite of the category of étale neighbourhoods of \bar{x} in Z . The canonical map

$$\mathcal{G}_{\bar{x}} \longrightarrow (i_{small,*}\mathcal{G})_{\bar{x}}$$

corresponds to the functor $F : \mathcal{C}_1 \rightarrow \mathcal{C}_2$, $F(U, \bar{u}) = (U_Z, \bar{x})$. Now Lemmas 44.47.2 and 44.47.1 imply that \mathcal{C}_1 is cofinal in \mathcal{C}_2 , see Categories, Definition 4.17.1. Hence it follows that the displayed arrow is an isomorphism, see Categories, Lemma 4.17.2. \square

Proposition 44.47.4. *Let $i : Z \rightarrow X$ be a closed immersion of schemes.*

(1) *The functor*

$$i_{small,*} : Sh(Z_{\acute{e}tale}) \longrightarrow Sh(X_{\acute{e}tale})$$

is fully faithful and its essential image is those sheaves of sets \mathcal{F} on $X_{\acute{e}tale}$ whose restriction to $X \setminus Z$ is isomorphic to $$, and*

(2) *the functor*

$$i_{small,*} : Ab(Z_{\acute{e}tale}) \longrightarrow Ab(X_{\acute{e}tale})$$

is fully faithful and its essential image is those abelian sheaves on $X_{\acute{e}tale}$ whose support is contained in Z .

In both cases i_{small}^{-1} is a left inverse to the functor $i_{small,}$.*

Proof. Let's discuss the case of sheaves of sets. For any sheaf \mathcal{G} on Z the morphism $i_{small}^{-1}i_{small,*}\mathcal{G} \rightarrow \mathcal{G}$ is an isomorphism by Lemma 44.47.3 (and Theorem 44.29.10). This implies formally that $i_{small,*}$ is fully faithful, see Sites, Lemma 7.40.1. It is clear that $i_{small,*}\mathcal{G}|_{U_{\acute{e}tale}} \cong *$ where $U = X \setminus Z$. Conversely, suppose that \mathcal{F} is a sheaf of sets on X such that $\mathcal{F}|_{U_{\acute{e}tale}} \cong *$. Consider the adjunction mapping

$$\mathcal{F} \longrightarrow i_{small,*}i_{small}^{-1}\mathcal{F}$$

Combining Lemmas 44.47.3 and 44.36.2 we see that it is an isomorphism. This finishes the proof of (1). The proof of (2) is identical. \square

44.48. Integral universally injective morphisms

Here is the general version of Proposition 44.47.4.

Proposition 44.48.1. *Let $f : X \rightarrow Y$ be a morphism of schemes which is integral and universally injective.*

(1) *The functor*

$$f_{small,*} : Sh(X_{\acute{e}tale}) \longrightarrow Sh(Y_{\acute{e}tale})$$

is fully faithful and its essential image is those sheaves of sets \mathcal{F} on $Y_{\acute{e}tale}$ whose restriction to $Y \setminus f(X)$ is isomorphic to $$, and*

(2) *the functor*

$$f_{small,*} : Ab(X_{\acute{e}tale}) \longrightarrow Ab(Y_{\acute{e}tale})$$

is fully faithful and its essential image is those abelian sheaves on $Y_{\acute{e}tale}$ whose support is contained in $f(X)$.

In both cases f_{small}^{-1} is a left inverse to the functor $f_{small,}$.*

Proof. We may factor f as

$$X \xrightarrow{h} Z \xrightarrow{i} Y$$

where h is integral, universally injective and surjective and $i : Z \rightarrow Y$ is a closed immersion. Apply Proposition 44.47.4 to i and apply Theorem 44.46.1 to h . \square

44.49. Big sites and pushforward

In this section we prove some technical results on $f_{big,*}$ for certain types of morphisms of schemes.

Lemma 44.49.1. *Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$. Let $f : X \rightarrow Y$ be a monomorphism of schemes. Then the canonical map $f_{big}^{-1} f_{big,*} \mathcal{F} \rightarrow \mathcal{F}$ is an isomorphism for any sheaf \mathcal{F} on $(\text{Sch}/X)_\tau$.*

Proof. In this case the functor $(\text{Sch}/X)_\tau \rightarrow (\text{Sch}/Y)_\tau$ is continuous, cocontinuous and fully faithful. Hence the result follows from Sites, Lemma 7.20.7. \square

Remark 44.49.2. In the situation of Lemma 44.49.1 it is true that the canonical map $\mathcal{F} \rightarrow f_{big}^{-1} f_{big!} \mathcal{F}$ is an isomorphism for any sheaf of sets \mathcal{F} on $(\text{Sch}/X)_\tau$. The proof is the same. This also holds for sheaves of abelian groups. However, note that the functor $f_{big!}$ for sheaves of abelian groups is defined in Modules on Sites, Section 18.16 and is in general different from $f_{big!}$ on sheaves of sets. The result for sheaves of abelian groups follows from Modules on Sites, Lemma 18.16.4.

Lemma 44.49.3. *Let $f : X \rightarrow Y$ be a closed immersion of schemes. Let $U \rightarrow X$ be a syntomic (resp. smooth, resp. étale) morphism. Then there exist syntomic (resp. smooth, resp. étale) morphisms $V_i \rightarrow Y$ and morphisms $V_i \times_Y X \rightarrow U$ such that $\{V_i \times_Y X \rightarrow U\}$ is a Zariski covering of U .*

Proof. Let us prove the lemma when $\tau = \text{syntomic}$. The question is local on U . Thus we may assume that U is an affine scheme mapping into an affine of Y . Hence we reduce to proving the following case: $Y = \text{Spec}(A)$, $X = \text{Spec}(A/I)$, and $U = \text{Spec}(\overline{B})$, where $A/I \rightarrow \overline{B}$ be a syntomic ring map. By Algebra, Lemma 10.131.18 we can find elements $\overline{g}_i \in \overline{B}$ such that $\overline{B}_{\overline{g}_i} = A_i/IA_i$ for certain syntomic ring maps $A \rightarrow A_i$. This proves the lemma in the syntomic case. The proof of the smooth case is the same except it uses Algebra, Lemma 10.132.19. In the étale case use Algebra, Lemma 10.138.11. \square

Lemma 44.49.4. *Let $f : X \rightarrow Y$ be a closed immersion of schemes. Let $\{U_i \rightarrow X\}$ be a syntomic (resp. smooth, resp. étale) covering. There exists a syntomic (resp. smooth, resp. étale) covering $\{V_j \rightarrow Y\}$ such that for each j , either $V_j \times_Y X = \emptyset$, or the morphism $V_j \times_Y X \rightarrow X$ factors through U_i for some i .*

Proof. For each i we can choose syntomic (resp. smooth, resp. étale) morphisms $g_{ij} : V_{ij} \rightarrow Y$ and morphisms $V_{ij} \times_Y X \rightarrow U_i$ over X , such that $\{V_{ij} \times_Y X \rightarrow U_i\}$ are Zariski coverings, see Lemma 44.49.3. This in particular implies that $\bigcup_{ij} g_{ij}(V_{ij})$ contains the closed subset $f(X)$. Hence the family of syntomic (resp. smooth, resp. étale) maps g_{ij} together with the open immersion $Y \setminus f(X) \rightarrow Y$ forms the desired syntomic (resp. smooth, resp. étale) covering of Y . \square

Lemma 44.49.5. *Let $f : X \rightarrow Y$ be a closed immersion of schemes. Let $\tau \in \{\text{syntomic, smooth, étale}\}$. The functor $V \mapsto X \times_Y V$ defines an almost cocontinuous functor (see Sites, Definition 7.41.3) $(\text{Sch}/Y)_\tau \rightarrow (\text{Sch}/X)_\tau$ between big τ sites.*

Proof. We have to show the following: given a morphism $V \rightarrow Y$ and any syntomic (resp. smooth, resp. étale) covering $\{U_i \rightarrow X \times_Y V\}$, there exists a smooth (resp. smooth, resp. étale) covering $\{V_j \rightarrow V\}$ such that for each j , either $X \times_Y V_j$ is empty, or $X \times_Y V_j \rightarrow Z \times_Y V$ factors through one of the U_i . This follows on applying Lemma 44.49.4 above to the closed immersion $X \times_Y V \rightarrow V$. \square

Lemma 44.49.6. *Let $f : X \rightarrow Y$ be a closed immersion of schemes. Let $\tau \in \{\text{syntomic, smooth, étale}\}$.*

- (1) *The pushforward $f_{\text{big},*} : \text{Sh}((\text{Sch}/X)_\tau) \rightarrow \text{Sh}((\text{Sch}/Y)_\tau)$ commutes with coequalizers and pushouts.*
- (2) *The pushforward $f_{\text{big},*} : \text{Ab}((\text{Sch}/X)_\tau) \rightarrow \text{Ab}((\text{Sch}/Y)_\tau)$ is exact.*

Proof. This follows from Sites, Lemma 7.41.6, Modules on Sites, Lemma 18.15.3, and Lemma 44.49.5 above. \square

Remark 44.49.7. In Lemma 44.49.6 the case $\tau = \text{fppf}$ is missing. The reason is that given a ring A , an ideal I and a faithfully flat, finitely presented ring map $A/I \rightarrow \overline{B}$, there is no reason to think that one can find *any* flat finitely presented ring map $A \rightarrow B$ with $B/IB \neq 0$ such that $A/I \rightarrow B/IB$ factors through \overline{B} . Hence the proof of Lemma 44.49.5 does not work for the fppf topology. In fact it is likely false that $f_{\text{big},*} : \text{Ab}((\text{Sch}/X)_{\text{fppf}}) \rightarrow \text{Ab}((\text{Sch}/Y)_{\text{fppf}})$ is exact when f is a closed immersion. If you know an example, please email stacks.project@gmail.com.

44.50. Exactness of big lower shriek

This is just the following technical result. Note that the functor $f_{\text{big}!}$ has nothing whatsoever to do with cohomology with compact support in general.

Lemma 44.50.1. *Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$. Let $f : X \rightarrow Y$ be a morphism of schemes. Let*

$$f_{\text{big}} : \text{Sh}((\text{Sch}/X)_\tau) \longrightarrow \text{Sh}((\text{Sch}/Y)_\tau)$$

be the corresponding morphism of topoi as in Topologies, Lemma 33.3.15, 33.4.15, 33.5.10, 33.6.10, or 33.7.12.

- (1) *The functor $f_{\text{big}}^{-1} : \text{Ab}((\text{Sch}/Y)_\tau) \rightarrow \text{Ab}((\text{Sch}/X)_\tau)$ has a left adjoint*

$$f_{\text{big}!} : \text{Ab}((\text{Sch}/X)_\tau) \rightarrow \text{Ab}((\text{Sch}/Y)_\tau)$$

which is exact.

- (2) *The functor $f_{\text{big}}^* : \text{Mod}((\text{Sch}/Y)_\tau, \mathcal{O}) \rightarrow \text{Mod}((\text{Sch}/X)_\tau, \mathcal{O})$ has a left adjoint*

$$f_{\text{big}!} : \text{Mod}((\text{Sch}/X)_\tau, \mathcal{O}) \rightarrow \text{Mod}((\text{Sch}/Y)_\tau, \mathcal{O})$$

which is exact.

Moreover, the two functors $f_{\text{big}!}$ agree on underlying sheaves of abelian groups.

Proof. Recall that f_{big} is the morphism of topoi associated to the continuous and cocontinuous functor $u : (Sch/X)_\tau \rightarrow (Sch/Y)_\tau, U/X \mapsto U/Y$. Moreover, we have $f_{big}^{-1}\mathcal{O} = \mathcal{O}$. Hence the existence of $f_{big!}$ follows from Modules on Sites, Lemma 18.16.2, respectively Modules on Sites, Lemma 18.40.1. Note that if U is an object of $(Sch/X)_\tau$ then the functor u induces an equivalence of categories

$$u' : (Sch/X)_\tau/U \longrightarrow (Sch/Y)_\tau/U$$

because both sides of the arrow are equal to $(Sch/U)_\tau$. Hence the agreement of $f_{big!}$ on underlying abelian sheaves follows from the discussion in Modules on Sites, Remark 18.40.2. The exactness of $f_{big!}$ follows from Modules on Sites, Lemma 18.16.3 as the functor u above which commutes with fibre products and equalizers. \square

Next, we prove a technical lemma that will be useful later when comparing sheaves of modules on different sites associated to algebraic stacks.

Lemma 44.50.2. *Let X be a scheme. Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$. Let $\mathcal{C}_1 \subset \mathcal{C}_2 \subset (Sch/X)_\tau$ be full subcategories with the following properties:*

- (1) *For an object U/X of \mathcal{C}_t ,*
 - (a) *if $\{U_i \rightarrow U\}$ is a covering of $(Sch/X)_\tau$, then U_i/X is an object of \mathcal{C}_t ,*
 - (b) *$U \times \mathbf{A}^1/X$ is an object of \mathcal{C}_t .*
- (2) *X/X is an object of \mathcal{C}_t .*

We endow \mathcal{C}_t with the structure of a site whose coverings are exactly those coverings $\{U_i \rightarrow U\}$ of $(Sch/X)_\tau$ with $U \in \text{Ob}(\mathcal{C}_t)$. Then

- (i) *The functor $\mathcal{C}_1 \rightarrow \mathcal{C}_2$ is fully faithful, continuous, and cocontinuous.*

Denote $g : Sh(\mathcal{C}_1) \rightarrow Sh(\mathcal{C}_2)$ the corresponding morphism of topoi. Denote \mathcal{O}_t the restriction of \mathcal{O} to \mathcal{C}_t . Denote $g_!$ the functor of Modules on Sites, Definition 18.16.1.

- (ii) *The canonical map $g_!\mathcal{O}_1 \rightarrow \mathcal{O}_2$ is an isomorphism.*

Proof. Assertion (i) is immediate from the definitions. In this proof all schemes are schemes over X and all morphisms of schemes are morphisms of schemes over X . Note that g^{-1} is given by restriction, so that for an object U of \mathcal{C}_1 we have $\mathcal{O}_1(U) = \mathcal{O}_2(U) = \mathcal{O}(U)$. Recall that $g_!\mathcal{O}_1$ is the sheaf associated to the presheaf $g_{p!}\mathcal{O}_1$ which associates to V in \mathcal{C}_2 the group

$$\text{colim}_{V \rightarrow U} \mathcal{O}(U)$$

where U runs over the objects of \mathcal{C}_1 and the colimit is taken in the category of abelian groups. Below we will use frequently that if

$$V \rightarrow U \rightarrow U'$$

are morphisms with $U, U' \in \text{Ob}(\mathcal{C}_1)$ and if $f' \in \mathcal{O}(U')$ restricts to $f \in \mathcal{O}(U)$, then $(V \rightarrow U, f)$ and $(V \rightarrow U', f')$ define the same element of the colimit. Also, $g_!\mathcal{O}_1 \rightarrow \mathcal{O}_2$ maps the element $(V \rightarrow U, f)$ simply to the pullback of f to V .

Surjectivity. Let V be a scheme and let $h \in \mathcal{O}(V)$. Then we obtain a morphism $V \rightarrow X \times \mathbf{A}^1$ induced by h and the structure morphism $V \rightarrow X$. Writing $\mathbf{A}^1 = \text{Spec}(\mathbf{Z}[x])$ we see the element $x \in \mathcal{O}(X \times \mathbf{A}^1)$ pulls back to h . Since $X \times \mathbf{A}^1$ is an object of \mathcal{C}_1 by assumptions (1)(b) and (2) we obtain the desired surjectivity.

Injectivity. Let V be a scheme. Let $s = \sum_{i=1, \dots, n} (V \rightarrow U_i, f_i)$ be an element of the colimit displayed above. For any i we can use the morphism $f_i : U_i \rightarrow X \times \mathbf{A}^1$ to see

that $(V \rightarrow U_i, f_i)$ defines the same element of the colimit as $(f_i : V \rightarrow X \times \mathbf{A}^1, x)$. Then we can consider

$$f_1 \times \dots \times f_n : V \rightarrow X \times \mathbf{A}^n$$

and we see that s is equivalent in the colimit to

$$\sum_{i=1, \dots, n} (f_1 \times \dots \times f_n : V \rightarrow X \times \mathbf{A}^n, x_i) = (f_1 \times \dots \times f_n : V \rightarrow X \times \mathbf{A}^n, x_1 + \dots + x_n)$$

Now, if $x_1 + \dots + x_n$ restricts to zero on V , then we see that $f_1 \times \dots \times f_n$ factors through $X \times \mathbf{A}^{n-1} = V(x_1 + \dots + x_n)$. Hence we see that s is equivalent to zero in the colimit. \square

44.51. Étale cohomology

In the following sections we prove some basic results on étale cohomology. Here is an example of something we know for cohomology of topological spaces which also holds for étale cohomology.

Lemma 44.51.1 (Mayer-Vietoris for étale cohomology). *Let X be a scheme. Suppose that $X = U \cup V$ is a union of two opens. For any abelian sheaf \mathcal{F} on $X_{\text{étale}}$ there exists a long exact cohomology sequence*

$$\begin{aligned} 0 \rightarrow H_{\text{étale}}^0(X, \mathcal{F}) \rightarrow H_{\text{étale}}^0(U, \mathcal{F}) \oplus H_{\text{étale}}^0(V, \mathcal{F}) \rightarrow H_{\text{étale}}^0(U \cap V, \mathcal{F}) \\ \rightarrow H_{\text{étale}}^1(X, \mathcal{F}) \rightarrow H_{\text{étale}}^1(U, \mathcal{F}) \oplus H_{\text{étale}}^1(V, \mathcal{F}) \rightarrow H_{\text{étale}}^1(U \cap V, \mathcal{F}) \end{aligned}$$

This long exact sequence is functorial in \mathcal{F} .

Proof. Observe that if \mathcal{I} is an injective abelian sheaf, then

$$0 \rightarrow \mathcal{I}(X) \rightarrow \mathcal{I}(U) \oplus \mathcal{I}(V) \rightarrow \mathcal{I}(U \cap V) \rightarrow 0$$

is exact. This is true in the first and middle spots as \mathcal{I} is a sheaf. It is true on the right, because $\mathcal{I}(U) \rightarrow \mathcal{I}(U \cap V)$ is surjective by Cohomology on Sites, Lemma 21.12.6. Another way to prove it would be to show that the cokernel of the map $\mathcal{I}(U) \oplus \mathcal{I}(V) \rightarrow \mathcal{I}(U \cap V)$ is the first Čech cohomology group of \mathcal{I} with respect to the covering $X = U \cup V$ which vanishes by Lemmas 44.18.7 and 44.19.1. Thus, if $\mathcal{F} \rightarrow \mathcal{I}^\bullet$ is an injective resolution, then

$$0 \rightarrow \mathcal{I}^\bullet(X) \rightarrow \mathcal{I}^\bullet(U) \oplus \mathcal{I}^\bullet(V) \rightarrow \mathcal{I}^\bullet(U \cap V) \rightarrow 0$$

is a short exact sequence of complexes and the associated long exact cohomology sequence is the sequence of the statement of the lemma. \square

44.52. Colimits

We recall that if $(\mathcal{F}_i, \varphi_{ii'})$ is a diagram of sheaves on a site \mathcal{C} its colimit (in the category of sheaves) is the sheafification of the presheaf $U \mapsto \text{colim}_i \mathcal{F}_i(U)$. See Sites, Lemma 7.10.13. If the system is directed, U is a quasi-compact object of \mathcal{C} which has a cofinal system of coverings by quasi-compact objects, then $\mathcal{F}(U) = \text{colim}_i \mathcal{F}_i(U)$, see Sites, Lemma 7.11.2. See Cohomology on Sites, Lemma 21.16.1 for a result dealing with higher cohomology groups of colimits of abelian sheaves.

We first state and prove a very general result on colimits and cohomology and then we explain what it means in some special cases.

Theorem 44.52.1. *Let $X = \lim_{i \in I} X_i$ be a limit of a directed system of schemes with affine transition morphisms $f_{i'i} : X_{i'} \rightarrow X_i$. We assume that X_i is quasi-compact and quasi-separated for all $i \in I$. Assume given*

(1) an abelian sheaf \mathcal{F}_i on $(X_i)_{\acute{e}tale}$ for all $i \in I$,
 (2) for $i' \geq i$ a map $\varphi_{i'i} : f_{i'}^{-1}\mathcal{F}_i \rightarrow \mathcal{F}_{i'}$ of abelian sheaves on $(X_{i'})_{\acute{e}tale}$
 such that $\varphi_{i''i} = \varphi_{i''i'} \circ f_{i''i'}^{-1}\varphi_{i'i}$ whenever $i'' \geq i' \geq i$. Denote $f_i : X \rightarrow X_i$ the projection and set $\mathcal{F} = \text{colim } f_i^{-1}\mathcal{F}_i$. Then

$$\text{colim}_{i \in I} H_{\acute{e}tale}^p(X_i, \mathcal{F}_i) = H_{\acute{e}tale}^p(X, \mathcal{F}).$$

for all $p \geq 0$.

Proof. Let us use the affine étale sites of X and X_i as introduced in Lemma 44.21.2. We claim that

$$X_{\text{affine}, \acute{e}tale} = \text{colim}(X_i)_{\text{affine}, \acute{e}tale}$$

as sites (see Sites, Lemma 7.11.6). If we prove this, then the theorem follows from Cohomology on Sites, Lemma 21.16.2. The category of schemes of finite presentation over X is the colimit of the categories of schemes of finite presentation over X_i , see Limits, Lemma 31.9.1. The same holds for the subcategories of affine objects étale over X by Limits, Lemmas 31.3.10 and 31.7.8. Finally, if $\{U^j \rightarrow U\}$ is a covering of $X_{\text{affine}, \acute{e}tale}$ and if $U_i^j \rightarrow U_i$ is morphism of affine schemes étale over X_i whose base change to X is $U^j \rightarrow U$, then we see that the base change of $\{U_i^j \rightarrow U_i\}$ to some $X_{i'}$ is a covering for i' large enough, see Limits, Lemma 31.7.11. □

The following two results are special cases of the theorem above.

Lemma 44.52.2. *Let X be a quasi-compact and quasi-separated scheme. Let $(\mathcal{F}_i, \varphi_{ij})$ be a system of abelian sheaves on $X_{\acute{e}tale}$ over the partially ordered set I . If I is directed then*

$$\text{colim}_{i \in I} H_{\acute{e}tale}^p(X, \mathcal{F}_i) = H_{\acute{e}tale}^p(X, \text{colim}_{i \in I} \mathcal{F}_i).$$

Proof. This is a special case of Theorem 44.52.1. We also sketch a direct proof. We prove it for all X at the same time, by induction on p .

- (1) For any quasi-compact and quasi-separated scheme X and any étale covering \mathcal{U} of X , show that there exists a refinement $\mathcal{V} = \{V_j \rightarrow X\}_{j \in J}$ with J finite and each V_j quasi-compact and quasi-separated such that all $V_{j_0} \times_X \dots \times_X V_{j_p}$ are also quasi-compact and quasi-separated.
- (2) Using the previous step and the definition of colimits in the category of sheaves, show that the theorem holds for $p = 0$ and all X .
- (3) Using the locality of cohomology (Lemma 44.22.3), the Čech-to-cohomology spectral sequence (Theorem 44.19.2) and the fact that the induction hypothesis applies to all $V_{j_0} \times_X \dots \times_X V_{j_p}$ in the above situation, prove the induction step $p \rightarrow p + 1$. □

Lemma 44.52.3. *Let A be a ring, (I, \leq) a directed poset and (B_i, φ_{ij}) a system of A -algebras. Set $B = \text{colim}_{i \in I} B_i$. Let $X \rightarrow \text{Spec}(A)$ be a quasi-compact and quasi-separated morphism of schemes. Let \mathcal{F} an abelian sheaf on $X_{\acute{e}tale}$. Denote $Y_i = X \times_{\text{Spec}(A)} \text{Spec}(B_i)$, $Y = X \times_{\text{Spec}(A)} \text{Spec}(B)$, $\mathcal{G}_i = (Y_i \rightarrow X)^{-1}\mathcal{F}$ and $\mathcal{G} = (Y \rightarrow X)^{-1}\mathcal{F}$. Then*

$$H_{\acute{e}tale}^p(Y, \mathcal{G}) = \text{colim}_{i \in I} H_{\acute{e}tale}^p(X_i, \mathcal{G}_i).$$

Proof. This is a special case of Theorem 44.52.1. We also outline a direct proof as follows.

- (1) Given $V \rightarrow Y$ étale with V quasi-compact and quasi-separated, there exist $i \in I$ and $V_i \rightarrow Y_i$ such that $V = V_i \times_{Y_i} Y$. If all the schemes considered were affine, this would correspond to the following algebra statement: if $B = \operatorname{colim} B_i$ and $B \rightarrow C$ is étale, then there exist $i \in I$ and $B_i \rightarrow C_i$ étale such that $C \cong B \otimes_{B_i} C_i$. This is proved in Algebra, Lemma 10.138.3.
- (2) In the situation of (1) show that $\mathcal{G}(V) = \operatorname{colim}_{i' \geq i} \mathcal{G}_{i'}(V_{i'})$ where $V_{i'}$ is the base change of V_i to $Y_{i'}$.
- (3) By (1), we see that for every étale covering $\mathcal{V} = \{V_j \rightarrow Y\}_{j \in J}$ with J finite and the V_j s quasi-compact and quasi-separated, there exists $i \in I$ and an étale covering $\mathcal{V}_i = \{V_{ij} \rightarrow Y_i\}_{j \in J}$ such that $\mathcal{V} \cong \mathcal{V}_i \times_{Y_i} Y$.
- (4) Show that (2) and (3) imply

$$\check{H}^*(\mathcal{V}, \mathcal{G}) = \operatorname{colim}_{i \in I} \check{H}^*(\mathcal{V}_i, \mathcal{G}_i).$$

- (5) Cleverly use the Čech-to-cohomology spectral sequence (Theorem 44.19.2). □

Lemma 44.52.4. *Let $f : X \rightarrow Y$ be a morphism of schemes and $\mathcal{F} \in \operatorname{Ab}(X_{\text{étale}})$. Then $R^p f_* \mathcal{F}$ is the sheaf associated to the presheaf*

$$(V \rightarrow Y) \mapsto H_{\text{étale}}^p(X \times_Y V, \mathcal{F}|_{X \times_Y V}).$$

Proof. This lemma is valid for topological spaces, and the proof in this case is the same. See Cohomology on Sites, Lemma 21.8.4 for details. □

Lemma 44.52.5. *Let S be a scheme. Let $X = \lim_{i \in I} X_i$ be a limit of a directed system of schemes over S with affine transition morphisms $f_{i'} : X_{i'} \rightarrow X_i$. We assume the structure morphism $g_i : X_i \rightarrow S$ is quasi-compact and quasi-separated for all $i \in I$ and we set $g : X \rightarrow S$. Assume given*

- (1) *an abelian sheaf \mathcal{F}_i on $(X_i)_{\text{étale}}$ for all $i \in I$,*
- (2) *for $i' \geq i$ a map $\varphi_{i'} : f_{i'}^{-1} \mathcal{F}_i \rightarrow \mathcal{F}_{i'}$ of abelian sheaves on $(X_{i'})_{\text{étale}}$*

such that $\varphi_{i''} = \varphi_{i''i'} \circ f_{i''i'}^{-1} \varphi_{i'}$ whenever $i'' \geq i' \geq i$. Denote $f_i : X \rightarrow X_i$ the projection and set $\mathcal{F} = \operatorname{colim} f_i^{-1} \mathcal{F}_i$. Then

$$\operatorname{colim}_{i \in I} R^p g_{i,*} \mathcal{F}_i = R^p g_* \mathcal{F}$$

for all $p \geq 0$.

Proof. Recall (Lemma 44.52.4) that $R^p g_{i,*} \mathcal{F}_i$ is the sheaf associated to the presheaf $U \mapsto H_{\text{étale}}^p(U \times_S X_i, \mathcal{F}_i)$ and similarly for $R^p g_* \mathcal{F}$. Moreover, the colimit of a system of sheaves is the sheafification of the colimit on the level of presheaves. Note that every object of $S_{\text{étale}}$ has a covering by quasi-compact and quasi-separated objects (e.g., affine schemes). Moreover, if U is a quasi-compact and quasi-separated object, then we have

$$\operatorname{colim} H_{\text{étale}}^p(U \times_S X_i, \mathcal{F}_i) = H_{\text{étale}}^p(U \times_S X, \mathcal{F})$$

by Theorem 44.52.1. Thus the lemma follows. □

44.53. Stalks of higher direct images

Theorem 44.53.1. *Let $f : X \rightarrow S$ be a quasi-compact and quasi-separated morphism of schemes, \mathcal{F} an abelian sheaf on $X_{\text{étale}}$, and \bar{s} a geometric point of S . Then*

$$(R^p f_* \mathcal{F})_{\bar{s}} = H_{\text{étale}}^p(X \times_S \text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh}), p^{-1} \mathcal{F})$$

where $p : X \times_S \text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh}) \rightarrow X$ is the projection.

Proof. Let \mathcal{I} be the category of étale neighborhoods of \bar{s} on S . By Lemma 44.52.4 we have

$$(R^p f_* \mathcal{F})_{\bar{s}} = \text{colim}_{(V, \bar{v}) \in \mathcal{I}^{opp}} H^p(X \times_S V, \mathcal{F}|_{X \times_S V}).$$

We may replace \mathcal{I} by the initial subcategory consisting of affine étale neighbourhoods of \bar{s} . Observe that

$$\text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh}) = \lim_{(V, \bar{v}) \in \mathcal{I}} V$$

by Lemma 44.33.1 and Limits, Lemma 31.2.1. Since fibre products commute with limits we also obtain

$$X \times_S \text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh}) = \lim_{(V, \bar{v}) \in \mathcal{I}} X \times_S V$$

We conclude by Lemma 44.52.3. □

44.54. The Leray spectral sequence

Lemma 44.54.1. *Let $f : X \rightarrow Y$ be a morphism and \mathcal{I} an injective object of $Ab(X_{\text{étale}})$. Let $V \in \text{Ob}(Y_{\text{étale}})$. Then*

- (1) *for any covering $\mathcal{V} = \{V_j \rightarrow V\}_{j \in J}$ we have $\check{H}^p(\mathcal{V}, f_* \mathcal{I}) = 0$ for all $p > 0$,*
- (2) *$f_* \mathcal{I}$ is acyclic for the functor $\Gamma(V, -)$, and*
- (3) *if $g : Y \rightarrow Z$, then $f_* \mathcal{I}$ is acyclic for g_* .*

Proof. Observe that $\check{C}^\bullet(\mathcal{V}, f_* \mathcal{I}) = \check{C}^\bullet(\mathcal{V} \times_Y X, \mathcal{I})$ which has vanishing higher cohomology groups by Lemma 44.18.7. This proves (1). The second statement follows as a sheaf which has vanishing higher Čech cohomology groups for any covering has vanishing higher cohomology groups. This a wonderful exercise in using the Čech-to-cohomology spectral sequence, but see Cohomology on Sites, Lemma 21.11.9 for details and a more precise and general statement. Part (3) is a consequence of (2) and the description of $R^p g_*$ in Lemma 44.52.4. □

Using the formalism of Grothendieck spectral sequences, this gives the following.

Proposition 44.54.2 (Leray spectral sequence). *Let $f : X \rightarrow Y$ be a morphism of schemes and \mathcal{F} an étale sheaf on X . Then there is a spectral sequence*

$$E_2^{p, q} = H_{\text{étale}}^p(Y, R^q f_* \mathcal{F}) \Rightarrow H_{\text{étale}}^{p+q}(X, \mathcal{F}).$$

Proof. See Lemma 44.54.1 and see Derived Categories, Section 13.22. □

44.55. Vanishing of finite higher direct images

The next goal is to prove that the higher direct images of a finite morphism of schemes vanish.

Lemma 44.55.1. *Let R be a strictly henselian local ring. Set $S = \text{Spec}(R)$ and let \bar{s} be its closed point. Then the global sections functor $\Gamma(S, -) : \text{Ab}(S_{\text{étale}}) \rightarrow \text{Ab}$ is exact. In fact we have $\Gamma(S, \mathcal{F}) = \mathcal{F}_{\bar{s}}$ for any sheaf of sets \mathcal{F} . In particular*

$$\forall p \geq 1, \quad H_{\text{étale}}^p(S, \mathcal{F}) = 0$$

for all $\mathcal{F} \in \text{Ab}(S_{\text{étale}})$.

Proof. If we show that $\Gamma(S, \mathcal{F}) = \mathcal{F}_{\bar{s}}$ the $\Gamma(S, -)$ is exact as the stalk functor is exact. Let (U, \bar{u}) be an étale neighbourhood of \bar{s} . Pick an affine open neighborhood $\text{Spec}(A)$ of \bar{u} in U . Then $R \rightarrow A$ is étale and $\kappa(\bar{s}) = \kappa(\bar{u})$. By Theorem 44.32.4 we see that $A \cong R \times A'$ as an R -algebra compatible with maps to $\kappa(\bar{s}) = \kappa(\bar{u})$. Hence we get a section

$$\begin{array}{ccc} \text{Spec}(A) & \longrightarrow & U \\ & \searrow & \downarrow \\ & & S \end{array}$$

It follows that in the system of étale neighbourhoods of \bar{s} the identity map $(S, \bar{s}) \rightarrow (S, \bar{s})$ is cofinal. Hence $\Gamma(S, \mathcal{F}) = \mathcal{F}_{\bar{s}}$. The final statement of the lemma follows as the higher derived functors of an exact functor are zero, see Derived Categories, Lemma 13.17.8. \square

Proposition 44.55.2. *Let $f : X \rightarrow Y$ be a finite morphism of schemes.*

(1) *For any geometric point $\bar{y} : \text{Spec}(k) \rightarrow Y$ we have*

$$(f_* \mathcal{F})_{\bar{y}} = \prod_{\bar{x} : \text{Spec}(k) \rightarrow X, f(\bar{x}) = \bar{y}} \mathcal{F}_{\bar{x}}$$

for \mathcal{F} in $\text{Sh}(X_{\text{étale}})$ and

$$(f_* \mathcal{F})_{\bar{y}} = \bigoplus_{\bar{x} : \text{Spec}(k) \rightarrow X, f(\bar{x}) = \bar{y}} \mathcal{F}_{\bar{x}}$$

for \mathcal{F} in $\text{Ab}(X_{\text{étale}})$.

(2) *For any $q \geq 1$ we have $R^q f_* \mathcal{F} = 0$.*

Proof. Let $X_{\bar{y}}^{\text{sh}}$ denote the fiber product $X \times_Y \text{Spec}(\mathcal{O}_{Y, \bar{y}}^{\text{sh}})$. By Theorem 44.53.1 the stalk of $R^q f_* \mathcal{F}$ at \bar{y} is computed by $H_{\text{étale}}^q(X_{\bar{y}}^{\text{sh}}, \mathcal{F})$. Since f is finite, $X_{\bar{y}}^{\text{sh}}$ is finite over $\text{Spec}(\mathcal{O}_{Y, \bar{y}}^{\text{sh}})$, thus $X_{\bar{y}}^{\text{sh}} = \text{Spec}(A)$ for some ring A finite over $\mathcal{O}_{Y, \bar{y}}^{\text{sh}}$. Since the latter is strictly henselian, Lemma 44.32.5 implies that A is a finite product of henselian local rings $A = A_1 \times \dots \times A_r$. Since the residue field of $\mathcal{O}_{Y, \bar{y}}^{\text{sh}}$ is separably closed the same is true for each A_i . Hence A_i is strictly henselian. This implies that $X_{\bar{y}}^{\text{sh}} = \prod_{i=1}^r \text{Spec}(A_i)$. The vanishing of Lemma 44.55.1 implies that $(R^q f_* \mathcal{F})_{\bar{y}} = 0$ for $q > 0$ which implies (2) by Theorem 44.29.10. Part (1) follows from the corresponding statement of Lemma 44.55.1. \square

Lemma 44.55.3. *Consider a cartesian square*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ f' \downarrow & & \downarrow f \\ Y' & \xrightarrow{g} & Y \end{array}$$

of schemes with f a finite morphism. For any sheaf of sets \mathcal{F} on $X_{\text{étale}}$ we have $f'_*(g')^{-1} \mathcal{F} = g^{-1} f_* \mathcal{F}$.

Proof. In great generality there is a pullback map $g^{-1}f_*\mathcal{F} \rightarrow f'_*(g')^{-1}\mathcal{F}$, see Sites, Section 7.44. To check this map is an isomorphism it suffices to check on stalks (Theorem 44.29.10). This is clear from the description of stalks in Proposition 44.55.2 and Lemma 44.36.2. \square

The following lemma is a case of cohomological descent dealing with étale sheaves and finite surjective morphisms. We will significantly generalize this result once we prove the proper base change theorem.

Lemma 44.55.4. *Let $f : X \rightarrow Y$ be a surjective finite morphism of schemes. Set $f_n : X_n \rightarrow Y$ equal to the $(n + 1)$ -fold fibre product of X over Y . For $\mathcal{F} \in \text{Ab}(Y_{\text{étale}})$ set $\mathcal{F}_n = f_{n,*}f_n^{-1}\mathcal{F}$. There is an exact sequence*

$$0 \rightarrow \mathcal{F} \rightarrow \mathcal{F}_0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \dots$$

on $X_{\text{étale}}$. Moreover, there is a spectral sequence

$$E_1^{p,q} = H_{\text{étale}}^q(X_p, f_p^{-1}\mathcal{F})$$

converging to $H^{p+q}(Y_{\text{étale}}, \mathcal{F})$. This spectral sequence is functorial in \mathcal{F} .

Proof. If we prove the first statement of the lemma, then we obtain a spectral sequence with $E_1^{p,q} = H_{\text{étale}}^q(Y, \mathcal{F})$ converging to $H^{p+q}(Y_{\text{étale}}, \mathcal{F})$, see Derived Categories, Lemma 13.21.3. On the other hand, since $R^i f_{p,*}f_p^{-1}\mathcal{F} = 0$ for $i > 0$ (Proposition 44.55.2) we get

$$H_{\text{étale}}^q(X_p, f_p^{-1}\mathcal{F}) = H_{\text{étale}}^q(Y, f_{p,*}f_p^{-1}\mathcal{F}) = H_{\text{étale}}^q(Y, \mathcal{F}_p)$$

by Proposition 44.54.2 and we get the spectral sequence of the lemma.

To prove the first statement of the lemma, observe that X_n forms a simplicial scheme over Y , see Simplicial, Example 14.3.5. Observe moreover, that for each of the projections $d_j : X_{n+1} \rightarrow X_n$ there is a map $d_j^{-1}f_n^{-1}\mathcal{F} \rightarrow f_{n+1}^{-1}\mathcal{F}$. These maps induce maps

$$\delta_j : \mathcal{F}_n \rightarrow \mathcal{F}_{n+1}$$

for $j = 0, \dots, n + 1$. We use the alternating sum of these maps to define the differentials $\mathcal{F}_n \rightarrow \mathcal{F}_{n+1}$. Similarly, there is a canonical augmentation $\mathcal{F} \rightarrow \mathcal{F}_0$, namely this is just the canonical map $\mathcal{F} \rightarrow f_*f^{-1}\mathcal{F}$. To check that this sequence of sheaves is an exact complex it suffices to check on stalks at geometric points (Theorem 44.29.10). Thus we let $\bar{y} : \text{Spec}(k) \rightarrow Y$ be a geometric point. Let $E = \{\bar{x} : \text{Spec}(k) \rightarrow X \mid f(\bar{x}) = \bar{y}\}$. Then E is a finite nonempty set and we see that

$$(\mathcal{F}_n)_{\bar{y}} = \bigoplus_{e \in E^{n+1}} \mathcal{F}_{\bar{y}}$$

by Proposition 44.55.2 and Lemma 44.36.2. Thus we have to see that given an abelian group M the sequence

$$0 \rightarrow M \rightarrow \bigoplus_{e \in E} M \rightarrow \bigoplus_{e \in E^2} M \rightarrow \dots$$

is exact. Here the first map is the diagonal map and the map $\bigoplus_{e \in E^{n+1}} M \rightarrow \bigoplus_{e \in E^{n+2}} M$ is the alternating sum of the maps induced by the $(n + 2)$ projections $E^{n+2} \rightarrow E^{n+1}$. This can be shown directly or deduced by applying Simplicial, Lemma 14.25.9 to the map $E \rightarrow \{*\}$. \square

Remark 44.55.5. In the situation of Lemma 44.55.4 if \mathcal{G} is a sheaf of sets on $Y_{\acute{e}tale}$, then we have

$$\Gamma(Y, \mathcal{G}) = \text{Equalizer}(\Gamma(X_0, f_0^{-1}\mathcal{G}) \rightrightarrows \Gamma(X_1, f_1^{-1}\mathcal{G}))$$

This is proved in exactly the same way, by showing that the sheaf \mathcal{G} is the equalizer of the two maps $f_{0,*}f_0^{-1}\mathcal{G} \rightarrow f_{1,*}f_1^{-1}\mathcal{G}$.

Here is a fun generalization of Lemma 44.55.1.

Lemma 44.55.6. *Let S be a scheme all of whose local rings are strictly henselian. Then for any abelian sheaf \mathcal{F} on $S_{\acute{e}tale}$ we have $H^i(S_{\acute{e}tale}, \mathcal{F}) = H^i(S_{Zar}, \mathcal{F})$.*

Proof. Let $\epsilon : S_{\acute{e}tale} \rightarrow S_{Zar}$ be the morphism of sites given by the inclusion functor. The Zariski sheaf $R^p\epsilon_*\mathcal{F}$ is the sheaf associated to the presheaf $U \mapsto H_{\acute{e}tale}^p(U, \mathcal{F})$. Thus the stalk at $x \in X$ is $\text{colim} H_{\acute{e}tale}^p(U, \mathcal{F}) = H_{\acute{e}tale}^p(\text{Spec}(\mathcal{O}_{X,x}), \mathcal{G}_x)$ where \mathcal{G}_x denotes the pullback of \mathcal{F} to $\text{Spec}(\mathcal{O}_{X,x})$, see Lemma 44.52.3. Thus the higher direct images of $R^p\epsilon_*\mathcal{F}$ are zero by Lemma 44.55.1 and we conclude by the Leray spectral sequence. \square

Lemma 44.55.7. *Let S be an affine scheme such that (1) all points are closed, and (2) all residue fields are separably algebraically closed. Then for any abelian sheaf \mathcal{F} on $S_{\acute{e}tale}$ we have $H^i(S_{\acute{e}tale}, \mathcal{F}) = 0$ for $i > 0$.*

Proof. Condition (1) implies that the underlying topological space of S is profinite, see Algebra, Lemma 10.25.5. Thus the higher cohomology groups of an abelian sheaf on the topological space S (i.e., Zariski cohomology) is trivial, see Cohomology, Lemma 20.23.3. The local rings are strictly henselian by Algebra, Lemma 10.145.11. Thus étale cohomology of S is computed by Zariski cohomology by Lemma 44.55.6 and the proof is done. \square

44.56. Schemes étale over a point

In this section we describe schemes étale over the spectrum of a field. Before we state the result we introduce the category of G -sets for a topological group G .

Definition 44.56.1. Let G be a topological group. A G -set, sometime called a *discrete G -set*, is a set X endowed with a left action $a : G \times X \rightarrow X$ such that a is continuous when X is given the discrete topology and $G \times X$ the product topology. A *morphism of G -sets* $f : X \rightarrow Y$ is simply any G -equivariant map from X to Y . The category of G -sets is denoted $G\text{-Sets}$.

The condition that $a : G \times X \rightarrow X$ is continuous signifies simply that the stabilizer of any $x \in X$ is open in G . If G is an abstract group G (i.e., a group but not a topological group) then this agrees with our preceding definition (see for example Sites, Example 7.6.5) provided we endow G with the discrete topology.

Recall that if $K \subset L$ is an infinite Galois extension the Galois group $G = \text{Gal}(L/K)$ comes endowed with a canonical topology. Namely the open subgroups are the subgroups of the form $\text{Gal}(L/K') \subset G$ where K'/K is a finite subextension of L/K . The index of an open subgroup is always finite. We say that G is a profinite (topological) group.

Lemma 44.56.2. *Let K be a field. Let K^{sep} a separable closure of K . Consider the profinite group*

$$G = \text{Aut}_{\text{Spec}(K)}(\text{Spec}(K^{sep}))^{opp} = \text{Gal}(K^{sep}/K)$$

The functor

$$\begin{array}{ccc} \text{schemes étale over } K & \longrightarrow & G\text{-Sets} \\ X/K & \longmapsto & \text{Mor}_{\text{Spec}(K)}(\text{Spec}(K^{sep}), X) \end{array}$$

is an equivalence of categories.

Proof. A scheme X over K is étale over K if and only if $X \cong \coprod_{i \in I} \text{Spec}(K_i)$ with each K_i a finite separable extension of K . The functor of the lemma associates to X the G -set

$$\coprod_i \text{Hom}_K(K_i, K^{sep})$$

with its natural left G -action. Each element has an open stabilizer by definition of the topology on G . Conversely, any G -set S is a disjoint union of its orbits. Say $S = \coprod S_i$. Pick $s_i \in S_i$ and denote $G_i \subset G$ its open stabilizer. By Galois theory the fields $(K^{sep})^{G_i}$ are finite separable field extensions of K , and hence the scheme

$$\coprod_i \text{Spec}((K^{sep})^{G_i})$$

is étale over K . This gives an inverse to the functor of the lemma. Some details omitted. \square

Remark 44.56.3. Under the correspondence of the lemma, the coverings in the small étale site $\text{Spec}(K)_{\text{étale}}$ of K correspond to surjective families of maps in G -Sets.

44.57. Galois action on stalks

In this section we define an action of the absolute Galois group of a residue field of a point s of S on the stalk functor at any geometric point lying over s .

Galois action on stalks. Let S be a scheme. Let \bar{s} be a geometric point of S . Let $\sigma \in \text{Aut}(\kappa(\bar{s})/\kappa(s))$. Define an action of σ on the stalk $\mathcal{F}_{\bar{s}}$ of a sheaf \mathcal{F} as follows

$$(44.57.0.1) \quad \begin{array}{ccc} \mathcal{F}_{\bar{s}} & \longrightarrow & \mathcal{F}_{\bar{s}} \\ (U, \bar{u}, t) & \longmapsto & (U, \bar{u} \circ \text{Spec}(\sigma), t). \end{array}$$

where we use the description of elements of the stalk in terms of triples as in the discussion following Definition 44.29.6. This is a left action, since if $\sigma_i \in \text{Aut}(\kappa(\bar{s})/\kappa(s))$ then

$$\begin{aligned} \sigma_1 \cdot (\sigma_2 \cdot (U, \bar{u}, t)) &= \sigma_1 \cdot (U, \bar{u} \circ \text{Spec}(\sigma_2), t) \\ &= (U, \bar{u} \circ \text{Spec}(\sigma_2) \circ \text{Spec}(\sigma_1), t) \\ &= (U, \bar{u} \circ \text{Spec}(\sigma_1 \circ \sigma_2), t) \\ &= (\sigma_1 \circ \sigma_2) \cdot (U, \bar{u}, t) \end{aligned}$$

It is clear that this action is functorial in the sheaf \mathcal{F} . We note that we could have defined this action by referring directly to Remark 44.29.8.

Definition 44.57.1. Let S be a scheme. Let \bar{s} be a geometric point lying over the point s of S . Let $\kappa(s) \subset \kappa(s)^{sep} \subset \kappa(\bar{s})$ denote the separable algebraic closure of $\kappa(s)$ in the algebraically closed field $\kappa(\bar{s})$.

- (1) In this situation the *absolute Galois group* of $\kappa(s)$ is $\text{Gal}(\kappa(s)^{sep}/\kappa(s))$. It is sometimes denoted $\text{Gal}_{\kappa(s)}$.
- (2) The geometric point \bar{s} is called *algebraic* if $\kappa(s) \subset \kappa(\bar{s})$ is an algebraic closure of $\kappa(s)$.

Example 44.57.2. The geometric point $\text{Spec}(\mathbf{C}) \rightarrow \text{Spec}(\mathbf{Q})$ is not algebraic.

Let $\kappa(s) \subset \kappa(s)^{sep} \subset \kappa(\bar{s})$ be as in the definition. Note that as $\kappa(\bar{s})$ is algebraically closed the map

$$\text{Aut}(\kappa(\bar{s})/\kappa(s)) \longrightarrow \text{Gal}(\kappa(s)^{sep}/\kappa(s)) = \text{Gal}_{\kappa(s)}$$

is surjective. Suppose (U, \bar{u}) is an étale neighbourhood of \bar{s} , and say \bar{u} lies over the point u of U . Since $U \rightarrow S$ is étale, the residue field extension $\kappa(s) \subset \kappa(u)$ is finite separable. This implies the following

- (1) If $\sigma \in \text{Aut}(\kappa(\bar{s})/\kappa(s)^{sep})$ then σ acts trivially on $\mathcal{F}_{\bar{s}}$.
- (2) More precisely, the action of $\text{Aut}(\kappa(\bar{s})/\kappa(s))$ determines and is determined by an action of the absolute Galois group $\text{Gal}_{\kappa(s)}$ on $\mathcal{F}_{\bar{s}}$.
- (3) Given (U, \bar{u}, t) representing an element ξ of $\mathcal{F}_{\bar{s}}$ any element of $\text{Gal}(\kappa(s)^{sep}/K)$ acts trivially, where $\kappa(s) \subset K \subset \kappa(s)^{sep}$ is the image of $\bar{u}^\sharp : \kappa(u) \rightarrow \kappa(\bar{s})$.

Altogether we see that $\mathcal{F}_{\bar{s}}$ becomes a $\text{Gal}_{\kappa(s)}$ -set (see Definition 44.56.1). Hence we may think of the stalk functor as a functor

$$\text{Sh}(S_{\text{étale}}) \longrightarrow \text{Gal}_{\kappa(s)}\text{-Sets}, \quad \mathcal{F} \longmapsto \mathcal{F}_{\bar{s}}$$

and from now on we usually do think about the stalk functor in this way.

Theorem 44.57.3. *Let $S = \text{Spec}(K)$ with K a field. Let \bar{s} be a geometric point of S . Let $G = \text{Gal}_{\kappa(s)}$ denote the absolute Galois group. Taking stalks induces an equivalence of categories*

$$\text{Sh}(S_{\text{étale}}) \longrightarrow G\text{-Sets}, \quad \mathcal{F} \longmapsto \mathcal{F}_{\bar{s}}.$$

Proof. Let us construct the inverse to this functor. In Lemma 44.56.2 we have seen that given a G -set M there exists an étale morphism $X \rightarrow \text{Spec}(K)$ such that $\text{Mor}_K(\text{Spec}(K^{sep}), X)$ is isomorphic to M as a G -set. Consider the sheaf \mathcal{F} on $\text{Spec}(K)_{\text{étale}}$ defined by the rule $U \mapsto \text{Mor}_K(U, X)$. This is a sheaf as the étale topology is subcanonical. Then we see that $\mathcal{F}_{\bar{s}} = \text{Mor}_K(\text{Spec}(K^{sep}), X) = M$ as G -sets (details omitted). This gives the inverse of the functor and we win. \square

Remark 44.57.4. Another way to state the conclusions of Lemmas 44.56.2 and Theorem 44.57.3 is to say that every sheaf on $\text{Spec}(K)_{\text{étale}}$ is representable by a scheme X étale over $\text{Spec}(K)$. This does not mean that every sheaf is representable in the sense of Sites, Definition 7.13.3. The reason is that in our construction of $\text{Spec}(K)_{\text{étale}}$ we chose a sufficiently large set of schemes étale over $\text{Spec}(K)$, whereas sheaves on $\text{Spec}(K)_{\text{étale}}$ form a proper class.

Lemma 44.57.5. *Assumptions and notations as in Theorem 44.57.3. There is a functorial bijection*

$$\Gamma(S, \mathcal{F}) = (\mathcal{F}_{\bar{s}})^G$$

Proof. We can prove this using formal arguments and the result of Theorem 44.57.3 as follows. Given a sheaf \mathcal{F} corresponding to the G -set $M = \mathcal{F}_{\bar{s}}$ we have

$$\begin{aligned}\Gamma(S, \mathcal{F}) &= \text{Mor}_{Sh(S_{\acute{e}tale})}(h_{\text{Spec}(K)}, \mathcal{F}) \\ &= \text{Mor}_{G\text{-Sets}}(\{*\}, M) \\ &= M^G\end{aligned}$$

Here the first identification is explained in Sites, Sections 7.2 and 7.13, the second results from Theorem 44.57.3 and the third is clear. We will also give a direct proof⁴.

Suppose that $t \in \Gamma(S, \mathcal{F})$ is a global section. Then the triple (S, \bar{s}, t) defines an element of $\mathcal{F}_{\bar{s}}$ which is clearly invariant under the action of G . Conversely, suppose that (U, \bar{u}, t) defines an element of $\mathcal{F}_{\bar{s}}$ which is invariant. Then we may shrink U and assume $U = \text{Spec}(L)$ for some finite separable field extension of K , see Proposition 44.26.2. In this case the map $\mathcal{F}(U) \rightarrow \mathcal{F}_{\bar{s}}$ is injective, because for any morphism of étale neighbourhoods $(U', \bar{u}') \rightarrow (U, \bar{u})$ the restriction map $\mathcal{F}(U) \rightarrow \mathcal{F}(U')$ is injective since $U' \rightarrow U$ is a covering of $S_{\acute{e}tale}$. After enlarging L a bit we may assume $K \subset L$ is a finite Galois extension. At this point we use that

$$\text{Spec}(L) \times_{\text{Spec}(K)} \text{Spec}(L) = \coprod_{\sigma \in \text{Gal}(L/K)} \text{Spec}(L)$$

where the maps $\text{Spec}(L) \rightarrow \text{Spec}(L \otimes_K L)$ come from the ring maps $a \otimes b \mapsto a\sigma(b)$. Hence we see that the condition that (U, \bar{u}, t) is invariant under all of G implies that $t \in \mathcal{F}(\text{Spec}(L))$ maps to the same element of $\mathcal{F}(\text{Spec}(L) \times_{\text{Spec}(K)} \text{Spec}(L))$ via restriction by either projection (this uses the injectivity mentioned above; details omitted). Hence the sheaf condition of \mathcal{F} for the étale covering $\{\text{Spec}(L) \rightarrow \text{Spec}(K)\}$ kicks in and we conclude that t comes from a unique section of \mathcal{F} over $\text{Spec}(K)$. \square

Remark 44.57.6. Let S be a scheme and let $\bar{s} : \text{Spec}(k) \rightarrow S$ be a geometric point of S . By definition this means that k is algebraically closed. In particular the absolute Galois group of k is trivial. Hence by Theorem 44.57.3 the category of sheaves on $\text{Spec}(k)_{\acute{e}tale}$ is equivalent to the category of sets. The equivalence is given by taking sections over $\text{Spec}(k)$. This finally provides us with an alternative definition of the stalk functor. Namely, the functor

$$Sh(S_{\acute{e}tale}) \longrightarrow \text{Sets}, \quad \mathcal{F} \longmapsto \mathcal{F}_{\bar{s}}$$

is isomorphic to the functor

$$Sh(S_{\acute{e}tale}) \longrightarrow Sh(\text{Spec}(k)_{\acute{e}tale}) = \text{Sets}, \quad \mathcal{F} \longmapsto \bar{s}^* \mathcal{F}$$

To prove this rigorously one can use Lemma 44.36.2 part (3) with $f = \bar{s}$. Moreover, having said this the general case of Lemma 44.36.2 part (3) follows from functoriality of pullbacks.

⁴For the doubting Thomases out there.

44.58. Group cohomology

Notation. If we write $H^i(G, M)$ we will mean that G is a topological group and M a discrete G -module with continuous G -action. This includes the case of an abstract group G , which simply means that G is viewed as a topological group with the discrete topology. When the module has a nondiscrete topology, we will use the notation $H_{cont}^i(G, M)$ to indicate the cohomology theory discussed in [Tat76].

Definition 44.58.1. Let G be a topological group. A G -module, sometime called a *discrete G -module*, is an abelian group M endowed with a left action $a : G \times M \rightarrow M$ by group homomorphisms such that a is continuous when M is given the discrete topology and $G \times M$ the product topology. A *morphism of G -modules* $f : M \rightarrow N$ is simply any G -equivariant homomorphism from M to N . The category of G -modules is denoted Mod_G .

The condition that $a : G \times M \rightarrow M$ is continuous is equivalent with the condition that the stabilizer of any $x \in M$ is open in G . If G is an abstract group then this corresponds to the notion of an abelian group endowed with a G -action provided we endow G with the discrete topology.

The category Mod_G has enough injectives, see Injectives, Lemma 19.3.1. Consider the left exact functor

$$Mod_G \longrightarrow Ab, \quad M \longmapsto M^G = \{x \in M \mid g \cdot x = x \ \forall g \in G\}$$

We sometimes denote $M^G = H^0(G, M)$ and sometimes we write $M^G = \Gamma_G(M)$. This functor has a total right derived functor $R\Gamma_G(M)$ and i th right derived functor $R^i\Gamma_G(M) = H^i(G, M)$ for any $i \geq 0$.

Definition 44.58.2. Let G be a topological group. Let M be a G -module.

- (1) The right derived functors $H^i(G, M)$ are called the *continuous group cohomology groups* of M .
- (2) If G is an abstract group endowed with the discrete topology then the $H^i(G, M)$ are called the *group cohomology groups* of M .
- (3) If G is a Galois group, then the groups $H^i(G, M)$ are called the *Galois cohomology groups* of M .
- (4) If G is the absolute Galois group of a field K , then the groups $H^i(G, M)$ are sometimes called the *Galois cohomology groups of K with coefficients in M* . In this case we sometimes write $H^i(K, M)$ instead of $H^i(G, M)$.

We can compute continuous group cohomology by the complex of inhomogeneous cochains. In fact, we can define this when M is an arbitrary topological abelian group endowed with a continuous G -action. Namely, we consider the complex

$$C_{cont}^\bullet(G, M) : M \rightarrow \text{Maps}_{cont}(G, M) \rightarrow \text{Maps}_{cont}(G \times G, M) \rightarrow \dots$$

where the boundary map is defined for $n \geq 1$ by the rule

$$\begin{aligned} d(f)(g_1, \dots, g_{n+1}) &= g_1(f(g_2, \dots, g_{n+1})) \\ &\quad + \sum_{j=1, \dots, n} (-1)^j f(g_1, \dots, g_j g_{j+1}, \dots, g_{n+1}) \\ &\quad + (-1)^{n+1} f(g_1, \dots, g_n) \end{aligned}$$

and for $n = 0$ sends $m \in M$ to the map $g \mapsto g(m) - m$. We define

$$H_{cont}^i(G, M) = H^i(C_{cont}^\bullet(G, M))$$

Since the terms of the complex involve continuous maps from G and self products of G into the topological module M , it is not clear that this turns a short exact sequence of topological modules into a long exact cohomology sequence. (One difficulty is that the category of topological abelian groups isn't an abelian category!) However, this is true when the topology on the modules is discrete. In fact, if M is a G -module as in Definition 44.58.1, then there is a canonical isomorphism

$$H^i(G, M) = H_{cont}^i(G, M)$$

of cohomology groups.

44.59. Cohomology of a point

As a consequence of the discussion in the preceding sections we obtain the equivalence of étale cohomology of the spectrum of a field with Galois cohomology.

Lemma 44.59.1. *Let $S = \text{Spec}(K)$ with K a field. Let \bar{s} be a geometric point of S . Let $G = \text{Gal}_{\kappa(\bar{s})}$ denote the absolute Galois group. The stalk functor induces an equivalence of categories*

$$\text{Ab}(S_{\text{étale}}) \longrightarrow \text{Mod}_G, \quad \mathcal{F} \longmapsto \mathcal{F}_{\bar{s}}.$$

Proof. In Theorem 44.57.3 we have seen the equivalence between sheaves of sets and G -sets. The current lemma follows formally from this as an abelian sheaf is just a sheaf of sets endowed with a commutative group law, and a G -module is just a G -set endowed with a commutative group law. \square

Lemma 44.59.2. *Notation and assumptions as in Lemma 44.59.1. Let \mathcal{F} be an abelian sheaf on $\text{Spec}(K)_{\text{étale}}$ which corresponds to the G -module M . Then*

- (1) *in $D(\text{Ab})$ we have a canonical isomorphism $R\Gamma(S, \mathcal{F}) = R\Gamma_G(M)$,*
- (2) *$H_{\text{étale}}^0(S, \mathcal{F}) = M^G$, and*
- (3) *$H_{\text{étale}}^q(S, \mathcal{F}) = H^q(G, M)$.*

Proof. Combine Lemma 44.59.1 with Lemma 44.57.5. \square

Example 44.59.3. Sheaves on $\text{Spec}(K)_{\text{étale}}$. Let $G = \text{Gal}(K^{\text{sep}}/K)$ be the absolute Galois group of K .

- (1) The constant sheaf $\underline{\mathbf{Z}/n\mathbf{Z}}$ corresponds to the module $\mathbf{Z}/n\mathbf{Z}$ with trivial G -action,
- (2) the sheaf $\mathbf{G}_m|_{\text{Spec}(K)_{\text{étale}}}$ corresponds to $(K^{\text{sep}})^*$ with its G -action,
- (3) the sheaf $\mathbf{G}_a|_{\text{Spec}(K^{\text{sep}})}$ corresponds to $(K^{\text{sep}}, +)$ with its G -action, and
- (4) the sheaf $\mu_n|_{\text{Spec}(K^{\text{sep}})}$ corresponds to $\mu_n(K^{\text{sep}})$ with its G -action.

By Remark 44.23.4 and Theorem 44.24.1 we have the following identifications for cohomology groups:

$$\begin{aligned} H_{\text{étale}}^0(S_{\text{étale}}, \mathbf{G}_m) &= \Gamma(S, \mathcal{O}_S^*) \\ H_{\text{étale}}^1(S_{\text{étale}}, \mathbf{G}_m) &= H_{\text{Zar}}^1(S, \mathcal{O}_S^*) = \text{Pic}(S) \\ H_{\text{étale}}^i(S_{\text{étale}}, \mathbf{G}_a) &= H_{\text{Zar}}^i(S, \mathcal{O}_S) \end{aligned}$$

Also, for any quasi-coherent sheaf \mathcal{F} on $S_{\text{étale}}$ we have

$$H^i(S_{\text{étale}}, \mathcal{F}) = H_{\text{Zar}}^i(S, \mathcal{F}),$$

see Theorem 44.22.4. In particular, this gives the following sequence of equalities

$$0 = \text{Pic}(\text{Spec}(K)) = H_{\text{étale}}^1(\text{Spec}(K)_{\text{étale}}, \mathbf{G}_m) = H^1(G, (K^{\text{sep}})^*)$$

which is none other than Hilbert's 90 theorem. Similarly, for $i \geq 1$,

$$0 = H^i(\mathrm{Spec}(K), \mathcal{O}) = H_{\acute{e}tale}^i(\mathrm{Spec}(K)_{\acute{e}tale}, \mathbf{G}_a) = H^i(G, K^{sep})$$

where the K^{sep} indicates K^{sep} as a Galois module with addition as group law. In this way we may consider the work we have done so far as a complicated way of computing Galois cohomology groups.

44.60. Cohomology of curves

The next task at hand is to compute the étale cohomology of a smooth curve over an algebraically closed field with torsion coefficients, and in particular show that it vanishes in degree at least 3. To prove this, we will compute cohomology at the generic point, which amounts to some Galois cohomology.

44.61. Brauer groups

Brauer groups of fields are defined using finite central simple algebras. In this section we review the relevant facts about Brauer groups, most of which are discussed in the chapter Brauer Groups, Section 11.1. For other references, see [Ser62], [Ser97] or [Wei48].

Theorem 44.61.1. *Let K be a field. For a unital, associative (not necessarily commutative) K -algebra A the following are equivalent*

- (1) A is finite central simple K -algebra,
- (2) A is a finite dimensional K -vector space, K is the center of A , and A has no nontrivial two-sided ideal,
- (3) there exists $d \geq 1$ such that $A \otimes_K \bar{K} \cong \mathrm{Mat}(d \times d, \bar{K})$,
- (4) there exists $d \geq 1$ such that $A \otimes_K K^{sep} \cong \mathrm{Mat}(d \times d, K^{sep})$,
- (5) there exist $d \geq 1$ and a finite Galois extension $K \subset K'$ such that $A \otimes_{K'} K' \cong \mathrm{Mat}(d \times d, K')$,
- (6) there exist $n \geq 1$ and a finite central skew field D over K such that $A \cong \mathrm{Mat}(n \times n, D)$.

The integer d is called the degree of A .

Proof. This is a copy of Brauer Groups, Lemma 11.8.6. □

Lemma 44.61.2. *Let A be a finite central simple algebra over K . Then*

$$\begin{aligned} A \otimes_K A^{opp} &\longrightarrow \mathrm{End}_K(A) \\ a \otimes a' &\longmapsto (x \mapsto axa') \end{aligned}$$

is an isomorphism of algebras over K .

Proof. See Brauer Groups, Lemma 11.4.10. □

Definition 44.61.3. Two finite central simple algebras A_1 and A_2 over K are called *similar*, or *equivalent* if there exist $m, n \geq 1$ such that $\mathrm{Mat}(n \times n, A_1) \cong \mathrm{Mat}(m \times m, A_2)$. We write $A_1 \sim A_2$.

By Brauer Groups, Lemma 11.5.1 this is an equivalence relation.

Definition 44.61.4. Let K be a field. The *Brauer group* of K is the set $\mathrm{Br}(K)$ of similarity classes of finite central simple algebras over K , endowed with the group law induced by tensor product (over K). The class of A in $\mathrm{Br}(K)$ is denoted by $[A]$. The neutral element is $[K] = [\mathrm{Mat}(d \times d, K)]$ for any $d \geq 1$.

The previous lemma implies that inverses exist and that $-[A] = [A^{opp}]$. The Brauer group of a field is always torsion. In fact, we will see that $[A]$ has order $\deg(A)$ for any finite central simple algebra A (see Lemma 44.62.2). In general the Brauer group is not finitely generated, for example the Brauer group of a non-Archimedean local field is \mathbf{Q}/\mathbf{Z} . The Brauer group of $\mathbf{C}(x, y)$ is uncountable.

Lemma 44.61.5. *Let K be a field and let K^{sep} be a separable algebraic closure. Then the set of isomorphism classes of central simple algebras of degree d over K is in bijection with the non-abelian cohomology $H^1(\text{Gal}(K^{sep}/K), \text{PGL}_d(K^{sep}))$.*

Sketch of proof. The Skolem-Noether theorem (see Brauer Groups, Theorem 11.6.1) implies that for any field L the group $\text{Aut}_{L\text{-Algebras}}(\text{Mat}_d(L))$ equals $\text{PGL}_d(L)$. By Theorem 44.61.1, we see that central simple algebras of degree d correspond to forms of the K -algebra $\text{Mat}_d(K)$. Combined we see that isomorphism classes of degree d central simple algebras correspond to elements of $H^1(\text{Gal}(K^{sep}/K), \text{PGL}_d(K^{sep}))$. For more details on twisting, see for example [Sil86]. \square

If A is a finite central simple algebra of degree d over a field K , we denote ξ_A the corresponding cohomology class in $H^1(\text{Gal}(K^{sep}/K), \text{PGL}_d(K^{sep}))$. Consider the short exact sequence

$$1 \rightarrow (K^{sep})^* \rightarrow \text{GL}_d(K^{sep}) \rightarrow \text{PGL}_d(K^{sep}) \rightarrow 1,$$

which gives rise to a long exact cohomology sequence (up to degree 2) with coboundary map

$$\delta_d : H^1(\text{Gal}(K^{sep}/K), \text{PGL}_d(K^{sep})) \rightarrow H^2(\text{Gal}(K^{sep}/K), (K^{sep})^*).$$

Explicitly, this is given as follows: if ξ is a cohomology class represented by the 1-cocycle (g_σ) , then $\delta_d(\xi)$ is the class of the 2-cocycle

$$(44.61.5.1) \quad (\sigma, \tau) \mapsto \tilde{g}_\sigma^{-1} \tilde{g}_{\sigma\tau} \tilde{g}_\tau^{-1} \in (K^{sep})^*$$

where $\tilde{g}_\sigma \in \text{GL}_d(K^{sep})$ is a lift of g_σ . Using this we can make explicit the map

$$\delta : \text{Br}(K) \rightarrow H^2(\text{Gal}(K^{sep}/K), (K^{sep})^*), \quad [A] \mapsto \delta_{\deg A}(\xi_A)$$

as follows. Assume A has degree d over K . Choose an isomorphism $\varphi : \text{Mat}_d(K^{sep}) \rightarrow A \otimes_K K^{sep}$. For $\sigma \in \text{Gal}(K^{sep}/K)$ choose an element $\tilde{g}_\sigma \in \text{GL}_d(K^{sep})$ such that $\varphi^{-1} \circ \sigma(\varphi)$ is equal to the map $x \mapsto \tilde{g}_\sigma x \tilde{g}_\sigma^{-1}$. The class in H^2 is defined by the two cocycle (44.61.5.1).

Theorem 44.61.6. *Let K be a field with separable algebraic closure K^{sep} . The map $\delta : \text{Br}(K) \rightarrow H^2(\text{Gal}(K^{sep}/K), (K^{sep})^*)$ defined above is a group isomorphism.*

Sketch of proof. In the abelian case ($d = 1$), one has the identification

$$H^1(\text{Gal}(K^{sep}/K), \text{GL}_d(K^{sep})) = H^1_{\text{étale}}(\text{Spec}(K), \text{GL}_d(\mathcal{O}))$$

the latter of which is trivial by fpqc descent. If this were true in the non-abelian case, this would readily imply injectivity of δ . (See [Del77].) Rather, to prove this, one can reinterpret $\delta([A])$ as the obstruction to the existence of a K -vector space V with a left A -module structure and such that $\dim_K V = \deg A$. In the case where V exists, one has $A \cong \text{End}_K(V)$. For surjectivity, pick a cohomology class $\xi \in H^2(\text{Gal}(K^{sep}/K), (K^{sep})^*)$, then there exists a finite Galois extension $K \subset K' \subset K^{sep}$ such that ξ is the image of some $\xi' \in H^2(\text{Gal}(K'|K), (K')^*)$. Then write down an explicit central simple algebra over K using the data K', ξ' . \square

44.62. The Brauer group of a scheme

Let S be a scheme. An \mathcal{O}_S -algebra \mathcal{A} is called *Azumaya* if it is étale locally a matrix algebra, i.e., if there exists an étale covering $\mathcal{U} = \{\varphi_i : U_i \rightarrow S\}_{i \in I}$ such that $\varphi_i^* \mathcal{A} \cong \text{Mat}_{d_i}(\mathcal{O}_{U_i})$ for some $d_i \geq 1$. Two such \mathcal{A} and \mathcal{B} are called *equivalent* if there exist finite locally free \mathcal{O}_S -modules \mathcal{F} and \mathcal{G} which have positive rank at every $s \in S$ such that

$$\mathcal{A} \otimes_{\mathcal{O}_S} \text{Hom}_{\mathcal{O}_S}(\mathcal{F}, \mathcal{F}) \cong \mathcal{B} \otimes_{\mathcal{O}_S} \text{Hom}_{\mathcal{O}_S}(\mathcal{G}, \mathcal{G})$$

as \mathcal{O}_S -algebras. The *Brauer group* of S is the set $\text{Br}(S)$ of equivalence classes of Azumaya \mathcal{O}_S -algebras with the operation induced by tensor product (over \mathcal{O}_S).

Lemma 44.62.1. *Let S be a scheme. Let \mathcal{F} and \mathcal{G} be finite locally free sheaves of \mathcal{O}_S -modules of positive rank. If there exists an isomorphism $\text{Hom}_{\mathcal{O}_S}(\mathcal{F}, \mathcal{F}) \cong \text{Hom}_{\mathcal{O}_S}(\mathcal{G}, \mathcal{G})$ of \mathcal{O}_S -algebras, then there exists an invertible sheaf \mathcal{L} on S such that $\mathcal{F} \otimes_{\mathcal{O}_S} \mathcal{L} \cong \mathcal{G}$ and such that this isomorphism induces the given isomorphism of endomorphism algebras.*

Proof. Fix an isomorphism $\text{Hom}_{\mathcal{O}_S}(\mathcal{F}, \mathcal{F}) \rightarrow \text{Hom}_{\mathcal{O}_S}(\mathcal{G}, \mathcal{G})$. Consider the sheaf $\mathcal{L} \subset \text{Hom}(\mathcal{F}, \mathcal{G})$ generated as an \mathcal{O}_S -module by the local isomorphisms $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ such that conjugation by φ is the given isomorphism of endomorphism algebras. A local calculation (reducing to the case that \mathcal{F} and \mathcal{G} are finite free and S is affine) shows that \mathcal{L} is invertible. Another local calculation shows that the evaluation map

$$\mathcal{F} \otimes_{\mathcal{O}_S} \mathcal{L} \longrightarrow \mathcal{G}$$

is an isomorphism. □

The argument given in the proof of the following lemma can be found in [Sal81].

Lemma 44.62.2. *Let S be a scheme. Let \mathcal{A} be an Azumaya algebra which is locally free of rank d^2 over S . Then the class of \mathcal{A} in the Brauer group of S is annihilated by d .*

Proof. Choose an étale covering $\{U_i \rightarrow S\}$ and choose isomorphisms $\mathcal{A}|_{U_i} \rightarrow \text{Hom}(\mathcal{F}_i, \mathcal{F}_i)$ for some locally free \mathcal{O}_{U_i} -modules \mathcal{F}_i of rank d . (We may assume \mathcal{F}_i is free.) Consider the composition

$$p_i : \mathcal{F}_i^{\otimes d} \rightarrow \wedge^d(\mathcal{F}_i) \rightarrow \mathcal{F}_i^{\otimes d}$$

The first arrow is the usual projection and the second arrow is the isomorphism of the top exterior power of \mathcal{F}_i with the submodule of sections of $\mathcal{F}_i^{\otimes d}$ which transform according to the sign character under the action of the symmetric group on d letters. Then $p_i^2 = p_i$ and the rank of p_i is 1. Using the given isomorphism $\mathcal{A}|_{U_i} \rightarrow \text{Hom}(\mathcal{F}_i, \mathcal{F}_i)$ and the canonical isomorphism

$$\text{Hom}(\mathcal{F}_i, \mathcal{F}_i)^{\otimes d} = \text{Hom}(\mathcal{F}_i^{\otimes d}, \mathcal{F}_i^{\otimes d})$$

we may think of p_i as a section of $\mathcal{A}^{\otimes d}$ over U_i . We claim that $p_i|_{U_i \times_S U_j} = p_j|_{U_i \times_S U_j}$ as sections of $\mathcal{A}^{\otimes d}$. Namely, applying Lemma 44.62.1 we obtain an invertible sheaf \mathcal{L}_{ij} and a canonical isomorphism

$$\mathcal{F}_i|_{U_i \times_S U_j} \otimes \mathcal{L}_{ij} \longrightarrow \mathcal{F}_j|_{U_i \times_S U_j}.$$

Using this isomorphism we see that p_i maps to p_j . Since $\mathcal{A}^{\otimes d}$ is a sheaf on $S_{\text{étale}}$ (Proposition 44.17.1) we find a canonical global section $p \in \Gamma(S, \mathcal{A}^{\otimes d})$. A local calculation shows that

$$\mathcal{H} = \text{Im}(\mathcal{A}^{\otimes d} \rightarrow \mathcal{A}^{\otimes d}, f \mapsto fp)$$

is a locally free module of rank d^d and that (left) multiplication by $\mathcal{A}^{\otimes d}$ induces an isomorphism $\mathcal{A}^{\otimes d} \rightarrow \text{Hom}(\mathcal{H}, \mathcal{H})$. In other words, $\mathcal{A}^{\otimes d}$ is the trivial element of the Brauer group of S as desired. \square

In this setting, the analogue of the isomorphism δ of Theorem 44.61.6 is a map

$$\delta_S : \text{Br}(S) \rightarrow H_{\text{étale}}^2(S, \mathbf{G}_m).$$

It is true that δ_S is injective. If S is quasi-compact or connected, then $\text{Br}(S)$ is a torsion group, so in this case the image of δ_S is contained in the *cohomological Brauer group* of S

$$\text{Br}'(S) := H_{\text{étale}}^2(S, \mathbf{G}_m)_{\text{torsion}}.$$

So if S is quasi-compact or connected, there is an inclusion $\text{Br}(S) \subset \text{Br}'(S)$. This is not always an equality: there exists a nonseparated singular surface S for which $\text{Br}(S) \subset \text{Br}'(S)$ is a strict inclusion. If S is quasi-projective, then $\text{Br}(S) = \text{Br}'(S)$. However, it is not known whether this holds for a smooth proper variety over \mathbf{C} , say.

44.63. Galois cohomology

In this section we will use the following result from Galois cohomology to get vanishing of higher étale cohomology groups over the spectrum of a field.

Proposition 44.63.1. *Let K be a field with separable algebraic closure K^{sep} . Assume that for any finite extension K' of K we have $\text{Br}(K') = 0$. Then*

- (1) $H^q(\text{Gal}(K^{\text{sep}}/K), (K^{\text{sep}})^*) = 0$ for all $q \geq 1$, and
- (2) $H^q(\text{Gal}(K^{\text{sep}}/K), M) = 0$ for any torsion $\text{Gal}(K^{\text{sep}}/K)$ -module M and any $q \geq 2$,

Proof. Omitted. \square

Definition 44.63.2. A field K is called C_r if for every $0 < d^r < n$ and every $f \in K[T_1, \dots, T_n]$ homogeneous of degree d , there exist $\alpha = (\alpha_1, \dots, \alpha_n)$, $\alpha_i \in K$ not all zero, such that $f(\alpha) = 0$. Such an α is called a *nontrivial solution* of f .

Example 44.63.3. An algebraically closed field is C_r .

In fact, we have the following simple lemma.

Lemma 44.63.4. *Let k be an algebraically closed field. Let $f_1, \dots, f_s \in k[T_1, \dots, T_n]$ be homogeneous polynomials of degree d_1, \dots, d_s with $d_i > 0$. If $s < n$, then $f_1 = \dots = f_s = 0$ have a common nontrivial solution.*

Proof. Omitted. \square

The following result computes the Brauer group of C_1 fields.

Theorem 44.63.5. *Let K be a C_1 field. Then $\text{Br}(K) = 0$.*

Proof. Let D be a finite dimensional division algebra over K with center K . We have seen that

$$D \otimes_K K^{sep} \cong \text{Mat}_d(K^{sep})$$

uniquely up to inner isomorphism. Hence the determinant $\det : \text{Mat}_d(K^{sep}) \rightarrow K^{sep}$ is Galois invariant and descends to a homogeneous degree d map

$$\det = N_{\text{red}} : D \rightarrow K$$

called the *reduced norm*. Since K is C_1 , if $d > 1$, then there exists a nonzero $x \in D$ with $N_{\text{red}}(x) = 0$. This clearly implies that x is not invertible, which is a contradiction. Hence $\text{Br}(K) = 0$. \square

Definition 44.63.6. Let k be a field. A *variety* is separated, integral scheme of finite type over k . A *curve* is a variety of dimension 1.

Theorem 44.63.7 (Tsen's theorem). *The function field of a variety of dimension r over an algebraically closed field k is C_r .*

Proof. For projective space one can show directly that the field $k(x_1, \dots, x_r)$ is C_r (exercise).

General case. Without loss of generality, we may assume X to be projective. Let $f \in K[T_1, \dots, T_n]_d$ with $0 < d^r < n$. Say the coefficients of f are in $\Gamma(X, \mathcal{O}_X(H))$ for some ample $H \subset X$. Let $\alpha = (\alpha_1, \dots, \alpha_n)$ with $\alpha_i \in \Gamma(X, \mathcal{O}_X(eH))$. Then $f(\alpha) \in \Gamma(X, \mathcal{O}_X((de+1)H))$. Consider the system of equations $f(\alpha) = 0$. Then by asymptotic Riemann-Roch,

- the number of variables is $n \dim_K \Gamma(X, \mathcal{O}_X(eH)) \sim n \frac{e^r}{r!} (H^r)$, and
- the number of equations is $\dim_K \Gamma(X, \mathcal{O}_X((de+1)H)) \sim \frac{(de+1)^r}{r!} (H^r)$.

Since $n > d^r$, there are more variables than equations, and since there is a trivial solution, there are also nontrivial solutions. \square

Lemma 44.63.8. *Let C be a curve over an algebraically closed field k . Then the Brauer group of the function field of C is zero: $\text{Br}(k(C)) = 0$.*

Proof. This is clear from Tsen's theorem, Theorem 44.63.7. \square

Lemma 44.63.9. *Let k be an algebraically closed field and $k \subset K$ a field extension of transcendence degree 1. Then for all $q \geq 1$, $H_{\text{étale}}^q(\text{Spec}(K), \mathbf{G}_m) = 0$.*

Proof. Recall that $H_{\text{étale}}^q(\text{Spec}(K), \mathbf{G}_m) = H^q(\text{Gal}(K^{sep}/K), (K^{sep})^*)$ by Lemma 44.59.2. Thus by Proposition 44.63.1 it suffices to show that if $K \subset K'$ is a finite field extension, then $\text{Br}(K') = 0$. Now observe that $K' = \text{colim } K''$, where K'' runs over the finitely generated subextensions of k contained in K' of transcendence degree 1. Note that $\text{Br}(K') = \text{colim } \text{Br}(K'')$ which reduces us to a finitely generated field extension K''/k of transcendence degree 1. Such a field is the function field of a curve over k , hence has trivial Brauer group by Lemma 44.63.8. \square

44.64. Higher vanishing for the multiplicative group

In this section, we fix an algebraically closed field k and a smooth curve X over k . We denote $i_x : x \hookrightarrow X$ the inclusion of a closed point of X and $j : \eta \hookrightarrow X$ the inclusion of the generic point. We also denote X^0 the set of closed points of X .

Theorem 44.64.1 (The Fundamental Exact Sequence). *There is a short exact sequence of étale sheaves on X*

$$0 \rightarrow \mathbf{G}_{m,X} \rightarrow j_*\mathbf{G}_{m,\eta} \rightarrow \bigoplus_{x \in X^0} i_{x*}\mathbf{Z} \rightarrow 0.$$

Proof. Let $\varphi : U \rightarrow X$ be an étale morphism. Then by properties of étale morphisms (Proposition 44.26.2), $U = \coprod_i U_i$ where each U_i is a smooth curve mapping to X . The above sequence for X is a product of the corresponding sequences for each U_i , so it suffices to treat the case where U is connected, hence irreducible. In this case, there is a well known exact sequence

$$1 \rightarrow \Gamma(U, \mathcal{O}_U^*) \rightarrow k(U)^* \rightarrow \bigoplus_{y \in U^0} \mathbf{Z}_y.$$

This amounts to a sequence

$$0 \rightarrow \Gamma(U, \mathcal{O}_U^*) \rightarrow \Gamma(\eta \times_X U, \mathcal{O}_{\eta \times_X U}^*) \rightarrow \bigoplus_{x \in X^0} \Gamma(x \times_X U, \mathbf{Z})$$

which, unfolding definitions, is nothing but a sequence

$$0 \rightarrow \mathbf{G}_m(U) \rightarrow j_*\mathbf{G}_{m,\eta}(U) \rightarrow \left(\bigoplus_{x \in X^0} i_{x*}\mathbf{Z} \right) (U).$$

This defines the maps in the Fundamental Exact Sequence and shows it is exact except possibly at the last step. To see surjectivity, let us recall that if U is a nonsingular curve and D is a divisor on U , then there exists a Zariski open covering $\{U_j \rightarrow U\}$ of U such that $D|_{U_j} = \text{div}(f_j)$ for some $f_j \in k(U)^*$. \square

Lemma 44.64.2. *For any $q \geq 1$, $R^q j_*\mathbf{G}_{m,\eta} = 0$.*

Proof. We need to show that $(R^q j_*\mathbf{G}_{m,\eta})_{\bar{x}} = 0$ for every geometric point \bar{x} of X .

Assume that \bar{x} lies over a closed point x of X . Let $\text{Spec}(A)$ be an affine open neighbourhood of x in X , and K the fraction field of A . Then

$$\text{Spec}(\mathcal{O}_{X,\bar{x}}^{sh}) \times_X \eta = \text{Spec}(\mathcal{O}_{X,\bar{x}}^{sh} \otimes_A K).$$

The ring $\mathcal{O}_{X,\bar{x}}^{sh} \otimes_A K$ is a localization of the discrete valuation ring $\mathcal{O}_{X,\bar{x}}^{sh}$, so it is either $\mathcal{O}_{X,\bar{x}}^{sh}$ again, or its fraction field $K_{\bar{x}}^{sh}$. But since some local uniformizer gets inverted, it must be the latter. Hence

$$(R^q j_*\mathbf{G}_{m,\eta})_{(X,\bar{x})} = H_{\acute{e}tale}^q(\text{Spec } K_{\bar{x}}^{sh}, \mathbf{G}_m).$$

Now recall that $\mathcal{O}_{X,\bar{x}}^{sh} = \text{colim}_{(U,\bar{u}) \rightarrow \bar{x}} \mathcal{O}(U) = \text{colim}_{A \subset B} B$ where $A \rightarrow B$ is étale, hence $K_{\bar{x}}^{sh}$ is an algebraic extension of $K = k(X)$, and we may apply Lemma 44.63.9 to get the vanishing.

Assume that $\bar{x} = \bar{\eta}$ lies over the generic point η of X (in fact, this case is superfluous). Then $\mathcal{O}_{X,\bar{\eta}} = \kappa(\eta)^{sep}$ and thus

$$\begin{aligned} (R^q j_*\mathbf{G}_{m,\eta})_{\bar{\eta}} &= H_{\acute{e}tale}^q(\text{Spec}(\kappa(\eta)^{sep}) \times_X \eta, \mathbf{G}_m) \\ &= H_{\acute{e}tale}^q(\text{Spec}(\kappa(\eta)^{sep}), \mathbf{G}_m) \\ &= 0 \quad \text{for } q \geq 1 \end{aligned}$$

since the corresponding Galois group is trivial. \square

Lemma 44.64.3. *For all $p \geq 1$, $H_{\acute{e}tale}^p(X, j_*\mathbf{G}_{m,\eta}) = 0$.*

Proof. The Leray spectral sequence reads

$$E_2^{p,q} = H_{\acute{e}tale}^p(X, R^q j_* \mathbf{G}_{m,\eta}) \Rightarrow H_{\acute{e}tale}^{p+q}(\eta, \mathbf{G}_{m,\eta}),$$

which vanishes for $p + q \geq 1$ by Lemma 44.63.9. Taking $q = 0$, we get the desired vanishing. \square

Lemma 44.64.4. *For all $q \geq 1$, $H_{\acute{e}tale}^q(X, \bigoplus_{x \in X^0} i_{x*} \mathbf{Z}) = 0$.*

Proof. For X quasi-compact and quasi-separated, cohomology commutes with colimits, so it suffices to show the vanishing of $H_{\acute{e}tale}^q(X, i_{x*} \mathbf{Z})$. But then the inclusion i_x of a closed point is finite so $R^p i_{x*} \mathbf{Z} = 0$ for all $p \geq 1$ by Proposition 44.55.2. Applying the Leray spectral sequence, we see that $H_{\acute{e}tale}^q(X, i_{x*} \mathbf{Z}) = H_{\acute{e}tale}^q(x, \mathbf{Z})$. Finally, since x is the spectrum of an algebraically closed field, all higher cohomology on x vanishes. \square

Concluding this series of lemmata, we get the following result.

Theorem 44.64.5. *Let X be a smooth curve over an algebraically closed field. Then*

$$H_{\acute{e}tale}^q(X, \mathbf{G}_m) = 0 \quad \text{for all } q \geq 2.$$

Proof. See discussion above. \square

We also get the cohomology long exact sequence

$$0 \rightarrow H_{\acute{e}tale}^0(X, \mathbf{G}_m) \rightarrow H_{\acute{e}tale}^0(X, j_* \mathbf{G}_{m\eta}) \rightarrow H_{\acute{e}tale}^0(X, \bigoplus i_{x*} \mathbf{Z}) \rightarrow H_{\acute{e}tale}^1(X, \mathbf{G}_m) \rightarrow 0$$

although this is the familiar

$$0 \rightarrow H_{Zar}^0(X, \mathcal{O}_X^*) \rightarrow k(X)^* \rightarrow \text{Div}(X) \rightarrow \text{Pic}(X) \rightarrow 0.$$

44.65. The Artin-Schreier sequence

Let p be a prime number. Let S be a scheme in characteristic p . The *Artin-Schreier* sequence is the short exact sequence

$$0 \rightarrow \underline{\mathbf{Z}/p\mathbf{Z}}_S \rightarrow \mathbf{G}_{a,S} \xrightarrow{F-1} \mathbf{G}_{a,S} \rightarrow 0$$

where $F - 1$ is the map $x \mapsto x^p - x$.

Lemma 44.65.1. *Let p be a prime. Let S be a scheme of characteristic p .*

- (1) *If S is affine, then $H_{\acute{e}tale}^q(S, \underline{\mathbf{Z}/p\mathbf{Z}}) = 0$ for all $q \geq 2$.*
- (2) *If S is a quasi-compact and quasi-separated scheme of dimension d , then $H_{\acute{e}tale}^q(S, \underline{\mathbf{Z}/p\mathbf{Z}}) = 0$ for all $q \geq 2 + d$.*

Proof. Recall that the étale cohomology of the structure sheaf is equal to its cohomology on the underlying topological space (Theorem 44.22.4). The first statement follows from the Artin-Schreier exact sequence and the vanishing of cohomology of the structure sheaf on an affine scheme (Cohomology of Schemes, Lemma 29.2.2). The second statement follows by the same argument from the vanishing of Cohomology, Proposition 20.23.4 and the fact that S is a spectral space (Properties, Lemma 27.2.4). \square

Lemma 44.65.2. *Let k be an algebraically closed field of characteristic $p > 0$. Let V be a finite dimensional k -vector space. Let $F : V \rightarrow V$ be a Frobenius linear map, i.e., an additive map such that $F(\lambda v) = \lambda^p F(v)$ for all $\lambda \in k$ and $v \in V$. Then $F - 1 : V \rightarrow V$ is surjective with kernel a finite dimensional \mathbf{F}_p -vector space of dimension $\leq \dim_k(V)$.*

Proof. If $F = 0$, then the statement holds. If we have a filtration of V by F -stable subvector spaces such that the statement holds for each graded piece, then it holds for (V, F) . Combining these two remarks we may assume the kernel of F is zero.

Choose a basis v_1, \dots, v_n of V and write $F(v_i) = \sum a_{ij} v_j$. Observe that $v = \sum \lambda_i v_i$ is in the kernel if and only if $\sum \lambda_i^p a_{ij} v_j = 0$. Since k is algebraically closed this implies the matrix (a_{ij}) is invertible. Let (b_{ij}) be its inverse. Then to see that $F - 1$ is surjective we pick $w = \sum \mu_i v_i \in V$ and we try to solve

$$(F - 1)\left(\sum \lambda_i v_i\right) = \sum \lambda_i^p a_{ij} v_j - \sum \lambda_j v_j = \sum \mu_j v_j$$

This is equivalent to

$$\sum \lambda_j^p v_j - \sum b_{ij} \lambda_i v_j = \sum b_{ij} \mu_i v_j$$

in other words

$$\lambda_j^p - \sum b_{ij} \lambda_i = \sum b_{ij} \mu_i, \quad j = 1, \dots, \dim(V).$$

The algebra

$$A = k[x_1, \dots, x_n]/(x_j^p - \sum b_{ij} x_i - \sum b_{ij} \mu_i)$$

is standard smooth over k (Algebra, Definition 10.132.6) because the matrix (b_{ij}) is invertible and the partial derivatives of x_j^p are zero. A basis of A over k is the set of monomials $x_1^{e_1} \dots x_n^{e_n}$ with $e_i < p$, hence $\dim_k(A) = p^n$. Since k is algebraically closed we see that $\text{Spec}(A)$ has exactly p^n points. It follows that $F - 1$ is surjective and every fibre has p^n points, i.e., the kernel of $F - 1$ is a group with p^n elements. \square

Lemma 44.65.3. *Let X be a separated scheme of finite type over a field k . Let \mathcal{F} be a coherent sheaf of \mathcal{O}_X -modules. Then $\dim_k H^d(X, \mathcal{F}) < \infty$ where $d = \dim(X)$.*

Proof. We will prove this by induction on d . The case $d = 0$ holds because in that case X is the spectrum of a finite dimensional k -algebra A (Varieties, Lemma 32.13.2) and every coherent sheaf \mathcal{F} corresponds to a finite A -module $M = H^0(X, \mathcal{F})$ which has $\dim_k M < \infty$.

Assume $d > 0$ and the result has been shown for separated schemes of finite type of dimension $< d$. The scheme X is Noetherian. Consider the property \mathcal{P} of coherent sheaves on X defined by the rule

$$\mathcal{P}(\mathcal{F}) \Leftrightarrow \dim_k H^d(X, \mathcal{F}) < \infty$$

We are going to use the result of Cohomology of Schemes, Lemma 29.12.4 to prove that \mathcal{P} holds for every coherent sheaf on X .

Let

$$0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F} \rightarrow \mathcal{F}_2 \rightarrow 0$$

be a short exact sequence of coherent sheaves on X . Consider the long exact sequence of cohomology

$$H^d(X, \mathcal{F}_1) \rightarrow H^d(X, \mathcal{F}) \rightarrow H^d(X, \mathcal{F}_2)$$

Thus if \mathcal{P} holds for \mathcal{F}_1 and \mathcal{F}_2 , then it holds for \mathcal{F} .

Let $Z \subset X$ be an integral closed subscheme. Let \mathcal{I} be a coherent sheaf of ideals on Z . To finish the proof have to show that $H^d(X, i_*\mathcal{I}) = H^d(Z, \mathcal{I})$ is finite dimensional. If $\dim(Z) < d$, then the result holds because the cohomology group will be zero (Cohomology, Proposition 20.21.6). In this way we reduce to the situation discussed in the following paragraph.

Assume X is a variety of dimension d and $\mathcal{F} = \mathcal{I}$ is a coherent ideal sheaf. In this case we have a short exact sequence

$$0 \rightarrow \mathcal{I} \rightarrow \mathcal{O}_X \rightarrow i_*\mathcal{O}_Z \rightarrow 0$$

where $i : Z \rightarrow X$ is the closed subscheme defined by \mathcal{I} . By induction hypothesis we see that $H^{d-1}(Z, \mathcal{O}_Z) = H^{d-1}(X, i_*\mathcal{O}_Z)$ is finite dimensional. Thus we see that it suffices to prove the result for the structure sheaf.

We can apply Chow's lemma (Cohomology of Schemes, Lemma 29.16.1) to the morphism $X \rightarrow \text{Spec}(k)$. Thus we get a diagram

$$\begin{array}{ccccc} X & \xleftarrow{\pi} & X' & \xrightarrow{i} & \mathbf{P}_k^n \\ & \searrow g & \downarrow g' & \swarrow & \\ & & \text{Spec}(k) & & \end{array}$$

as in the statement of Chow's lemma. Also, let $U \subset X$ be the dense open subscheme such that $\pi^{-1}(U) \rightarrow U$ is an isomorphism. We may assume X' is a variety as well, see Cohomology of Schemes, Remark 29.16.2. The morphism $i' = (i, \pi) : X' \rightarrow \mathbf{P}_X^n$ is a closed immersion (loc. cit.). Hence

$$\mathcal{L} = i'^*\mathcal{O}_{\mathbf{P}_k^n}(1) \cong (i')^*\mathcal{O}_{\mathbf{P}_X^n}(1)$$

is π -relatively ample (for example by Morphisms, Lemma 28.40.7). Hence by Cohomology of Schemes, Lemma 29.15.4 there exists an $n \geq 0$ such that $R^p\pi_*\mathcal{L}^{\otimes n} = 0$ for all $p > 0$. Set $\mathcal{G} = \pi_*\mathcal{L}^{\otimes n}$. Choose any nonzero global section s of $\mathcal{L}^{\otimes n}$. Since $\mathcal{G} = \pi_*\mathcal{L}^{\otimes n}$, the section s corresponds to section of \mathcal{G} , i.e., a map $\mathcal{O}_X \rightarrow \mathcal{G}$. Since $s|_U \neq 0$ as X' is a variety and \mathcal{L} invertible, we see that $\mathcal{O}_X|_U \rightarrow \mathcal{G}|_U$ is nonzero. As $\mathcal{G}|_U = \mathcal{K}\mathcal{L}^{\otimes n}|_{\pi^{-1}(U)}$ is invertible we conclude that we have a short exact sequence

$$0 \rightarrow \mathcal{O}_X \rightarrow \mathcal{G} \rightarrow \mathcal{Q} \rightarrow 0$$

where \mathcal{Q} is coherent and supported on a proper closed subscheme of X . Arguing as before using our induction hypothesis, we see that it suffices to prove $\dim H^d(X, \mathcal{G}) < \infty$.

By the Leray spectral sequence (Cohomology, Lemma 20.14.6) we see that $H^d(X, \mathcal{G}) = H^d(X', \mathcal{L}^{\otimes n})$. Let $\overline{X}' \subset \mathbf{P}_k^n$ be the closure of X' . Then \overline{X}' is a projective variety of dimension d over k and $X' \subset \overline{X}'$ is a dense open. The invertible sheaf \mathcal{L} is the restriction of $\mathcal{O}_{\overline{X}'}(n)$ to X . By Cohomology, Proposition 20.23.4 the map

$$H^d(\overline{X}', \mathcal{O}_{\overline{X}'}(n)) \longrightarrow H^d(X', \mathcal{L}^{\otimes n})$$

is surjective. Since the cohomology group on the left has finite dimension by Cohomology of Schemes, Lemma 29.15.1 the proof is complete. \square

Lemma 44.65.4. *Let X be separated of finite type over an algebraically closed field k of characteristic $p > 0$. Then $H_{\text{étale}}^q(X, \underline{\mathbf{Z}}/p\underline{\mathbf{Z}}) = 0$ for $q \geq \dim(X) + 1$.*

Proof. Let $d = \dim(X)$. By the vanishing established in Lemma 44.65.1 it suffices to show that $H_{\text{étale}}^{d+1}(X, \mathbf{Z}/p\mathbf{Z}) = 0$. By Lemma 44.65.3 we see that $H^d(X, \mathcal{O}_X)$ is a finite dimensional k -vector space. Hence the long exact cohomology sequence associated to the Artin-Schreier sequence ends with

$$H^d(X, \mathcal{O}_X) \xrightarrow{F-1} H^d(X, \mathcal{O}_X) \rightarrow H_{\text{étale}}^{d+1}(X, \mathbf{Z}/p\mathbf{Z}) \rightarrow 0$$

By Lemma 44.65.2 the map $F - 1$ in this sequence is surjective. This proves the lemma. \square

Lemma 44.65.5. *Let X be a proper scheme over an algebraically closed field k of characteristic $p > 0$. Then*

- (1) $H_{\text{étale}}^q(X, \mathbf{Z}/p\mathbf{Z})$ is a finite $\mathbf{Z}/p\mathbf{Z}$ -module for all q , and
- (2) $H_{\text{étale}}^q(X, \mathbf{Z}/p\mathbf{Z}) \rightarrow H_{\text{étale}}^q(X_{k'}, \mathbf{Z}/p\mathbf{Z})$ is an isomorphism if $k \subset k'$ is an extension of algebraically closed fields.

Proof. By Cohomology of Schemes, Lemma 29.17.4) and the comparison of cohomology of Theorem 44.22.4 the cohomology groups $H_{\text{étale}}^q(X, \mathbf{G}_a) = H^q(X, \mathcal{O}_X)$ are finite dimensional k -vector spaces. Hence by Lemma 44.65.2 the long exact cohomology sequence associated to the Artin-Schreier sequence, splits into short exact sequences

$$0 \rightarrow H_{\text{étale}}^q(X, \mathbf{Z}/p\mathbf{Z}) \rightarrow H^q(X, \mathcal{O}_X) \xrightarrow{F-1} H^q(X, \mathcal{O}_X) \rightarrow 0$$

and moreover the \mathbf{F}_p -dimension of the cohomology groups $H_{\text{étale}}^q(X, \mathbf{Z}/p\mathbf{Z})$ is equal to the k -dimension of the vector space $H^q(X, \mathcal{O}_X)$. This proves the first statement. The second statement follows as $H^q(X, \mathcal{O}_X) \otimes_k k' \rightarrow H^q(X_{k'}, \mathcal{O}_{X_{k'}})$ is an isomorphism by flat base change (Cohomology of Schemes, Lemma 29.5.2). \square

44.66. Picard groups of curves

Our next step is to use the Kummer sequence to deduce some information about the cohomology group of a curve with finite coefficients. In order to get vanishing in the long exact sequence, we review some facts about Picard groups.

Let X be a smooth projective curve over an algebraically closed field k . There exists a short exact sequence

$$0 \rightarrow \text{Pic}^0(X) \rightarrow \text{Pic}(X) \xrightarrow{\text{deg}} \mathbf{Z} \rightarrow 0.$$

The abelian group $\text{Pic}^0(X)$ can be identified with $\text{Pic}^0(X) = \underline{\text{Pic}}_{X/k}^0(k)$, i.e., the k -valued points of an abelian variety $\underline{\text{Pic}}_{X/k}^0$ of dimension $g = g(X)$ over k .

Definition 44.66.1. Let k be a field. An *abelian variety* is a group scheme over k which is also a proper variety over k .

Proposition 44.66.2. *Let A be an abelian variety over an algebraically closed field k . Then*

- (1) A is projective over k ;
- (2) A is a commutative group scheme;
- (3) the morphism $[n] : A \rightarrow A$ is surjective for all $n \geq 1$, in other words $A(k)$ is a divisible abelian group;
- (4) $A[n] = \text{Ker}(A \xrightarrow{[n]} A)$ is a finite flat group scheme of rank $n^{2 \dim A}$ over k . It is reduced if and only if $n \in k^*$;

(5) if $n \in k^*$ then $A(k)[n] = A[n](k) \cong (\mathbf{Z}/n\mathbf{Z})^{2 \dim(A)}$.

Proof. See Mumford’s book on abelian varieties, [Mum70]. □

Consequently, if $n \in k^*$ then $\text{Pic}^0(X)[n] \cong (\mathbf{Z}/n\mathbf{Z})^{2g}$ as abelian groups.

Lemma 44.66.3. *Let X be a smooth projective curve of genus g over an algebraically closed field k and let $n \geq 1$ be invertible in k . Then there are canonical identifications*

$$H_{\acute{e}tale}^q(X, \mu_n) = \begin{cases} \mu_n(k) & \text{if } q = 0, \\ \text{Pic}^0(X)[n] & \text{if } q = 1, \\ \mathbf{Z}/n\mathbf{Z} & \text{if } q = 2, \\ 0 & \text{if } q \geq 3. \end{cases}$$

Since $\mu_n \cong \underline{\mathbf{Z}/n\mathbf{Z}}$, this gives (noncanonical) identifications

$$H_{\acute{e}tale}^q(X, \underline{\mathbf{Z}/n\mathbf{Z}}) \cong \begin{cases} \mathbf{Z}/n\mathbf{Z} & \text{if } q = 0, \\ (\mathbf{Z}/n\mathbf{Z})^{2g} & \text{if } q = 1, \\ \mathbf{Z}/n\mathbf{Z} & \text{if } q = 2, \\ 0 & \text{if } q \geq 3. \end{cases}$$

Proof. The Kummer sequence $0 \rightarrow \mu_{n,X} \rightarrow \mathbf{G}_{m,X} \xrightarrow{(\cdot)^n} \mathbf{G}_{m,X} \rightarrow 0$ give the long exact cohomology sequence

$$\begin{array}{ccccccc} 0 & \longrightarrow & \mu_n(k) & \longrightarrow & k^* & \xrightarrow{(\cdot)^n} & k^* \\ & & & & & \swarrow & \\ & & & & & H_{\acute{e}tale}^1(X, \mu_n) & \longrightarrow & \text{Pic}(X) & \xrightarrow{(\cdot)^n} & \text{Pic}(X) \\ & & & & & \swarrow & \\ & & & & & H_{\acute{e}tale}^2(X, \mu_n) & \longrightarrow & 0 & \longrightarrow & 0 \dots \end{array}$$

The n power map $k^* \rightarrow k^*$ is surjective since k is algebraically closed. So we need to compute the kernel and cokernel of the map $\text{Pic}(X) \xrightarrow{(\cdot)^n} \text{Pic}(X)$. Consider the commutative diagram with exact rows

$$\begin{array}{ccccccc} 0 & \longrightarrow & \text{Pic}^0(X) & \longrightarrow & \text{Pic}(X) & \xrightarrow{\text{deg}} & \mathbf{Z} & \longrightarrow & 0 \\ & & \downarrow (\cdot)^n & & \downarrow (\cdot)^n & & \downarrow n & & \\ 0 & \longrightarrow & \text{Pic}^0(X) & \longrightarrow & \text{Pic}(X) & \xrightarrow{\text{deg}} & \mathbf{Z} & \longrightarrow & 0 \end{array}$$

where the left vertical map is surjective by Proposition 44.66.2 (3). Applying the snake lemma gives the desired identifications. □

Lemma 44.66.4. *Let $\pi : X \rightarrow Y$ be a nonconstant morphism of smooth projective curves over an algebraically closed field k and let $n \geq 1$ be invertible in k . The map*

$$\pi^* : H_{\acute{e}tale}^2(Y, \mu_n) \longrightarrow H_{\acute{e}tale}^2(X, \mu_n)$$

is given by multiplication by the degree of π .

Proof. Observe that the statement makes sense as we have identified both cohomology groups $H_{\acute{e}tale}^2(Y, \mu_n)$ and $H_{\acute{e}tale}^2(X, \mu_n)$ with $\mathbf{Z}/n\mathbf{Z}$ in Lemma 44.66.3. In fact, if \mathcal{L} is a line bundle of degree 1 on Y with class $[\mathcal{L}] \in H_{\acute{e}tale}^1(Y, \mathbf{G}_m)$, then the coboundary of $[\mathcal{L}]$ is the generator of $H_{\acute{e}tale}^2(Y, \mu_n)$. Here the coboundary is the coboundary of the long exact sequence of cohomology associated to the Kummer sequence. Thus the result of the lemma follows from the fact that the degree of the line bundle $\pi^*\mathcal{L}$ on X is $\deg(\pi)$. Some details omitted. \square

Lemma 44.66.5. *Let X be an affine smooth curve over an algebraically closed field k and $n \in k^*$. Then*

- (1) $H_{\acute{e}tale}^0(X, \mu_n) = \mu_n(k)$;
- (2) $H_{\acute{e}tale}^1(X, \mu_n) \cong (\mathbf{Z}/n\mathbf{Z})^{2g+r-1}$, where r is the number of points in $\bar{X} - X$ for some smooth projective compactification \bar{X} of X , and
- (3) for all $q \geq 2$, $H_{\acute{e}tale}^q(X, \mu_n) = 0$.

Proof. Write $X = \bar{X} - \{x_1, \dots, x_r\}$. Then $\text{Pic}(X) = \text{Pic}(\bar{X})/R$, where R is the subgroup generated by $\mathcal{O}_{\bar{X}}(x_i)$, $1 \leq i \leq r$. Since $r \geq 1$, we see that $\text{Pic}^0(X) \rightarrow \text{Pic}(\bar{X})$ is surjective, hence $\text{Pic}(X)$ is divisible. Applying the Kummer sequence, we get (1) and (3). For (2), recall that

$$\begin{aligned} H_{\acute{e}tale}^1(X, \mu_n) &= \{(\mathcal{L}, \alpha) \mid \mathcal{L} \in \text{Pic}(X), \alpha : \mathcal{L}^{\otimes n} \rightarrow \mathcal{O}_X\} / \cong \\ &= \{(\bar{\mathcal{L}}, D, \bar{\alpha})\} / \tilde{R} \end{aligned}$$

where $\bar{\mathcal{L}} \in \text{Pic}^0(\bar{X})$, D is a divisor on \bar{X} supported on $\{x_1, \dots, x_r\}$ and $\bar{\alpha} : \bar{\mathcal{L}}^{\otimes n} \cong \mathcal{O}_{\bar{X}}(D)$ is an isomorphism. Note that D must have degree 0. Further \tilde{R} is the subgroup of triples of the form $(\mathcal{O}_{\bar{X}}(D'), nD', 1^{\otimes n})$ where D' is supported on $\{x_1, \dots, x_r\}$ and has degree 0. Thus, we get an exact sequence

$$0 \longrightarrow H_{\acute{e}tale}^1(\bar{X}, \mu_n) \longrightarrow H_{\acute{e}tale}^1(X, \mu_n) \longrightarrow \bigoplus_{i=1}^r \mathbf{Z}/n\mathbf{Z} \xrightarrow{\Sigma} \mathbf{Z}/n\mathbf{Z} \longrightarrow 0$$

where the middle map sends the class of a triple $(\bar{\mathcal{L}}, D, \bar{\alpha})$ with $D = \sum_{i=1}^r a_i(x_i)$ to the r -tuple $(a_i)_{i=1}^r$. It now suffices to use Lemma 44.66.3 to count ranks. \square

Remark 44.66.6. The “natural” way to prove the previous corollary is to excise X from \bar{X} . This is possible, we just haven’t developed that theory.

Remark 44.66.7. Let k be an algebraically closed field. Let n be an integer prime to the characteristic of k . Recall that

$$\mathbf{G}_{m,k} = \mathbf{A}_k^1 \setminus \{0\} = \mathbf{P}_k^1 \setminus \{0, \infty\}$$

We claim there is a canonical isomorphism

$$H_{\acute{e}tale}^1(\mathbf{G}_{m,k}, \mu_n) = \mathbf{Z}/n\mathbf{Z}$$

What does this mean? This means there is an element 1_k in $H_{\acute{e}tale}^1(\mathbf{G}_{m,k}, \mu_n)$ such that for every morphism $\text{Spec}(k') \rightarrow \text{Spec}(k)$ the pullback map on étale cohomology for the map $\mathbf{G}_{m,k'} \rightarrow \mathbf{G}_{m,k}$ maps 1_k to $1_{k'}$. (In particular this element is fixed under all automorphisms of k .) To see this, consider the $\mu_{n,\mathbf{Z}}$ -torsor $\mathbf{G}_{m,\mathbf{Z}} \rightarrow \mathbf{G}_{m,\mathbf{Z}}$, $x \mapsto x^n$. By the identification of torsors with first cohomology, this pulls back to give our canonical elements 1_k . Twisting back we see that there are canonical identifications

$$H_{\acute{e}tale}^1(\mathbf{G}_{m,k}, \mathbf{Z}/n\mathbf{Z}) = \text{Hom}(\mu_n(k), \mathbf{Z}/n\mathbf{Z}),$$

i.e., these isomorphisms are compatible with respect to maps of algebraically closed fields, in particular with respect to automorphisms of k .

44.67. Extension by zero

The general material in Modules on Sites, Section 18.19 allows us to make the following definition.

Definition 44.67.1. Let $j : U \rightarrow X$ be an étale morphism of schemes.

- (1) The restriction functor $j^{-1} : Sh(X_{\acute{e}tale}) \rightarrow Sh(U_{\acute{e}tale})$ has a left adjoint $j_!^{Sh} : Sh(X_{\acute{e}tale}) \rightarrow Sh(U_{\acute{e}tale})$.
- (2) The restriction functor $j^{-1} : Ab(X_{\acute{e}tale}) \rightarrow Ab(U_{\acute{e}tale})$ has a left adjoint which is denoted $j_! : Ab(U_{\acute{e}tale}) \rightarrow Ab(X_{\acute{e}tale})$ and called *extension by zero*.
- (3) Let Λ be a ring. The restriction functor $j^{-1} : Mod(X_{\acute{e}tale}, \Lambda) \rightarrow Mod(U_{\acute{e}tale}, \Lambda)$ has a left adjoint which is denoted $j_! : Mod(U_{\acute{e}tale}, \Lambda) \rightarrow Mod(X_{\acute{e}tale}, \Lambda)$ and called *extension by zero*.

If \mathcal{F} is an abelian sheaf on $X_{\acute{e}tale}$, then $j_!\mathcal{F} \neq j_!^{Sh}\mathcal{F}$ in general. On the other hand $j_!$ for sheaves of Λ -modules agrees with $j_!$ on underlying abelian sheaves (Modules on Sites, Remark 18.19.5). The functor $j_!$ is characterized by the functorial isomorphism

$$\mathrm{Hom}_X(j_!\mathcal{F}, \mathcal{G}) = \mathrm{Hom}_U(\mathcal{F}, j^{-1}\mathcal{G})$$

for all $\mathcal{F} \in Ab(U_{\acute{e}tale})$ and $\mathcal{G} \in Ab(X_{\acute{e}tale})$. Similarly for sheaves of Λ -modules.

To describe it more explicitly, recall that j^{-1} is just the restriction via the functor $U_{\acute{e}tale} \rightarrow X_{\acute{e}tale}$. In other words, $j^{-1}\mathcal{G}(U') = \mathcal{G}(U')$ for U' étale over U . For $\mathcal{F} \in Ab(U_{\acute{e}tale})$ we consider the presheaf

$$j_!^{PSh}\mathcal{F} : X_{\acute{e}tale} \longrightarrow Ab, \quad V \longmapsto \bigoplus_{V \rightarrow U} \mathcal{F}(V)$$

Then $j_!\mathcal{F}$ is the sheafification of $j_!^{PSh}\mathcal{F}$.

Exercise 44.67.2. Prove directly that $j_!$ is left adjoint to j^{-1} and that j_* is right adjoint to j^{-1} .

Proposition 44.67.3. Let $j : U \rightarrow X$ be an étale morphism of schemes. Let \mathcal{F} in $Ab(U_{\acute{e}tale})$. If $\bar{x} : \mathrm{Spec}(k) \rightarrow X$ is a geometric point of X , then

$$(j_!\mathcal{F})_{\bar{x}} = \bigoplus_{\bar{u} : \mathrm{Spec}(k) \rightarrow U, f(\bar{u}) = \bar{x}} \mathcal{F}_{\bar{u}}.$$

In particular, $j_!$ is an exact functor.

Proof. Exactness of $j_!$ is very general, see Modules on Sites, Lemma 18.19.3. Of course it does also follow from the description of stalks. The formula for the stalk of $j_!\mathcal{F}$ can be deduced directly from the explicit description of $j_!$ given above. On the other hand, we can deduce it from the very general Modules on Sites, Lemma 18.37.1 and the description of points of the small étale site in terms of geometric points, see Lemma 44.29.12. \square

Lemma 44.67.4 (Extension by zero commutes with base change). Let $f : Y \rightarrow X$ be a morphism of schemes. Let $j : V \rightarrow X$ be an étale morphism. Consider the

fibre product

$$\begin{array}{ccc}
 V' = Y \times_X V & \longrightarrow & Y \\
 f' \downarrow & & \downarrow f \\
 V & \xrightarrow{j} & X
 \end{array}$$

Then we have $j'_! f'^{-1} = f^{-1} j_!$ on abelian sheaves and on sheaves of modules.

Proof. This is true because $j'_! f'^{-1}$ is left adjoint to $f'_*(j')^{-1}$ and $f^{-1} j_!$ is left adjoint to $j^{-1} f_*$. Further $f'_*(j')^{-1} = j^{-1} f_*$ because f_* commutes with étale localization (by construction). In fact, the lemma holds very generally in the setting of a morphism of sites, see Modules on Sites, Lemma 18.20.1. \square

Lemma 44.67.5. *Let $j : U \rightarrow X$ be finite and étale. Then $j_! = j_*$ on abelian sheaves and sheaves of Λ -modules.*

Proof. We prove this in the case of abelian sheaves. By Modules on Sites, Remark 18.19.7 there is a natural transformation $j_! \rightarrow j_*$. It suffices to check this is an isomorphism étale locally on X . Thus we may assume $U \rightarrow X$ is a finite disjoint union of isomorphisms, see Étale Morphisms, Lemma 40.18.3. We omit the proof in this case. \square

Lemma 44.67.6. *Let X be a scheme. Let $Z \subset X$ be a closed subscheme and let $U \subset X$ be the complement. Denote $i : Z \rightarrow X$ and $j : U \rightarrow X$ the inclusion morphisms. For every abelian sheaf on $X_{\text{étale}}$ there is a canonical short exact sequence*

$$0 \rightarrow j_! j^{-1} \mathcal{F} \rightarrow \mathcal{F} \rightarrow i_* i^{-1} \mathcal{F} \rightarrow 0$$

on $X_{\text{étale}}$.

Proof. We obtain the maps by the adjointness properties of the functors involved. For a geometric point \bar{x} in X we have either $\bar{x} \in U$ in which case the map on the left hand side is an isomorphism on stalks and the stalk of $i_* i^{-1} \mathcal{F}$ is zero or $\bar{x} \in Z$ in which case the map on the right hand side is an isomorphism on stalks and the stalk of $j_! j^{-1} \mathcal{F}$ is zero. Here we have used the description of stalks of Lemma 44.47.3 and Proposition 44.67.3. \square

44.68. Locally constant sheaves

This section is the analogue of Modules on Sites, Section 18.42 for the étale site.

Definition 44.68.1. Let X be a scheme. Let \mathcal{F} be a sheaf of sets on $X_{\text{étale}}$.

- (1) Let E be a set. We say \mathcal{F} is the *constant sheaf with value E* if \mathcal{F} is the sheafification of the presheaf $U \mapsto E$. Notation: \underline{E}_X or \underline{E} .
- (2) We say \mathcal{F} is a *constant sheaf* if it is isomorphic to a sheaf as in (1).
- (3) We say \mathcal{F} is *locally constant* if there exists a covering $\{U_i \rightarrow X\}$ such that $\mathcal{F}|_{U_i}$ is a constant sheaf.
- (4) We say that \mathcal{F} is *finite locally constant* if it is locally constant and the values are finite sets.

Let \mathcal{F} be a sheaf of abelian groups on $X_{\text{étale}}$.

- (1) Let A be an abelian group. We say \mathcal{F} is the *constant sheaf with value A* if \mathcal{F} is the sheafification of the presheaf $U \mapsto A$. Notation: \underline{A}_X or \underline{A} .

- (2) We say \mathcal{F} is a *constant sheaf* if it is isomorphic as an abelian sheaf to a sheaf as in (1).
- (3) We say \mathcal{F} is *locally constant* if there exists a covering $\{U_i \rightarrow X\}$ such that $\mathcal{F}|_{U_i}$ is a constant sheaf.
- (4) We say that \mathcal{F} is *finite locally constant* if it is locally constant and the values are finite abelian groups.

Let Λ be a ring. Let \mathcal{F} be a sheaf of Λ -modules on $X_{\acute{e}tale}$.

- (1) Let M be a Λ -module. We say \mathcal{F} is the *constant sheaf with value M* if \mathcal{F} is the sheafification of the presheaf $U \mapsto M$. Notation: \underline{M}_X or \underline{M} .
- (2) We say \mathcal{F} is a *constant sheaf* if it is isomorphic as a sheaf of Λ -modules to a sheaf as in (1).
- (3) We say \mathcal{F} is *locally constant* if there exists a covering $\{U_i \rightarrow X\}$ such that $\mathcal{F}|_{U_i}$ is a constant sheaf.

Lemma 44.68.2. *Let $f : X \rightarrow Y$ be a morphism of schemes. If \mathcal{G} is a locally constant sheaf of sets, abelian groups, or Λ -modules on $Y_{\acute{e}tale}$, the same is true for $f^{-1}\mathcal{G}$ on $X_{\acute{e}tale}$.*

Proof. Holds for any morphism of topoi, see Modules on Sites, Lemma 18.42.2. \square

Lemma 44.68.3. *Let $f : X \rightarrow Y$ be a finite étale morphism of schemes. If \mathcal{F} is a (finite) locally constant sheaf of sets, (finite) locally constant sheaf of abelian groups, or (finite type) locally constant sheaf of Λ -modules on $X_{\acute{e}tale}$, the same is true for $f_*\mathcal{F}$ on $Y_{\acute{e}tale}$.*

Proof. The construction of f_* commutes with étale localization. A finite étale morphism is locally isomorphic to a disjoint union of isomorphisms, see Étale Morphisms, Lemma 40.18.3. Thus the lemma says that if \mathcal{F}_i , $i = 1, \dots, n$ are (finite) locally constant sheaves of sets, then $\prod_{i=1, \dots, n} \mathcal{F}_i$ is too. This is clear. Similarly for sheaves of abelian groups and modules. \square

Lemma 44.68.4. *Let X be a scheme and \mathcal{F} a sheaf of sets on $X_{\acute{e}tale}$. Then the following are equivalent*

- (1) \mathcal{F} is finite locally constant, and
- (2) $\mathcal{F} = h_U$ for some finite étale morphism $U \rightarrow X$.

Proof. A finite étale morphism is locally isomorphic to a disjoint union of isomorphisms, see Étale Morphisms, Lemma 40.18.3. Thus (2) implies (1). Conversely, if \mathcal{F} is finite locally constant, then there exists an étale covering $\{X_i \rightarrow X\}$ such that $\mathcal{F}|_{X_i}$ is representable by $U_i \rightarrow X_i$ finite étale. Arguing exactly as in the proof of Descent, Lemma 34.35.1 we obtain a descent datum for schemes (U_i, φ_{ij}) relative to $\{X_i \rightarrow X\}$ (details omitted). This descent datum is effective for example by Descent, Lemma 34.33.1 and the resulting morphism of schemes $U \rightarrow X$ is finite étale by Descent, Lemmas 34.19.21 and 34.19.27. \square

Lemma 44.68.5. *Let X be a scheme.*

- (1) *Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a map of locally constant sheaves of sets on $X_{\acute{e}tale}$. If \mathcal{F} is finite locally constant, there exists an étale covering $\{U_i \rightarrow X\}$ such that $\varphi|_{U_i}$ is the map of constant sheaves associated to a map of sets.*
- (2) *Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a map of locally constant sheaves of abelian groups on $X_{\acute{e}tale}$. If \mathcal{F} is finite locally constant, there exists an étale covering*

$\{U_i \rightarrow X\}$ such that $\varphi|_{U_i}$ is the map of constant abelian sheaves associated to a map of abelian groups.

- (3) Let Λ be a ring. Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a map of locally constant sheaves of Λ -modules on $X_{\text{étale}}$. If \mathcal{F} is of finite type, then there exists an étale covering $\{U_i \rightarrow X\}$ such that $\varphi|_{U_i}$ is the map of constant sheaves of Λ -modules associated to a map of Λ -modules.

Proof. This holds on any site, see Modules on Sites, Lemma 18.42.3. \square

Lemma 44.68.6. Let X be a scheme.

- (1) The category of finite locally constant sheaves of sets is closed under finite limits and colimits inside $\text{Sh}(X_{\text{étale}})$.
- (2) The category of finite locally constant abelian sheaves is a weak Serre subcategory of $\text{Ab}(X_{\text{étale}})$.
- (3) Let Λ be a Noetherian ring. The category of finite type, locally constant sheaves of Λ -modules on $X_{\text{étale}}$ is a weak Serre subcategory of $\text{Mod}(X_{\text{étale}}, \Lambda)$.

Proof. This holds on any site, see Modules on Sites, Lemma 18.42.5. \square

Lemma 44.68.7. Let X be a scheme. Let Λ be a ring. The tensor product of two locally constant sheaves of Λ -modules on $X_{\text{étale}}$ is a locally constant sheaf of Λ -modules.

Proof. This holds on any site, see Modules on Sites, Lemma 18.42.6. \square

Lemma 44.68.8. Let X be a connected scheme. Let Λ be a ring and let \mathcal{F} be a locally constant sheaf of Λ -modules. Then there exists a Λ -module M and an étale covering $\{U_i \rightarrow X\}$ such that $\mathcal{F}|_{U_i} \cong \underline{M}|_{U_i}$.

Proof. Choose an étale covering $\{U_i \rightarrow X\}$ such that $\mathcal{F}|_{U_i}$ is constant, say $\mathcal{F}|_{U_i} \cong \underline{M}_i|_{U_i}$. Observe that $U_i \times_X U_j$ is empty if M_i is not isomorphic to M_j . For each Λ -module M let $I_M = \{i \in I \mid M_i \cong M\}$. As étale morphisms are open we see that $U_M = \bigcup_{i \in I_M} \text{Im}(U_i \rightarrow X)$ is an open subset of X . Then $X = \coprod U_M$ is a disjoint open covering of X . As X is connected only one U_M is nonempty and the lemma follows. \square

44.69. Constructible sheaves

Let X be a scheme. A *constructible locally closed subscheme* of X is a locally closed subscheme $T \subset X$ such that the underlying topological space of T is a constructible subset of X . If $T, T' \subset X$ are locally closed subschemes with the same underlying topological space, then $T_{\text{étale}} \cong T'_{\text{étale}}$ by the topological invariance of the étale site (Theorem 44.46.1). Thus in the following definition we may assume locally closed subschemes are reduced.

Definition 44.69.1. Let X be a scheme.

- (1) A sheaf of sets on $X_{\text{étale}}$ is *constructible* if for every affine open $U \subset X$ there exists a finite decomposition of U into constructible locally closed subschemes $U = \coprod_i U_i$ such that $\mathcal{F}|_{U_i}$ is finite locally constant for all i .
- (2) A sheaf of abelian groups on $X_{\text{étale}}$ is *constructible* if for every affine open $U \subset X$ there exists a finite decomposition of U into constructible locally closed subschemes $U = \coprod_i U_i$ such that $\mathcal{F}|_{U_i}$ is finite locally constant for all i .

- (3) Let Λ be a Noetherian ring. A sheaf of Λ -modules on $X_{\acute{e}tale}$ is *constructible* if for every affine open $U \subset X$ there exists a finite decomposition of U into constructible locally closed subschemes $U = \coprod_i U_i$ such that $\mathcal{F}|_{U_i}$ is of finite type and locally constant for all i .

It seems that this is the accepted definition. An alternative, which lends itself more readily to generalizations beyond the étale site of a scheme, would have been to define constructible sheaves by starting with h_U , $j_{U!}\mathbf{Z}/n\mathbf{Z}$, and $j_{U!}\underline{\Lambda}$ where U runs over all quasi-compact and quasi-separated objects of $X_{\acute{e}tale}$, and then take the smallest full subcategory of $Sh(X_{\acute{e}tale})$, $Ab(X_{\acute{e}tale})$, and $Mod(X_{\acute{e}tale}, \underline{\Lambda})$ containing these and closed under finite limits and colimits. It follows from Lemma 44.69.6 and Lemmas 44.71.5, 44.71.7, and 44.71.6 that this produces the same category if X is quasi-compact and quasi-separated. In general this does not produce the same category however.

A disjoint union decomposition $U = \coprod U_i$ of a scheme by locally closed subschemes will be called a *partition* of U (compare with Topology, Section 5.27).

Lemma 44.69.2. *Let X be a quasi-compact and quasi-separated scheme. Let \mathcal{F} be a sheaf of sets on $X_{\acute{e}tale}$. The following are equivalent*

- (1) \mathcal{F} is constructible,
- (2) there exists an open covering $X = \bigcup U_i$ such that $\mathcal{F}|_{U_i}$ is constructible, and
- (3) there exists a partition $X = \bigcup X_i$ by constructible locally closed subschemes such that $\mathcal{F}|_{X_i}$ is finite locally constant.

A similar statement holds for abelian sheaves and sheaves of Λ -modules if Λ is Noetherian.

Proof. It is clear that (1) implies (2).

Assume (2). For every $x \in X$ we can find an i and an affine open neighbourhood $V_x \subset U_i$ of x . Hence we can find a finite affine open covering $X = \bigcup V_j$ such that for each j there exists a finite decomposition $V_j = \coprod V_{j,k}$ by locally closed constructible subsets such that $\mathcal{F}|_{V_{j,k}}$ is finite locally constant. By Topology, Lemma 5.14.5 each $V_{j,k}$ is constructible as a subset of X . By Topology, Lemma 5.27.6 we can find a finite stratification $X = \coprod X_l$ with constructible locally closed strata such that each $V_{j,k}$ is a union of X_l . Thus (3) holds.

Assume (3) holds. Let $U \subset X$ be an affine open. Then $U \cap X_i$ is a constructible locally closed subset of U (for example by Properties, Lemma 27.2.1) and $U = \coprod U \cap X_i$ is a partition of U as in Definition 44.69.1. Thus (1) holds. \square

Lemma 44.69.3. *Let X be a quasi-compact and quasi-separated scheme. Let \mathcal{F} be a sheaf of sets, abelian groups, Λ -modules (with Λ Noetherian) on $X_{\acute{e}tale}$. If there exist constructible locally closed subschemes $T_i \subset X$ such that (a) $X = \bigcup T_j$ and (b) $\mathcal{F}|_{T_j}$ is constructible, then \mathcal{F} is constructible.*

Proof. First, we can assume the covering is finite as X is quasi-compact in the spectral topology (Topology, Lemma 5.22.2 and Properties, Lemma 27.2.4). Observe that each T_i is a quasi-compact and quasi-separated scheme in its own right (because it is constructible in X ; details omitted). Thus we can find a finite partition $T_i = \coprod T_{i,j}$ into locally closed constructible parts of T_i such that $\mathcal{F}|_{T_{i,j}}$ is finite locally constant (Lemma 44.69.2). By Topology, Lemma 5.14.12 we see that

$T_{i,j}$ is a constructible locally closed subscheme of X . Then we can apply Topology, Lemma 5.27.6 to $X = \bigcup T_{i,j}$ to find the desired partition of X . \square

Lemma 44.69.4. *Let X be a scheme. Checking constructibility of a sheaf of sets, abelian groups, Λ -modules (with Λ Noetherian) can be done Zariski locally on X .*

Proof. The statement means if $X = \bigcup U_i$ is an open covering such that $\mathcal{F}|_{U_i}$ is constructible, then \mathcal{F} is constructible. If $U \subset X$ is affine open, then $U = \bigcup U \cap U_i$ and $\mathcal{F}|_{U \cap U_i}$ is constructible (it is trivial that the restriction of a constructible sheaf to an open is constructible). It follows from Lemma 44.69.2 that $\mathcal{F}|_U$ is constructible, i.e., a suitable partition of U exists. \square

Lemma 44.69.5. *Let $f : X \rightarrow Y$ be a morphism of schemes. If \mathcal{F} is a constructible sheaf of sets, abelian groups, or Λ -modules (with Λ Noetherian) on $Y_{\text{étale}}$, the same is true for $f^{-1}\mathcal{F}$ on $X_{\text{étale}}$.*

Proof. By Lemma 44.69.4 this reduces to the case where X and Y are affine. By Lemma 44.69.2 it suffices to find a finite partition of X by constructible locally closed subschemes such that $f^{-1}\mathcal{F}$ is finite locally constant on each of them. To find it we just pull back the partition of Y adapted to \mathcal{F} and use Lemma 44.68.2. \square

Lemma 44.69.6. *Let X be a scheme.*

- (1) *The category of constructible sheaves of sets is closed under finite limits and colimits inside $\text{Sh}(X_{\text{étale}})$.*
- (2) *The category of constructible abelian sheaves is a weak Serre subcategory of $\text{Ab}(X_{\text{étale}})$.*
- (3) *Let Λ be a Noetherian ring. The category of constructible sheaves of Λ -modules on $X_{\text{étale}}$ is a weak Serre subcategory of $\text{Mod}(X_{\text{étale}}, \Lambda)$.*

Proof. We prove (3). We will use the criterion of Homology, Lemma 12.9.3. Suppose that $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ is a map of constructible sheaves of Λ -modules. We have to show that $\mathcal{K} = \text{Ker}(\varphi)$ and $\mathcal{Q} = \text{Coker}(\varphi)$ are constructible. Similarly, suppose that $0 \rightarrow \mathcal{F} \rightarrow \mathcal{E} \rightarrow \mathcal{G} \rightarrow 0$ is a short exact sequence of sheaves of Λ -modules with \mathcal{F}, \mathcal{G} constructible. We have to show that \mathcal{E} is constructible. In both cases we can replace X with the members of an affine open covering. Hence we may assume X is affine. Then we may further replace X by the members of a finite partition of X by constructible locally closed subschemes on which \mathcal{F} and \mathcal{G} are of finite type and locally constant. Thus we may apply Lemma 44.68.6 to conclude.

The proofs of (1) and (2) are very similar and are omitted. \square

Lemma 44.69.7. *Let X be a scheme. Let Λ be a Noetherian ring. The tensor product of two constructible sheaves of Λ -modules on $X_{\text{étale}}$ is a constructible sheaf of Λ -modules.*

Proof. The question immediately reduces to the case where X is affine. Since any two partitions of X with constructible locally closed strata have a common refinement of the same type and since pullbacks commute with tensor product we reduce to Lemma 44.68.7. \square

Lemma 44.69.8. *Let X be a quasi-compact and quasi-separated scheme.*

- (1) *Let $\mathcal{F} \rightarrow \mathcal{G}$ be a map of constructible sheaves of sets on $X_{\text{étale}}$. Then the set of points $x \in X$ where $\mathcal{F}_{\bar{x}} \rightarrow \mathcal{G}_{\bar{x}}$ is surjective, resp. injective, resp. is isomorphic to a given map of sets, is constructible in X .*

- (2) Let \mathcal{F} be a constructible abelian sheaf on $X_{\text{étale}}$. The support of \mathcal{F} is constructible.
- (3) Let Λ be a Noetherian ring. Let \mathcal{F} be a constructible sheaf of Λ -modules on $X_{\text{étale}}$. The support of \mathcal{F} is constructible.

Proof. Proof of (1). Let $X = \coprod X_i$ be a partition of X by locally closed constructible subschemes such that both \mathcal{F} and \mathcal{G} are finite locally constant over the parts (use Lemma 44.69.2 for both \mathcal{F} and \mathcal{G} and choose a common refinement). Then apply Lemma 44.68.5 to the restriction of the map to each part.

The proof of (2) and (3) is omitted. \square

The following lemma will turn out to be very useful later on. It roughly says that the category of constructible sheaves has a kind of weak “Noetherian” property.

Lemma 44.69.9. *Let X be a quasi-compact and quasi-separated scheme. Let $\mathcal{F} = \text{colim}_{i \in I} \mathcal{F}_i$ be a filtered colimit of sheaves of sets, abelian sheaves, or sheaves of modules.*

- (1) *If \mathcal{F} and \mathcal{F}_i are constructible sheaves of sets, then the ind-object \mathcal{F}_i is essentially constant with value \mathcal{F} .*
- (2) *If \mathcal{F} and \mathcal{F}_i are constructible sheaves of abelian groups, then the ind-object \mathcal{F}_i is essentially constant with value \mathcal{F} .*
- (3) *Let Λ be a Noetherian ring. If \mathcal{F} and \mathcal{F}_i are constructible sheaves of Λ -modules, then the ind-object \mathcal{F}_i is essentially constant with value \mathcal{F} .*

Proof. Proof of (1). We will use without further mention that finite limits and colimits of constructible sheaves are constructible (Lemma 44.68.6). For each i let $T_i \subset X$ be the set of points $x \in X$ where $\mathcal{F}_{i,\bar{x}} \rightarrow \mathcal{F}_{\bar{x}}$ is not surjective. Because \mathcal{F}_i and \mathcal{F} are constructible T_i is a constructible subset of X (Lemma 44.69.8). Since the stalks of \mathcal{F} are finite and since $\mathcal{F} = \text{colim}_{i \in I} \mathcal{F}_i$ we see that for all $x \in X$ we have $x \notin T_i$ for i large enough. Since X is a spectral space by Properties, Lemma 27.2.4 the constructible topology on X is quasi-compact by Topology, Lemma 5.22.2. Thus $T_i = \emptyset$ for i large enough. Thus $\mathcal{F}_i \rightarrow \mathcal{F}$ is surjective for i large enough. Assume now that $\mathcal{F}_i \rightarrow \mathcal{F}$ is surjective for all i . Choose $i \in I$. For $i' \geq i$ denote $S_{i'} \subset X$ the set of points x such that the number of elements in $\text{Im}(\mathcal{F}_{i,\bar{x}} \rightarrow \mathcal{F}_{\bar{x}})$ is equal to the number of elements in $\text{Im}(\mathcal{F}_{i,\bar{x}} \rightarrow \mathcal{F}_{i',\bar{x}})$. Because $\mathcal{F}_i, \mathcal{F}_{i'}$ and \mathcal{F} are constructible $S_{i'}$ is a constructible subset of X (details omitted; hint: use Lemma 44.69.8). Since the stalks of \mathcal{F}_i and \mathcal{F} are finite and since $\mathcal{F} = \text{colim}_{i' \geq i} \mathcal{F}_{i'}$ we see that for all $x \in X$ we have $x \notin S_{i'}$ for i' large enough. By the same argument as above we can find a large i' such that $S_{i'} = \emptyset$. Thus $\mathcal{F}_i \rightarrow \mathcal{F}_{i'}$ factors through \mathcal{F} as desired.

Proof of (2). Observe that a constructible abelian sheaf is a constructible sheaf of sets. Thus case (2) follows from (1).

Proof of (3). We will use without further mention that the category of constructible sheaves of Λ -modules is abelian (Lemma 44.68.6). For each i let Q_i be the cokernel of the map $\mathcal{F}_i \rightarrow \mathcal{F}$. The support T_i of Q_i is a constructible subset of X as Q_i is constructible (Lemma 44.69.8). Since the stalks of \mathcal{F} are finite Λ -modules and since $\mathcal{F} = \text{colim}_{i \in I} \mathcal{F}_i$ we see that for all $x \in X$ we have $x \notin T_i$ for i large enough. Since X is a spectral space by Properties, Lemma 27.2.4 the constructible topology on X is quasi-compact by Topology, Lemma 5.22.2. Thus $T_i = \emptyset$ for i large enough. This proves the first assertion. For the second, assume now that $\mathcal{F}_i \rightarrow \mathcal{F}$ is surjective

for all i . Choose $i \in I$. For $i' \geq i$ denote $\mathcal{K}_{i'}$ the image of $\text{Ker}(\mathcal{F}_i \rightarrow \mathcal{F})$ in $\mathcal{F}_{i'}$. The support $S_{i'}$ of $\mathcal{K}_{i'}$ is a constructible subset of X as $\mathcal{K}_{i'}$ is constructible. Since the stalks of $\text{Ker}(\mathcal{F}_i \rightarrow \mathcal{F})$ are finite Λ -modules and since $\mathcal{F} = \text{colim}_{i' \geq i} \mathcal{F}_{i'}$ we see that for all $x \in X$ we have $x \notin S_{i'}$ for i' large enough. By the same argument as above we can find a large i' such that $S_{i'} = \emptyset$. Thus $\mathcal{F}_i \rightarrow \mathcal{F}_{i'}$ factors through \mathcal{F} as desired. \square

44.70. Auxiliary lemmas on morphisms

Some lemmas that are useful for proving functoriality properties of constructible sheaves.

Lemma 44.70.1. *Let $U \rightarrow X$ be an étale morphism of quasi-compact and quasi-separated schemes (for example an étale morphism of Noetherian schemes). Then there exists a partition $X = \coprod_i X_i$ by constructible locally closed subschemes such that $X_i \times_X U \rightarrow X_i$ is finite étale for all i .*

Proof. If $U \rightarrow X$ is separated, then this is More on Morphisms, Lemma 36.31.10. In general, we may assume X is affine. Choose a finite affine open covering $U = \bigcup U_j$. Apply the previous case to all the morphisms $U_j \rightarrow X$ and $U_j \cap U_{j'} \rightarrow X$ and choose a common refinement $X = \coprod X_i$ of the resulting partitions. After refining the partition further we may assume X_i affine as well. Fix i and set $V = U \times_X X_i$. The morphisms $V_j = U_j \times_X X_i \rightarrow X_i$ and $V_{jj'} = (U_j \cap U_{j'}) \times_X X_i \rightarrow X_i$ are finite étale. Hence V_j and $V_{jj'}$ are affine schemes and $V_{jj'} \subset V_j$ is closed as well as open (since $V_{jj'} \rightarrow X_i$ is proper, so Morphisms, Lemma 28.42.7 applies). Then $V = \bigcup V_j$ is separated because $\mathcal{O}(V_j) \rightarrow \mathcal{O}(V_{jj'})$ is surjective, see Schemes, Lemma 25.21.8. Thus the previous case applies to $V \rightarrow X_i$ and we can further refine the partition if needed (it actually isn't but we don't need this). \square

In the Noetherian case one can prove the preceding lemma by Noetherian induction and the following amusing lemma.

Lemma 44.70.2. *Let $f : X \rightarrow Y$ be a morphism of schemes which is quasi-compact, quasi-separated, and locally of finite type. If η is a generic point of an irreducible component of Y such that $f^{-1}(\eta)$ is finite, then there exists an open $V \subset Y$ containing η such that $f^{-1}(V) \rightarrow V$ is finite.*

Proof. This is Morphisms, Lemma 28.47.1. \square

The statement of the following lemma can be strengthened a bit.

Lemma 44.70.3. *Let $f : Y \rightarrow X$ be a quasi-finite and finitely presented morphism of affine schemes.*

- (1) *There exists a surjective morphism of affine schemes $X' \rightarrow X$ and a closed subscheme $Z' \subset Y' = X' \times_X Y$ such that*
 - (a) *$Z' \subset Y'$ is a thickening, and*
 - (b) *$Z' \rightarrow X'$ is a finite étale morphism.*
- (2) *There exists a finite partition $X = \coprod X_i$ by locally closed, constructible, affine strata, and surjective finite locally free morphisms $X'_i \rightarrow X_i$ such that the reduction of $Y'_i = X'_i \times_X Y \rightarrow X'_i$ is isomorphic to $\coprod_{j=1}^{n_i} (X'_i)_{\text{red}} \rightarrow (X'_i)_{\text{red}}$ for some n_i .*

Proof. Setting $X' = \coprod X'_i$ we see that (2) implies (1). Write $X = \text{Spec}(A)$ and $Y = \text{Spec}(B)$. Write A as a filtered colimit of finite type \mathbf{Z} -algebras A_i . Since B is an A -algebra of finite presentation, we see that there exists $0 \in I$ and a finite type ring map $A_0 \rightarrow B_0$ such that $B = \text{colim } B_i$ with $B_i = A_i \otimes_{A_0} B_0$, see Algebra, Lemma 10.123.6. For i sufficiently large we see that $A_i \rightarrow B_i$ is quasi-finite, see Limits, Lemma 31.14.2. Thus we reduce to the case of finite type algebras over \mathbf{Z} , in particular we reduce to the Noetherian case. (Details omitted.)

Assume X and Y Noetherian. In this case any locally closed subset of X is constructible. By Lemma 44.70.2 and Noetherian induction we see that there is a finite partition $X = \coprod X_i$ of X by locally closed strata such that $Y \times_X X_i \rightarrow X_i$ is finite. We can refine this partition to get affine strata. Thus after replacing X by $X' = \coprod X_i$ we may assume $Y \rightarrow X$ is finite.

Assume X and Y Noetherian and $Y \rightarrow X$ finite. Suppose that we can prove (2) after base change by a surjective, flat, quasi-finite morphism $U \rightarrow X$. Thus we have a partition $U = \coprod U_i$ and finite locally free morphisms $U'_i \rightarrow U_i$ such that $U'_i \times_X Y \rightarrow U'_i$ is isomorphic to $\coprod_{j=1}^{n_i} (U'_i)_{\text{red}} \rightarrow (U'_i)_{\text{red}}$ for some n_i . Then, by the argument in the previous paragraph, we can find a partition $X = \coprod X_j$ with locally closed affine strata such that $X_j \times_X U_i \rightarrow X_j$ is finite for all i, j . By Morphisms, Lemma 28.46.2 each $X_j \times_X U_i \rightarrow X_j$ is finite locally free. Hence $X_j \times_X U'_i \rightarrow X_j$ is finite locally free (Morphisms, Lemma 28.46.3). It follows that $X = \coprod X_j$ and $X'_j = \coprod_i X_j \times_X U'_i$ is a solution for $Y \rightarrow X$. Thus it suffices to prove the result (in the Noetherian case) after a surjective flat quasi-finite base change.

Applying Morphisms, Lemma 28.46.6 we see we may assume that Y is a closed subscheme of an affine scheme Z which is (set theoretically) a finite union $Z = \bigcup_{i \in I} Z_i$ of closed subschemes mapping isomorphically to X . In this case we will find a finite partition of $X = \coprod X_j$ with affine locally closed strata that works (in other words $X'_j = X_j$). Set $T_i = Y \cap Z_i$. This is a closed subscheme of X . As X is Noetherian we can find a finite partition of $X = \coprod X_j$ by affine locally closed subschemes, such that each $X_j \times_X T_i$ is (set theoretically) a union of strata $X_j \times_X Z_i$. Replacing X by X_j we see that we may assume $I = I_1 \amalg I_2$ with $Z_i \subset Y$ for $i \in I_1$ and $Z_i \cap Y = \emptyset$ for $i \in I_2$. Replacing Z by $\bigcup_{i \in I_1} Z_i$ we see that we may assume $Y = Z$. Finally, we can replace X again by the members of a partition as above such that for every $i, i' \in I$ the intersection $Z_i \cap Z_{i'}$ is either empty or (set theoretically) equal to Z_i and $Z_{i'}$. This clearly means that Y is (set theoretically) equal to a disjoint union of the Z_i which is what we wanted to show. \square

44.71. More on constructible sheaves

Let Λ be a Noetherian ring. Let X be a scheme. We often consider $X_{\text{étale}}$ as a ringed site with sheaf of rings $\underline{\Lambda}$. In case of abelian sheaves we often take $\Lambda = \mathbf{Z}/n\mathbf{Z}$ for a suitable integer n .

Lemma 44.71.1. *Let $j : U \rightarrow X$ be an étale morphism of quasi-compact and quasi-separated schemes.*

- (1) *The sheaf h_U is a constructible sheaf of sets.*
- (2) *The sheaf $j_! \underline{M}$ is a constructible abelian sheaf for a finite abelian group M .*

- (3) If Λ is a Noetherian ring and M is a finite Λ -module, then $j_!M$ is a constructible sheaf of Λ -modules on $X_{\text{étale}}$.

Proof. By Lemma 44.70.1 there is a partition $\coprod_i X_i$ such that $\pi_i : j^{-1}(X_i) \rightarrow X_i$ is finite étale. The restriction of h_U to X_i is $h_{j^{-1}(X_i)}$ which is finite locally constant by Lemma 44.68.4. For cases (2) and (3) we note that

$$j_!(\underline{M})|_{X_i} = \pi_{i!}(\underline{M}) = \pi_{i*}(\underline{M})$$

by Lemmas 44.67.4 and 44.67.5. Thus it suffices to show the lemma for $\pi : Y \rightarrow X$ finite étale. This is Lemma 44.68.3. \square

Lemma 44.71.2. *Let X be a quasi-compact and quasi-separated scheme.*

- (1) *Let \mathcal{F} be a sheaf of sets on $X_{\text{étale}}$. Then \mathcal{F} is a filtered colimit of constructible sheaves of sets.*
- (2) *Let \mathcal{F} be a torsion abelian sheaf on $X_{\text{étale}}$. Then \mathcal{F} is a filtered colimit of constructible abelian sheaves.*
- (3) *Let Λ be a Noetherian ring and \mathcal{F} a sheaf of Λ -modules on $X_{\text{étale}}$. Then \mathcal{F} is a filtered colimit of constructible sheaves of Λ -modules.*

Proof. Let \mathcal{B} be the collection of quasi-compact and quasi-separated objects of $X_{\text{étale}}$. By Modules on Sites, Lemma 18.29.6 any sheaf of sets is a filtered colimit of sheaves of the form

$$\text{Coequalizer} \left(\coprod_{j=1, \dots, m} h_{V_j} \rightrightarrows \coprod_{i=1, \dots, n} j_{U_i} \right)$$

with V_j and U_i quasi-compact and quasi-separated objects of $X_{\text{étale}}$. By Lemmas 44.71.1 and 44.69.6 these coequalizers are constructible. This proves (1).

Let Λ be a Noetherian ring. By Modules on Sites, Lemma 18.29.6 Λ -modules \mathcal{F} is a filtered colimit of modules of the form

$$\text{Coker} \left(\bigoplus_{j=1, \dots, m} j_{V_j!} \Delta_{V_j} \rightarrow \bigoplus_{i=1, \dots, n} j_{U_i!} \Delta_{U_i} \right)$$

with V_j and U_i quasi-compact and quasi-separated objects of $X_{\text{étale}}$. By Lemmas 44.71.1 and 44.69.6 these cokernels are constructible. This proves (3).

Proof of (2). First write $\mathcal{F} = \bigcup \mathcal{F}[n]$ where $\mathcal{F}[n]$ is the n -torsion subsheaf. Then we can view $\mathcal{F}[n]$ as a sheaf of $\mathbf{Z}/n\mathbf{Z}$ -modules and apply (3). \square

Lemma 44.71.3. *Let $f : X \rightarrow Y$ be a surjective morphism of quasi-compact and quasi-separated schemes.*

- (1) *Let \mathcal{F} be a sheaf of sets on $Y_{\text{étale}}$. Then \mathcal{F} is constructible if and only if $f^{-1}\mathcal{F}$ is constructible.*
- (2) *Let \mathcal{F} be an abelian sheaf on $Y_{\text{étale}}$. Then \mathcal{F} is constructible if and only if $f^{-1}\mathcal{F}$ is constructible.*
- (3) *Let Λ be a Noetherian ring. Let \mathcal{F} be sheaf of Λ -modules on $Y_{\text{étale}}$. Then \mathcal{F} is constructible if and only if $f^{-1}\mathcal{F}$ is constructible.*

Proof. One implication follows from Lemma 44.69.5. For the converse, assume $f^{-1}\mathcal{F}$ is constructible. Write $\mathcal{F} = \text{colim } \mathcal{F}_i$ as a filtered colimit of constructible sheaves (of sets, abelian groups, or modules) using Lemma 44.71.2. Since f^{-1} is a left adjoint it commutes with colimits (Categories, Lemma 4.24.4) and we see that $f^{-1}\mathcal{F} = \text{colim } f^{-1}\mathcal{F}_i$. By Lemma 44.69.9 we see that $f^{-1}\mathcal{F}_i \rightarrow f^{-1}\mathcal{F}$ is surjective for all i large enough. Since f is surjective we conclude (by looking at

stalks using Lemma 44.36.2 and Theorem 44.29.10) that $\mathcal{F}_i \rightarrow \mathcal{F}$ is surjective for all i large enough. Thus \mathcal{F} is the quotient of a constructible sheaf \mathcal{G} . Applying the argument once more to $\mathcal{G} \times_{\mathcal{F}} \mathcal{G}$ or the kernel of $\mathcal{G} \rightarrow \mathcal{F}$ we conclude using that f^{-1} is exact and that the category of constructible sheaves (of sets, abelian groups, or modules) is preserved under finite (co)limits or (co)kernels inside $Sh(Y_{\acute{e}tale})$, $Sh(X_{\acute{e}tale})$, $Ab(Y_{\acute{e}tale})$, $Ab(X_{\acute{e}tale})$, $Mod(Y_{\acute{e}tale}, \Lambda)$, and $Mod(X_{\acute{e}tale}, \Lambda)$, see Lemma 44.69.6. \square

Lemma 44.71.4. *Let $f : X \rightarrow Y$ be a finite étale morphism of schemes. Let Λ be a Noetherian ring. If \mathcal{F} is a constructible sheaf of sets, constructible sheaf of abelian groups, or constructible sheaf of Λ -modules on $X_{\acute{e}tale}$, the same is true for $f_*\mathcal{F}$ on $Y_{\acute{e}tale}$.*

Proof. By Lemma 44.69.4 it suffices to check this Zariski locally on Y and by Lemma 44.71.3 we may replace Y by an étale cover (the construction of f_* commutes with étale localization). A finite étale morphism is étale locally isomorphic to a disjoint union of isomorphisms, see Étale Morphisms, Lemma 40.18.3. Thus, in the case of sheaves of sets, the lemma says that if \mathcal{F}_i , $i = 1, \dots, n$ are constructible sheaves of sets, then $\coprod_{i=1, \dots, n} \mathcal{F}_i$ is too. This is clear. Similarly for sheaves of abelian groups and modules. \square

Lemma 44.71.5. *Let X be a quasi-compact and quasi-separated scheme. The category of constructible sheaves of sets is the full subcategory of $Sh(X_{\acute{e}tale})$ consisting of sheaves \mathcal{F} which are coequalizers*

$$\mathcal{F}_1 \rightrightarrows \mathcal{F}_0 \longrightarrow \mathcal{F}$$

such that \mathcal{F}_i , $i = 0, 1$ is a finite coproduct of sheaves of the form h_U with U a quasi-compact and quasi-separated object of $X_{\acute{e}tale}$.

Proof. In the proof of Lemma 44.71.2 we have seen that sheaves of this form are constructible. For the converse, suppose that for every constructible sheaf of sets \mathcal{F} we can find a surjection $\mathcal{F}_0 \rightarrow \mathcal{F}$ with \mathcal{F}_0 as in the lemma. Then we find our surjection $\mathcal{F}_1 \rightarrow \mathcal{F}_0 \times_{\mathcal{F}} \mathcal{F}_0$ because the latter is constructible by Lemma 44.69.6.

By Topology, Lemma 5.27.6 we may choose a finite stratification $X = \coprod_{i \in I} X_i$ such that \mathcal{F} is finite locally constant on each stratum. We will prove the result by induction on the cardinality of I . Let $i \in I$ be a minimal element in the partial ordering of I . Then $X_i \subset X$ is closed. By induction, there exist finitely many quasi-compact and quasi-separated objects U_α of $(X \setminus X_i)_{\acute{e}tale}$ and a surjective map $\coprod h_{U_\alpha} \rightarrow \mathcal{F}|_{X \setminus X_i}$. These determine a map

$$\coprod h_{U_\alpha} \rightarrow \mathcal{F}$$

which is surjective after restricting to $X \setminus X_i$. By Lemma 44.68.4 we see that $\mathcal{F}|_{X_i} = h_V$ for some scheme V finite étale over X_i . Let \bar{v} be a geometric point of V lying over $\bar{x} \in X_i$. We may think of \bar{v} as an element of the stalk $\mathcal{F}_{\bar{x}} = V_{\bar{x}}$. Thus we can find an étale neighbourhood (U, \bar{u}) of \bar{x} and a section $s \in \mathcal{F}(U)$ whose stalk at \bar{x} gives \bar{v} . Thinking of s as a map $s : h_U \rightarrow \mathcal{F}$, restricting to X_i we obtain a morphism $s|_{X_i} : U \times_X X_i \rightarrow V$ over X_i which maps \bar{u} to \bar{v} . Since V is quasi-compact (finite over the closed subscheme X_i of the quasi-compact scheme X) a

finite number $s^{(1)}, \dots, s^{(m)}$ of these sections of \mathcal{F} over $U^{(1)}, \dots, U^{(m)}$ will determine a jointly surjective map

$$\coprod s^{(j)}|_{X_i} : \coprod U^{(j)} \times_X X_i \longrightarrow V$$

Then we obtain the surjection

$$\coprod h_{U_\alpha} \amalg \coprod h_{U^{(j)}} \longrightarrow \mathcal{F}$$

as desired. □

Lemma 44.71.6. *Let X be a quasi-compact and quasi-separated scheme. Let Λ be a Noetherian ring. The category of constructible sheaves of Λ -modules is exactly the category of modules of the form*

$$\text{Coker} \left(\bigoplus_{j=1, \dots, m} j_{V_j!} \underline{\Lambda}_{V_j} \longrightarrow \bigoplus_{i=1, \dots, n} j_{U_i!} \underline{\Lambda}_{U_i} \right)$$

with V_j and U_i quasi-compact and quasi-separated objects of $X_{\text{étale}}$. In fact, we can even assume U_i and V_j affine.

Proof. In the proof of Lemma 44.71.2 we have seen modules of this form are constructible. Since the category of constructible modules is abelian (Lemma 44.69.6) it suffices to prove that given a constructible module \mathcal{F} there is a surjection

$$\bigoplus_{i=1, \dots, n} j_{U_i!} \underline{\Lambda}_{U_i} \longrightarrow \mathcal{F}$$

for some affine objects U_i in $X_{\text{étale}}$. By Modules on Sites, Lemma 18.29.6 there is a surjection

$$\Psi : \bigoplus_{i \in I} j_{U_i!} \underline{\Lambda}_{U_i} \longrightarrow \mathcal{F}$$

with U_i affine and the direct sum over a possibly infinite index set I . For every finite subset $I' \subset I$ set

$$T_{I'} = \text{Supp}(\text{Coker}(\bigoplus_{i \in I'} j_{U_i!} \underline{\Lambda}_{U_i} \longrightarrow \mathcal{F}))$$

By the very definition of constructible sheaves, the set $T_{I'}$ is a constructible subset of X . We want to show that $T_{I'} = \emptyset$ for some I' . Since every stalk $\mathcal{F}_{\bar{x}}$ is a finite type Λ -module and since Ψ is surjective, for every $x \in X$ there is an I' such that $x \notin T_{I'}$. In other words we have $\emptyset = \bigcap_{I' \subset I \text{ finite}} T_{I'}$. Since X is a spectral space by Properties, Lemma 27.2.4 the constructible topology on X is quasi-compact by Topology, Lemma 5.22.2. Thus $T_{I'} = \emptyset$ for some $I' \subset I$ finite as desired. □

Lemma 44.71.7. *Let X be a quasi-compact and quasi-separated scheme. The category of constructible abelian sheaves is exactly the category of abelian sheaves of the form*

$$\text{Coker} \left(\bigoplus_{j=1, \dots, m} j_{V_j!} \underline{\mathbf{Z}/m_j \mathbf{Z}}_{V_j} \longrightarrow \bigoplus_{i=1, \dots, n} j_{U_i!} \underline{\mathbf{Z}/n_i \mathbf{Z}}_{U_i} \right)$$

with V_j and U_i quasi-compact and quasi-separated objects of $X_{\text{étale}}$ and m_j, n_i positive integers. In fact, we can even assume U_i and V_j affine.

Proof. This follows from Lemma 44.71.6 applied with $\Lambda = \mathbf{Z}/n\mathbf{Z}$ and the fact that, since X is quasi-compact, every constructible abelian sheaf is annihilated by some positive integer n (details omitted). □

Lemma 44.71.8. *Let X be a quasi-compact and quasi-separated scheme. Let Λ be a Noetherian ring. Let \mathcal{F} be a constructible sheaf of sets, abelian groups, or Λ -modules on $X_{\text{étale}}$. Let $\mathcal{G} = \text{colim } \mathcal{G}_i$ be a filtered colimit of sheaves of sets, abelian groups, or Λ -modules. Then*

$$\text{Mor}(\mathcal{F}, \mathcal{G}) = \text{colim } \text{Mor}(\mathcal{F}, \mathcal{G}_i)$$

in the category of sheaves of sets, abelian groups, or Λ -modules on $X_{\text{étale}}$.

Proof. The case of sheaves of sets. By Lemma 44.71.5 it suffices to prove the lemma for h_U where U is a quasi-compact and quasi-separated object of $X_{\text{étale}}$. Recall that $\text{Mor}(h_U, \mathcal{G}) = \mathcal{G}(U)$. Hence the result follows from Sites, Lemma 7.11.2.

In the case of abelian sheaves or sheaves of modules, the result follows in the same way using Lemmas 44.71.7 and 44.71.6. For the case of abelian sheaves, we add that $\text{Mor}(j_{U!} \underline{\mathbf{Z}}/n\underline{\mathbf{Z}}, \mathcal{G})$ is equal to the n -torsion elements of $\mathcal{G}(U)$. \square

Lemma 44.71.9. *Let $f : X \rightarrow Y$ be a finite and finitely presented morphism of schemes. Let Λ be a Noetherian ring. If \mathcal{F} is a constructible sheaf of sets, abelian groups, or Λ -modules on $X_{\text{étale}}$, then $f_*\mathcal{F}$ is too.*

Proof. It suffices to prove this when X and Y are affine by Lemma 44.69.4. By Lemmas 44.55.3 and 44.71.3 we may base change to any affine scheme surjective over X . By Lemma 44.70.3 this reduces us to the case of a finite étale morphism (because a thickening leads to an equivalence of étale topoi and even small étale sites, see Theorem 44.46.1). The finite étale case is Lemma 44.71.4. \square

Lemma 44.71.10. *Let $X = \lim_{i \in I} X_i$ be a limit of a directed system of schemes with affine transition morphisms. We assume that X_i is quasi-compact and quasi-separated for all $i \in I$.*

- (1) *The category of constructible sheaves of sets on $X_{\text{étale}}$ is the colimit of the categories of constructible sheaves of sets on $(X_i)_{\text{étale}}$.*
- (2) *The category of constructible abelian sheaves on $X_{\text{étale}}$ is the colimit of the categories of constructible abelian sheaves on $(X_i)_{\text{étale}}$.*
- (3) *Let Λ be a Noetherian ring. The category of constructible sheaves of Λ -modules on $X_{\text{étale}}$ is the colimit of the categories of constructible sheaves of Λ -modules on $(X_i)_{\text{étale}}$.*

Proof. Proof of (1). Denote $f_i : X \rightarrow X_i$ the projection maps. There are 3 parts to the proof corresponding to “faithful”, “fully faithful”, and “essentially surjective”.

Faithful. Choose $0 \in I$ and let $\mathcal{F}_0, \mathcal{G}_0$ be constructible sheaves on X_0 . Suppose that $a, b : \mathcal{F}_0 \rightarrow \mathcal{G}_0$ are maps such that $f_0^{-1}a = f_0^{-1}b$. Let $E \subset X_0$ be the set of points $x \in X_0$ such that $a_{\bar{x}} = b_{\bar{x}}$. By Lemma 44.69.8 the subset $E \subset X_0$ is constructible. By assumption $X \rightarrow X_0$ maps into E . By Limits, Lemma 31.3.7 we find an $i \geq 0$ such that $X_i \rightarrow X_0$ maps into E . Hence $f_{i0}^{-1}a = f_{i0}^{-1}b$.

Fully faithful. Choose $0 \in I$ and let $\mathcal{F}_0, \mathcal{G}_0$ be constructible sheaves on X_0 . Suppose that $a : f_0^{-1}\mathcal{F}_0 \rightarrow f_0^{-1}\mathcal{G}_0$ is a map. We claim there is an i and a map $a_i : f_{i0}^{-1}\mathcal{F}_0 \rightarrow f_{i0}^{-1}\mathcal{G}_0$ which pulls back to a on X . By Lemma 44.71.5 we can replace \mathcal{F}_0 by a finite coproduct of sheaves represented by quasi-compact and quasi-separated objects of $(X_0)_{\text{étale}}$. Thus we have to show: If $U_0 \rightarrow X_0$ is such an object of $(X_0)_{\text{étale}}$, then

$$f_0^{-1}\mathcal{G}(U) = \text{colim}_{i \geq 0} f_{i0}^{-1}\mathcal{G}(U_i)$$

where $U = X \times_{X_0} U_0$ and $U_i = X_i \times_{X_0} U_0$. This is a special case of Theorem 44.52.1.

Essentially surjective. We have to show every constructible \mathcal{F} on X is isomorphic to $f_i^{-1}\mathcal{F}_i$ for some constructible \mathcal{F}_i on X_i . Applying Lemma 44.71.5 and using the results of the previous two paragraphs, we see that it suffices to prove this for h_U for some quasi-compact and quasi-separated object U of $X_{\acute{e}tale}$. In this case we have to show that U is the base change of a quasi-compact and quasi-separated scheme étale over X_i for some i . This follows from Limits, Lemmas 31.9.1 and 31.7.8.

Proof of (3). The argument is very similar to the argument for sheaves of sets, but using Lemma 44.71.6 instead of Lemma 44.71.5. Details omitted. Part (2) follows from part (3) because every constructible abelian sheaf over a quasi-compact scheme is a constructible sheaf of $\mathbf{Z}/n\mathbf{Z}$ -modules for some n . \square

Lemma 44.71.11. *Let X be an irreducible scheme with generic point η .*

- (1) *Let $S' \subset S$ be an inclusion of sets. If we have $\underline{S}' \subset \mathcal{G} \subset \underline{S}$ in $Sh(X_{\acute{e}tale})$ and $S' = \mathcal{G}_{\bar{\eta}}$, then $\mathcal{G} = \underline{S}'$.*
- (2) *Let $A' \subset A$ be an inclusion of abelian groups. If we have $\underline{A}' \subset \mathcal{G} \subset \underline{A}$ in $Ab(X_{\acute{e}tale})$ and $A' = \mathcal{G}_{\bar{\eta}}$, then $\mathcal{G} = \underline{A}'$.*
- (3) *Let $M' \subset M$ be an inclusion of modules over a ring Λ . If we have $\underline{M}' \subset \mathcal{G} \subset \underline{M}$ in $Mod(X_{\acute{e}tale}, \Lambda)$ and $M' = \mathcal{G}_{\bar{\eta}}$, then $\mathcal{G} = \underline{M}'$.*

Proof. This is true because for every étale morphism $U \rightarrow X$ with $U \neq \emptyset$ the point η is in the image. \square

Lemma 44.71.12. *Let X be an integral normal scheme with function field K . Let E be a set.*

- (1) *Let $g : \text{Spec}(K) \rightarrow X$ be the inclusion of the generic point. Then $g_*\underline{E} = \underline{E}$.*
- (2) *Let $j : U \rightarrow X$ be the inclusion of a nonempty open. Then $j_*\underline{E} = \underline{E}$.*

Proof. Proof of (1). Let $x \in X$ be a point. Let $\mathcal{O}_{X,\bar{x}}$ be a strict henselization of $\mathcal{O}_{X,x}$. By More on Algebra, Lemma 15.34.6 we see that $\mathcal{O}_{X,\bar{x}}$ is a normal domain. Hence $\text{Spec}(K) \times_X \text{Spec}(\mathcal{O}_{X,\bar{x}})$ is irreducible. It follows that the stalk $(g_*\underline{E})_x$ is equal to E , see Theorem 44.53.1.

Proof of (2). Since g factors through j there is a map $j_*\underline{E} \rightarrow g_*\underline{E}$. This map is injective because for every scheme V étale over X the set $\text{Spec}(K) \times_X V$ is dense in $U \times_X V$. On the other hand, we have a map $\underline{E} \rightarrow j_*\underline{E}$ and we conclude. \square

44.72. Constructible sheaves on Noetherian schemes

If X is a Noetherian scheme then any locally closed subset is a constructible locally closed subset (Topology, Lemma 5.15.1). Hence an abelian sheaf \mathcal{F} on $X_{\acute{e}tale}$ is constructible if and only if there exists a finite partition $X = \coprod X_i$ such that $\mathcal{F}|_{X_i}$ is finite locally constant. (By convention a partition of a topological space has locally closed parts, see Topology, Section 5.27.) In other words, we can omit the adjective “constructible” in Definition 44.69.1. Actually, the category of constructible sheaves on Noetherian schemes has some additional properties which we will catalogue in this section.

Proposition 44.72.1. *Let X be a Noetherian scheme. Let Λ be a Noetherian ring.*

- (1) *Any sub or quotient sheaf of a constructible sheaf of sets is constructible.*

- (2) *The category of constructible abelian sheaves on $X_{\text{étale}}$ is a (strong) Serre subcategory of $\text{Ab}(X_{\text{étale}})$. In particular, every sub and quotient sheaf of a constructible abelian sheaf on $X_{\text{étale}}$ is constructible.*
- (3) *The category of constructible sheaves of Λ -modules on $X_{\text{étale}}$ is a (strong) Serre subcategory of $\text{Mod}(X_{\text{étale}}, \Lambda)$. In particular, every submodule and quotient module of a constructible sheaf of Λ -modules on $X_{\text{étale}}$ is constructible.*

Proof. Proof of (1). Let $\mathcal{G} \subset \mathcal{F}$ with \mathcal{F} a constructible sheaf of sets on $X_{\text{étale}}$. Let $\eta \in X$ be a generic point of an irreducible component of X . By Noetherian induction it suffices to find an open neighbourhood U of η such that $\mathcal{G}|_U$ is locally constant. To do this we may replace X by an étale neighbourhood of η . Hence we may assume \mathcal{F} is constant and X is irreducible.

Say $\mathcal{F} = \underline{S}$ for some finite set S . Then $S' = \mathcal{G}_{\bar{\eta}} \subset S$ say $S' = \{s_1, \dots, s_t\}$. Pick an étale neighbourhood (U, \bar{u}) of $\bar{\eta}$ and sections $\sigma_1, \dots, \sigma_t \in \mathcal{G}(U)$ which map to s_i in $\mathcal{G}_{\bar{\eta}} \subset S$. Since σ_i maps to an element $s_i \in S' \subset S = \Gamma(X, \mathcal{F})$ we see that the two pullbacks of σ_i to $U \times_X U$ are the same as sections of \mathcal{G} . By the sheaf condition for \mathcal{G} we find that σ_i comes from a section of \mathcal{G} over the open $\text{Im}(U \rightarrow X)$ of X . Shrinking X we may assume $\underline{S}' \subset \mathcal{G} \subset \underline{S}$. Then we see that $\underline{S}' = \mathcal{G}$ by Lemma 44.71.11.

Let $\mathcal{F} \rightarrow \mathcal{Q}$ be a surjection with \mathcal{F} a constructible sheaf of sets on $X_{\text{étale}}$. Then set $\mathcal{G} = \mathcal{F} \times_{\mathcal{Q}} \mathcal{F}$. By the first part of the proof we see that \mathcal{G} is constructible as a subsheaf of $\mathcal{F} \times \mathcal{F}$. This in turn implies that \mathcal{Q} is constructible, see Lemma 44.69.6.

Proof of (3). we already know that constructible sheaves of modules form a weak Serre subcategory, see Lemma 44.69.6. Thus it suffices to show the statement on submodules.

Let $\mathcal{G} \subset \mathcal{F}$ be a submodule of a constructible sheaf of Λ -modules on $X_{\text{étale}}$. Let $\eta \in X$ be a generic point of an irreducible component of X . By Noetherian induction it suffices to find an open neighbourhood U of η such that $\mathcal{G}|_U$ is locally constant. To do this we may replace X by an étale neighbourhood of η . Hence we may assume \mathcal{F} is constant and X is irreducible.

Say $\mathcal{F} = \underline{M}$ for some finite Λ -module M . Then $M' = \mathcal{G}_{\bar{\eta}} \subset M$. Pick finitely many elements s_1, \dots, s_t generating M' as a Λ -module. (This is possible as Λ is Noetherian and M is finite.) Pick an étale neighbourhood (U, \bar{u}) of $\bar{\eta}$ and sections $\sigma_1, \dots, \sigma_t \in \mathcal{G}(U)$ which map to s_i in $\mathcal{G}_{\bar{\eta}} \subset M$. Since σ_i maps to an element $s_i \in M' \subset M = \Gamma(X, \mathcal{F})$ we see that the two pullbacks of σ_i to $U \times_X U$ are the same as sections of \mathcal{G} . By the sheaf condition for \mathcal{G} we find that σ_i comes from a section of \mathcal{G} over the open $\text{Im}(U \rightarrow X)$ of X . Shrinking X we may assume $\underline{M}' \subset \mathcal{G} \subset \underline{M}$. Then we see that $\underline{M}' = \mathcal{G}$ by Lemma 44.71.11.

Proof of (2). This follows in the usual manner from (3). Details omitted. \square

The following lemma tells us that every object of the abelian category of constructible sheaves on X is “Noetherian”, i.e., satisfies a.c.c. for subobjects.

Lemma 44.72.2. *Let X be a Noetherian scheme. Let Λ be a Noetherian ring. Consider inclusions*

$$\mathcal{F}_1 \subset \mathcal{F}_2 \subset \mathcal{F}_3 \subset \dots \subset \mathcal{F}$$

in the category of sheaves of sets, abelian groups, or Λ -modules. If \mathcal{F} is constructible, then for some n we have $\mathcal{F}_n = \mathcal{F}_{n+1} = \mathcal{F}_{n+2} = \dots$

Proof. By Proposition 44.72.1 we see that \mathcal{F}_i and $\text{colim } \mathcal{F}_i$ are constructible. Then the lemma follows from Lemma 44.69.9. \square

Lemma 44.72.3. *Let X be a Noetherian scheme.*

- (1) *Let \mathcal{F} be a constructible sheaf of sets on $X_{\text{étale}}$. There exist an injective map of sheaves*

$$\mathcal{F} \longrightarrow \coprod_{i=1, \dots, n} f_{i,*} \underline{E}_i$$

where $f_i : Y_i \rightarrow X$ is a finite morphism and E_i is a finite set.

- (2) *Let \mathcal{F} be a constructible abelian sheaf on $X_{\text{étale}}$. There exist an injective map of abelian sheaves*

$$\mathcal{F} \longrightarrow \bigoplus_{i=1, \dots, n} f_{i,*} \underline{M}_i$$

where $f_i : Y_i \rightarrow X$ is a finite morphism and M_i is a finite abelian group.

- (3) *Let Λ be a Noetherian ring. Let \mathcal{F} be a constructible sheaf of Λ -modules on $X_{\text{étale}}$. There exist an injective map of sheaves of modules*

$$\mathcal{F} \longrightarrow \bigoplus_{i=1, \dots, n} f_{i,*} \underline{M}_i$$

where $f_i : Y_i \rightarrow X$ is a finite morphism and M_i is a finite Λ -module.

Moreover, we may assume each Y_i is irreducible, reduced, maps onto an irreducible and reduced closed subscheme $Z_i \subset X$ such that $Y_i \rightarrow Z_i$ is finite étale over a nonempty open of Z_i .

Proof. Proof of (1). Because we have the ascending chain condition for subsheaves of \mathcal{F} (Lemma 44.72.2), it suffices to show that for every point $x \in X$ we can find a map $\varphi : \mathcal{F} \rightarrow f_* \underline{E}$ where $f : Y \rightarrow X$ is finite and E is a finite set such that $\varphi_{\bar{x}} : \mathcal{F}_{\bar{x}} \rightarrow (f_* \underline{E})_{\bar{x}}$ is injective. (This argument can be avoided by picking a partition of X as in Lemma 44.69.2 and constructing a $Y_i \rightarrow X$ for each irreducible component of each part.) Let $Z \subset X$ be the induced reduced scheme structure (Schemes, Definition 25.12.5) on $\overline{\{x\}}$. Since \mathcal{F} is constructible, there is a finite separable extension $\kappa(x) \subset \text{Spec}(K)$ such that $\mathcal{F}|_{\text{Spec}(K)}$ is the constant sheaf with value E for some finite set E . Let $Y \rightarrow Z$ be the normalization of Z in $\text{Spec}(K)$. By Morphisms, Lemma 28.48.10 we see that Y is a normal integral scheme. As $\kappa(x) \subset K$ is finite, it is clear that K is the function field of Y . Denote $g : \text{Spec}(K) \rightarrow Y$ the inclusion. The map $\mathcal{F}|_{\text{Spec}(K)} \rightarrow \underline{E}$ is adjoint to a map $\mathcal{F}|_Y \rightarrow g_* \underline{E} = \underline{E}$ (Lemma 44.71.12). This in turn is adjoint to a map $\varphi : \mathcal{F} \rightarrow f_* \underline{E}$. Observe that the stalk of φ at a geometric point \bar{x} is injective: we may take a lift $\bar{y} \in Y$ of \bar{x} and the commutative diagram

$$\begin{array}{ccc} \mathcal{F}_{\bar{x}} & \xlongequal{\quad} & (\mathcal{F}|_Y)_{\bar{y}} \\ \downarrow & & \parallel \\ (f_* \underline{E})_{\bar{x}} & \longrightarrow & \underline{E}_{\bar{y}} \end{array}$$

proves the injectivity. We are not yet done, however, as the morphism $f : Y \rightarrow Z$ is integral but in general not finite⁵.

⁵If X is a Nagata scheme, for example of finite type over a field, then $Y \rightarrow Z$ is finite.

To fix the problem stated in the last sentence of the previous paragraph, we write $Y = \lim_{i \in I} Y_i$ with Y_i irreducible, integral, and finite over Z . Namely, apply Properties, Lemma 27.20.13 to $f_*\mathcal{O}_Y$ viewed as a sheaf of \mathcal{O}_Z -algebras and apply the functor $\underline{\text{Spec}}_Z$. Then $f_*\underline{E} = \text{colim } f_{i,*}\underline{E}$ by Lemma 44.52.5. By Lemma 44.71.8 the map $\mathcal{F} \rightarrow f_*\underline{E}$ factors through $f_{i,*}\underline{E}$ for some i . Since $Y_i \rightarrow Z$ is a finite morphism of integral schemes and since the function field extension induced by this morphism is finite separable, we see that the morphism is finite étale over a nonempty open of Z (use Algebra, Lemma 10.135.9; details omitted). This finishes the proof of (1).

The proofs of (2) and (3) are identical to the proof of (1). □

In the following lemma we use a standard trick to reduce a very general statement to the Noetherian case.

Lemma 44.72.4. *Let X be a quasi-compact and quasi-separated scheme.*

- (1) *Let \mathcal{F} be a constructible sheaf of sets on $X_{\text{étale}}$. There exist an injective map of sheaves*

$$\mathcal{F} \longrightarrow \prod_{i=1, \dots, n} f_{i,*}\underline{E}_i$$

where $f_i : Y_i \rightarrow X$ is a finite and finitely presented morphism and E_i is a finite set.

- (2) *Let \mathcal{F} be a constructible abelian sheaf on $X_{\text{étale}}$. There exist an injective map of abelian sheaves*

$$\mathcal{F} \longrightarrow \bigoplus_{i=1, \dots, n} f_{i,*}\underline{M}_i$$

where $f_i : Y_i \rightarrow X$ is a finite and finitely presented morphism and M_i is a finite abelian group.

- (3) *Let Λ be a Noetherian ring. Let \mathcal{F} be a constructible sheaf of Λ -modules on $X_{\text{étale}}$. There exist an injective map of sheaves of modules*

$$\mathcal{F} \longrightarrow \bigoplus_{i=1, \dots, n} f_{i,*}\underline{M}_i$$

where $f_i : Y_i \rightarrow X$ is a finite and finitely presented morphism and M_i is a finite Λ -module.

Proof. We will reduce this lemma to the Noetherian case by absolute Noetherian approximation. Namely, by Limits, Proposition 31.4.4 we can write $X = \lim_{t \in T} X_t$ with each X_t of finite type over $\text{Spec}(\mathbf{Z})$ and with affine transition morphisms. By Lemma 44.71.10 the category of constructible sheaves (of sets, abelian groups, or Λ -modules) on $X_{\text{étale}}$ is the colimit of the corresponding categories for X_t . Thus our constructible sheaf \mathcal{F} is the pullback of a similar constructible sheaf \mathcal{F}_t over X_t for some t . Then we apply the Noetherian case (Lemma 44.72.3) to find an injection

$$\mathcal{F}_t \longrightarrow \prod_{i=1, \dots, n} f_{i,*}\underline{E}_i \quad \text{or} \quad \mathcal{F}_t \longrightarrow \bigoplus_{i=1, \dots, n} f_{i,*}\underline{M}_i$$

over X_t for some finite morphisms $f_i : Y_i \rightarrow X_t$. Since X_t is Noetherian the morphisms f_i are of finite presentation. Since pullback is exact and since formation of $f_{i,*}$ commutes with base change (Lemma 44.55.3), we conclude. □

44.73. Cohomology with support in a closed subscheme

Let X be a scheme and let $Z \subset X$ be a closed subscheme. Let \mathcal{F} be an abelian sheaf on $X_{\acute{e}tale}$. We let

$$\Gamma_Z(X, \mathcal{F}) = \{s \in \mathcal{F}(X) \mid \text{Supp}(s) \subset Z\}$$

be the sections with support in Z (Definition 44.31.3). This is a left exact functor which is not exact in general. Hence we obtain a derived functor

$$R\Gamma_Z(X, -) : D(X_{\acute{e}tale}) \longrightarrow D(\text{Ab})$$

and cohomology groups with support in Z defined by $H_Z^q(X, \mathcal{F}) = R^q\Gamma_Z(X, \mathcal{F})$.

Let \mathcal{I} be an injective abelian sheaf on $X_{\acute{e}tale}$. Let $U = X \setminus Z$. Then the restriction map $\mathcal{I}(X) \rightarrow \mathcal{I}(U)$ is surjective (Cohomology on Sites, Lemma 21.12.6) with kernel $\Gamma_Z(X, \mathcal{I})$. It immediately follows that for $K \in D(X_{\acute{e}tale})$ there is a distinguished triangle

$$R\Gamma_Z(X, K) \rightarrow R\Gamma(X, K) \rightarrow R\Gamma(U, K) \rightarrow R\Gamma_Z(X, K)[1]$$

in $D(\text{Ab})$. As a consequence we obtain a long exact cohomology sequence

$$\dots \rightarrow H_Z^i(X, K) \rightarrow H^i(X, K) \rightarrow H^i(U, K) \rightarrow H_Z^{i+1}(X, K) \rightarrow \dots$$

for any K in $D(X_{\acute{e}tale})$.

For an abelian sheaf \mathcal{F} on $X_{\acute{e}tale}$ we can consider the *subsheaf of sections with support in Z* , denoted $\mathcal{H}_Z(\mathcal{F})$, defined by the rule

$$\mathcal{H}_Z(\mathcal{F})(U) = \{s \in \mathcal{F}(U) \mid \text{Supp}(s) \subset U \times_X Z\}$$

Here we use the support of a section from Definition 44.31.3. Using the equivalence of Proposition 44.47.4 we may view $\mathcal{H}_Z(\mathcal{F})$ as an abelian sheaf on $Z_{\acute{e}tale}$. Thus we obtain a functor

$$\text{Ab}(X_{\acute{e}tale}) \longrightarrow \text{Ab}(Z_{\acute{e}tale}), \quad \mathcal{F} \longmapsto \mathcal{H}_Z(\mathcal{F})$$

which is left exact, but in general not exact.

Lemma 44.73.1. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. Let \mathcal{I} be an injective abelian sheaf on $X_{\acute{e}tale}$. Then $\mathcal{H}_Z(\mathcal{I})$ is an injective abelian sheaf on $Z_{\acute{e}tale}$.*

Proof. Observe that for any abelian sheaf \mathcal{G} on $Z_{\acute{e}tale}$ we have

$$\text{Hom}_Z(\mathcal{G}, \mathcal{H}_Z(\mathcal{F})) = \text{Hom}_X(i_*\mathcal{G}, \mathcal{F})$$

because after all any section of $i_*\mathcal{G}$ has support in Z . Since i_* is exact (Section 44.47) and as \mathcal{I} is injective on $X_{\acute{e}tale}$ we conclude that $\mathcal{H}_Z(\mathcal{I})$ is injective on $Z_{\acute{e}tale}$. \square

Denote

$$R\mathcal{H}_Z : D(X_{\acute{e}tale}) \longrightarrow D(Z_{\acute{e}tale})$$

the derived functor. We set $\mathcal{H}_Z^q(\mathcal{F}) = R^q\mathcal{H}_Z(\mathcal{F})$ so that $\mathcal{H}_Z^0(\mathcal{F}) = \mathcal{H}_Z(\mathcal{F})$. By the lemma above we have a Grothendieck spectral sequence

$$E_2^{p,q} = H^p(Z, \mathcal{H}_Z^q(\mathcal{F})) \Rightarrow H_Z^{p+q}(X, \mathcal{F})$$

Lemma 44.73.2. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. Let \mathcal{G} be an injective abelian sheaf on $Z_{\acute{e}tale}$. Then $\mathcal{H}_Z^p(i_*\mathcal{G}) = 0$ for $p > 0$.*

Proof. This is true because the functor i_* is exact and transforms injective abelian sheaves into injective abelian sheaves (Cohomology on Sites, Lemma 21.14.2). \square

Lemma 44.73.3. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. Let $j : U \rightarrow X$ be the inclusion of the complement of Z . Let \mathcal{F} be an abelian sheaf on $X_{\acute{e}tale}$. There is a distinguished triangle*

$$i_*R\mathcal{H}_Z(\mathcal{F}) \rightarrow \mathcal{F} \rightarrow Rj_*(\mathcal{F}|_U) \rightarrow i_*R\mathcal{H}_Z(\mathcal{F})[1]$$

in $D(X_{\acute{e}tale})$. This produces an exact sequence

$$0 \rightarrow i_*\mathcal{H}_Z(\mathcal{F}) \rightarrow \mathcal{F} \rightarrow j_*(\mathcal{F}|_U) \rightarrow i_*\mathcal{H}_Z^1(\mathcal{F}) \rightarrow 0$$

and isomorphisms $R^pj_*(\mathcal{F}|_U) \cong i_*\mathcal{H}_Z^{p+1}(\mathcal{F})$ for $p \geq 1$.

Proof. To get the distinguished triangle, choose an injective resolution $\mathcal{F} \rightarrow \mathcal{I}^\bullet$. Then we obtain a short exact sequence of complexes

$$0 \rightarrow i_*\mathcal{H}_Z(\mathcal{I}^\bullet) \rightarrow \mathcal{I}^\bullet \rightarrow j_*(\mathcal{I}^\bullet|_U) \rightarrow 0$$

by the discussion above. Thus the distinguished triangle by Derived Categories, Section 13.12. □

Let X be a scheme and let $Z \subset X$ be a closed subscheme. We denote $D_Z(X_{\acute{e}tale})$ the strictly full saturated triangulated subcategory of $D(X_{\acute{e}tale})$ consisting of complexes whose cohomology sheaves are supported on Z . Note that $D_Z(X_{\acute{e}tale})$ only depends on the underlying closed subset of X .

Lemma 44.73.4. *Let $i : Z \rightarrow X$ be a closed immersion of schemes. The map $Ri_{small,*} = i_{small,*} : D(Z_{\acute{e}tale}) \rightarrow D(X_{\acute{e}tale})$ induces an equivalence $D(Z_{\acute{e}tale}) \rightarrow D_Z(X_{\acute{e}tale})$ with quasi-inverse*

$$i_{small}^{-1}|_{D_Z(X_{\acute{e}tale})} = R\mathcal{H}_Z|_{D_Z(X_{\acute{e}tale})}$$

Proof. Recall that i_{small}^{-1} and $i_{small,*}$ is an adjoint pair of exact functors such that $i_{small}^{-1}i_{small,*}$ is isomorphic to the identify functor on abelian sheaves. See Proposition 44.47.4 and Lemma 44.36.2. Thus $i_{small,*} : D(Z_{\acute{e}tale}) \rightarrow D_Z(X_{\acute{e}tale})$ is fully faithful and i_{small}^{-1} determines a left inverse. On the other hand, suppose that K is an object of $D_Z(X_{\acute{e}tale})$ and consider the adjunction map $K \rightarrow i_{small,*}i_{small}^{-1}K$. Using exactness of $i_{small,*}$ and i_{small}^{-1} this induces the adjunction maps $H^n(K) \rightarrow i_{small,*}i_{small}^{-1}H^n(K)$ on cohomology sheaves. Since these cohomology sheaves are supported on Z we see these adjunction maps are isomorphisms and we conclude that $D(Z_{\acute{e}tale}) \rightarrow D_Z(X_{\acute{e}tale})$ is an equivalence.

To finish the proof we have to show that $R\mathcal{H}_Z(K) = i_{small}^{-1}K$ if K is an object of $D_Z(X_{\acute{e}tale})$. To do this we can use that $K = i_{small,*}i_{small}^{-1}K$ as we've just proved this is the case. Then we can choose a K-injective representative \mathcal{I}^\bullet for $i_{small}^{-1}K$. Since $i_{small,*}$ is the right adjoint to the exact functor i_{small}^{-1} , the complex $i_{small,*}\mathcal{I}^\bullet$ is K-injective (Derived Categories, Lemma 13.29.10). We see that $R\mathcal{H}_Z(K)$ is computed by $\mathcal{H}_Z(i_{small,*}\mathcal{I}^\bullet) = \mathcal{I}^\bullet$ as desired. □

Lemma 44.73.5. *Let X be a scheme. Let $Z \subset X$ be a closed subscheme. Let \mathcal{F} be a quasi-coherent \mathcal{O}_X -module and denote \mathcal{F}^a the associated quasi-coherent sheaf on the small étale site of X (Proposition 44.17.1). Then*

- (1) $H_Z^q(X, \mathcal{F})$ agrees with $H_Z^q(X_{\acute{e}tale}, \mathcal{F}^a)$,
- (2) if the complement of Z is retrocompact in X , then $i_*\mathcal{H}_Z^q(\mathcal{F}^a)$ is a quasi-coherent sheaf of \mathcal{O}_X -modules equal to $(i_*\mathcal{H}^q(\mathcal{F}))^a$.

Proof. Let $j : U \rightarrow X$ be the inclusion of the complement of Z . The statement (1) on cohomology groups follows from the long exact sequences for cohomology with supports and the agreements $H^q(X_{\text{étale}}, \mathcal{F}^a) = H^q(X, \mathcal{F})$ and $H^q(U_{\text{étale}}, \mathcal{F}^a) = H^q(U, \mathcal{F})$, see Theorem 44.22.4. If $j : U \rightarrow X$ is a quasi-compact morphism, i.e., if $U \subset X$ is retrocompact, then $R^q j_*$ transforms quasi-coherent sheaves into quasi-coherent sheaves (Cohomology of Schemes, Lemma 29.4.4) and commutes with taking associated sheaf on étale sites (Descent, Lemma 34.7.15). We conclude by applying Lemma 44.73.3. \square

44.74. Affine analog of proper base change

In this section we discuss a result by Ofer Gabber, see [Gab94]. This was also proved by Roland Huber, see [Hub93b].

Lemma 44.74.1. *Let X be an integral normal scheme with separably closed function field.*

- (1) *A separated étale morphism $U \rightarrow X$ is a disjoint union of open immersions.*
- (2) *All local rings of X are strictly henselian.*

Proof. Let R be a normal domain whose fraction field is separably algebraically closed. Let $R \rightarrow A$ be an étale ring map. Then $A \otimes_R K$ is as a K -algebra a finite product $\prod_{i=1, \dots, n} K$ of copies of K . Let e_i , $i = 1, \dots, n$ be the corresponding idempotents of $A \otimes_R K$. Since A is normal (Algebra, Lemma 10.151.7) the idempotents e_i are in A (Algebra, Lemma 10.36.11). Hence $A = \prod A e_i$ and we may assume $A \otimes_R K = K$. Since $A \subset A \otimes_R K = K$ (by flatness of $R \rightarrow A$ and since $R \subset K$) we conclude that A is a domain. By the same argument we conclude that $A \otimes_R A \subset (A \otimes_R A) \otimes_R K = K$. It follows that the map $A \otimes_R A \rightarrow A$ is injective as well as surjective. Thus $R \rightarrow A$ defines an open immersion by Morphisms, Lemma 28.12.2 and Étale Morphisms, Theorem 40.14.1.

Let $f : U \rightarrow X$ be a separated étale morphism. Let $\eta \in X$ be the generic point and let $f^{-1}(\{\eta\}) = \{\xi_i\}_{i \in I}$. The result of the previous paragraph shows the following: For any affine open $U' \subset U$ whose image in X is contained in an affine we have $U' = \coprod_{i \in I} U'_i$ where U'_i is the set of point of U' which are specializations of ξ_i . Moreover, the morphism $U'_i \rightarrow X$ is an open immersion. It follows that $U_i = \overline{\{\xi_i\}}$ is an open and closed subscheme of U and that $U_i \rightarrow X$ is locally on the source an isomorphism. By Morphisms, Lemma 28.10.6 the fact that $U_i \rightarrow X$ is separated, implies that $U_i \rightarrow X$ is injective and we conclude that $U_i \rightarrow X$ is an open immersion, i.e., (1) holds.

Part (2) follows from part (1) and the description of the strict henselization of $\mathcal{O}_{X, \bar{x}}$ as the local ring at \bar{x} on the étale site of X (Lemma 44.33.1). \square

Lemma 44.74.2. *Let X be an affine integral normal scheme with separably closed function field. Let $Z \subset X$ be a closed subscheme. Let $V \rightarrow Z$ be an étale morphism with V affine. Then V is a finite disjoint union of open subschemes of Z . If $V \rightarrow Z$ is surjective and finite étale, then $V \rightarrow Z$ has a section.*

Proof. By Algebra, Lemma 10.138.11 we can lift V to an affine scheme U étale over X . Apply Lemma 44.74.1 to $U \rightarrow X$ to get the first statement.

The final statement is a consequence of the first. Let $V = \coprod_{i=1, \dots, n} V_i$ be a finite decomposition into open and closed subschemes with $V_i \rightarrow Z$ an open immersion. As $V \rightarrow Z$ is finite we see that $V_i \rightarrow Z$ is also closed. Let $U_i \subset Z$ be the image. Then we have a decomposition into open and closed subschemes

$$Z = \coprod_{(A,B)} \bigcap_{i \in A} U_i \cap \bigcap_{i \in B} U_i^c$$

where the disjoint union is over $\{1, \dots, n\} = A \amalg B$ where A has at least one element. Each of the strata is contained in a single U_i and we find our section. \square

Lemma 44.74.3. *Let X be a normal integral affine scheme with with separably closed function field. Let $Z \subset X$ be a closed subscheme. For any finite abelian group M we have $H_{\text{étale}}^1(Z, \underline{M}) = 0$.*

Proof. By Cohomology on Sites, Lemma 21.5.3 an element of $H_{\text{étale}}^1(Z, \underline{M})$ corresponds to a \underline{M} -torsor \mathcal{F} on $Z_{\text{étale}}$. Such a torsor is clearly a finite locally constant sheaf. Hence \mathcal{F} is representable by a scheme V finite étale over Z , Lemma 44.68.4. Of course $V \rightarrow Z$ is surjective as a torsor is locally trivial. Since $V \rightarrow Z$ has a section by Lemma 44.74.2 we are done. \square

Lemma 44.74.4. *Let X be a normal integral affine scheme with separably closed function field. Let $Z \subset X$ be a closed subscheme. For any finite abelian group M we have $H_{\text{étale}}^q(Z, \underline{M}) = 0$ for $q \geq 1$.*

Proof. We have seen that the result is true for H^1 in Lemma 44.74.3. We will prove the result for $q \geq 2$ by induction on q . Let $\xi \in H_{\text{étale}}^q(Z, \underline{M})$.

Let $X = \text{Spec}(R)$. Let $I \subset R$ be the set of elements $f \in R$ such that $\xi|_{Z \cap D(f)} = 0$. All local rings of Z are strictly henselian by Lemma 44.74.1 and Algebra, Lemma 10.145.30. Hence étale cohomology on Z or open subschemes of Z is equal to Zariski cohomology, see Lemma 44.55.6. In particular ξ is Zariski locally trivial. It follows that for every prime \mathfrak{p} of R there exists an $f \in I$ with $f \notin \mathfrak{p}$. Thus if we can show that I is an ideal, then $1 \in I$ and we're done. It is clear that $f \in I, r \in R$ implies $rf \in I$. Thus we now assume that $f, g \in I$ and we show that $f + g \in I$. Note that

$$D(f + g) \cap Z = D(f(f + g)) \cap Z \cup D(g(f + g)) \cap Z$$

By Mayer-Vietoris (Cohomology, Lemma 20.9.2 which applies as étale cohomology on open subschemes of Z equals Zariski cohomology) we have an exact sequence

$$\begin{array}{c} H_{\text{étale}}^{q-1}(D(fg(f + g)) \cap Z, \underline{M}) \\ \downarrow \\ H_{\text{étale}}^q(D(f + g) \cap Z, \underline{M}) \\ \downarrow \\ H_{\text{étale}}^q(D(f(f + g)) \cap Z, \underline{M}) \oplus H_{\text{étale}}^q(D(g(f + g)) \cap Z, \underline{M}) \end{array}$$

and the result follows as the first group is zero by induction. \square

Lemma 44.74.5. *Let X be an affine scheme.*

- (1) *There exists an integral surjective morphism $X' \rightarrow X$ such that for every closed subscheme $Z' \subset X'$, every finite abelian group M , and every $q \geq 1$ we have $H_{\text{étale}}^q(Z', \underline{M}) = 0$.*

- (2) For any closed subscheme $Z \subset X$, finite abelian group M , $q \geq 1$, and $\xi \in H_{\text{étale}}^q(Z, \underline{M})$ there exists a finite surjective morphism $X' \rightarrow X$ of finite presentation such that ξ pulls back to zero in $H_{\text{étale}}^q(X' \times_X Z, \underline{M})$.

Proof. Write $X = \text{Spec}(A)$. Write $A = \mathbf{Z}[x_i]/J$ for some ideal J . Let R be the integral closure of $\mathbf{Z}[x_i]$ in an algebraic closure of the fraction field of $\mathbf{Z}[x_i]$. Let $A' = R/JR$ and set $X' = \text{Spec}(A')$. This gives an example as in (1) by Lemma 44.74.4.

Proof of (2). Let $X' \rightarrow X$ be the integral surjective morphism we found above. Certainly, ξ maps to zero in $H_{\text{étale}}^q(X' \times_X Z, \underline{M})$. We may write X' as a limit $X' = \lim X'_i$ of schemes finite and of finite presentation over X ; this is easy to do in our current affine case, but it is a special case of the more general Limits, Lemma 31.6.2. By Lemma 44.52.3 we see that ξ maps to zero in $H_{\text{étale}}^q(X'_i \times_X Z, \underline{M})$ for some i large enough. \square

Lemma 44.74.6. Let X be an affine scheme. Let \mathcal{F} be a torsion abelian sheaf on $X_{\text{étale}}$. Let $Z \subset X$ be a closed subscheme. Let $\xi \in H_{\text{étale}}^q(Z, \mathcal{F}|_Z)$ for some $q > 0$. Then there exists an injective map $\mathcal{F} \rightarrow \mathcal{F}'$ of torsion abelian sheaves on $X_{\text{étale}}$ such that the image of ξ in $H_{\text{étale}}^q(Z, \mathcal{F}'|_Z)$ is zero.

Proof. By Lemmas 44.71.2 and 44.52.2 we can find a map $\mathcal{G} \rightarrow \mathcal{F}$ with \mathcal{G} a constructible abelian sheaf and ξ coming from an element ζ of $H_{\text{étale}}^q(Z, \mathcal{G}|_Z)$. Suppose we can find an injective map $\mathcal{G} \rightarrow \mathcal{G}'$ of torsion abelian sheaves on $X_{\text{étale}}$ such that the image of ζ in $H_{\text{étale}}^q(Z, \mathcal{G}'|_Z)$ is zero. Then we can take \mathcal{F}' to be the pushout

$$\mathcal{F}' = \mathcal{G}' \amalg_{\mathcal{G}} \mathcal{F}$$

and we conclude the result of the lemma holds. (Observe that restriction to Z is exact, so commutes with finite limits and colimits and moreover it commutes with arbitrary colimits as a left adjoint to pushforward.) Thus we may assume \mathcal{F} is constructible.

Assume \mathcal{F} is constructible. By Lemma 44.72.4 it suffices to prove the result when \mathcal{F} is of the form $f_*\underline{M}$ where M is a finite abelian group and $f : Y \rightarrow X$ is a finite morphism of finite presentation (such sheaves are still constructible by Lemma 44.71.9 but we won't need this). Since formation of f_* commutes with any base change (Lemma 44.55.3) we see that the restriction of $f_*\underline{M}$ to Z is equal to the pushforward of \underline{M} via $Y \times_X Z \rightarrow Z$. By the Leray spectral sequence (Proposition 44.54.2) and vanishing of higher direct images (Proposition 44.55.2), we find

$$H_{\text{étale}}^q(Z, f_*\underline{M}|_Z) = H_{\text{étale}}^q(Y \times_X Z, \underline{M}).$$

By Lemma 44.74.5 we can find a finite surjective morphism $Y' \rightarrow Y$ of finite presentation such that ξ maps to zero in $H^q(Y' \times_X Z, \underline{M})$. Denoting $f' : Y' \rightarrow X$ the composition $Y' \rightarrow Y \rightarrow X$ we claim the map

$$f_*\underline{M} \longrightarrow f'_*\underline{M}$$

is injective which finishes the proof by what was said above. To see the desired injectivity we can look at stalks. Namely, if $\bar{x} : \text{Spec}(k) \rightarrow X$ is a geometric point, then

$$(f_*\underline{M})_{\bar{x}} = \bigoplus_{f(\bar{y})=\bar{x}} M$$

by Proposition 44.55.2 and similarly for the other sheaf. Since $Y' \rightarrow Y$ is surjective and finite we see that the induced map on geometric points lifting \bar{x} is surjective too and we conclude. \square

The lemma above will take care of higher cohomology groups in Gabber's result. The following lemma will be used to deal with global sections.

Lemma 44.74.7. *Let X be a quasi-compact and quasi-separated scheme. Let $i : Z \rightarrow X$ be a closed immersion. Assume that*

- (1) *for any sheaf \mathcal{F} on X_{Zar} the map $\Gamma(X, \mathcal{F}) \rightarrow \Gamma(Z, i^{-1}\mathcal{F})$ is bijective, and*
- (2) *for any finite morphism $X' \rightarrow X$ assumption (1) holds for $Z \times_X X' \rightarrow X'$.*

Then for any sheaf \mathcal{F} on $X_{\acute{e}tale}$ we have $\Gamma(X, \mathcal{F}) = \Gamma(Z, i_{small}^{-1}\mathcal{F})$.

Proof. Let \mathcal{F} be a sheaf on $X_{\acute{e}tale}$. There is a canonical (base change) map

$$i^{-1}(\mathcal{F}|_{X_{Zar}}) \longrightarrow (i_{small}^{-1}\mathcal{F})|_{Z_{Zar}}$$

of sheaves on Z_{Zar} . This map is injective as can be seen by looking on stalks. The stalk on the left hand side at $z \in Z$ is the stalk of $\mathcal{F}|_{X_{Zar}}$ at z . The stalk on the right hand side is the colimit over all elementary étale neighbourhoods $(U, u) \rightarrow (X, z)$ such that $U \times_X Z \rightarrow Z$ has a section over a neighbourhood of z . As étale morphisms are open, the image of $U \rightarrow X$ is an open neighbourhood of z in X and injectivity follows.

It follows from this and assumption (1) that the map $\Gamma(X, \mathcal{F}) \rightarrow \Gamma(Z, i_{small}^{-1}\mathcal{F})$ is injective. By (2) the same thing is true on all X' finite over X .

Let $s \in \Gamma(Z, i_{small}^{-1}\mathcal{F})$. By construction of $i_{small}^{-1}\mathcal{F}$ there exists an étale covering $\{V_j \rightarrow Z\}$, étale morphisms $U_j \rightarrow X$, sections $s_j \in \mathcal{F}(U_j)$ and morphisms $V_j \rightarrow U_j$ over X such that $s|_{V_j}$ is the pullback of s_j . Observe that every closed subscheme $T \subset X$ meets Z by assumption (1) applied to the sheaf $(T \rightarrow X)_*\underline{Z}$ for example. Thus we see that $\coprod U_j \rightarrow X$ is surjective. By More on Morphisms, Lemma 36.31.14 we can find a finite surjective morphism $X' \rightarrow X$ such that $X' \rightarrow X$ Zariski locally factors through $\coprod U_j \rightarrow X$. It follows that $s|_{Z'}$ Zariski locally comes from a section of $\mathcal{F}|_{X'}$. In other words, $s|_{Z'}$ comes from $t' \in \Gamma(X', \mathcal{F}|_{X'})$ by assumption (2). By injectivity we conclude that the two pullbacks of t' to $X' \times_X X'$ are the same (after all this is true for the pullbacks of s to $Z' \times_Z Z'$). Hence we conclude t' comes from a section of \mathcal{F} over X by Remark 44.55.5. \square

Lemma 44.74.8. *Let X be a topological space and let $Z \subset X$ be a closed subset. Suppose that for every $x \in X$ the intersection $Z \cap \overline{\{x\}}$ is connected (in particular nonempty). Then for any sheaf \mathcal{F} on X we have $\Gamma(X, \mathcal{F}) = \Gamma(Z, \mathcal{F}|_Z)$.*

Proof. Let's view a global section of \mathcal{F} as an assignment $x \mapsto s_x \in \mathcal{F}_x$ satisfying the continuity property (*) introduced in Sheaves, Section 6.17. If $x \rightsquigarrow z$ is a specialization on X , then there is a corresponding map on stalks $\mathcal{F}_z \rightarrow \mathcal{F}_x$. Thus, given a global section $s = (s_z)_{z \in Z}$ of $\mathcal{F}|_Z$ we can assign to every $x \in X$ a value s_x by choosing a $z \in Z \cap \overline{\{x\}}$ and taking the image of s_z . The fact that s_x is independent of the choice of z comes from the fact that we assumed $Z \cap \overline{\{x\}}$ is connected (details omitted). It is clear that this rule satisfies (*) and provides us with a section \tilde{s} of \mathcal{F} over X which restricts to s . \square

Lemma 44.74.9. *Let (A, I) be a henselian pair. Set $X = \text{Spec}(A)$ and $Z = \text{Spec}(A/I)$. For any sheaf \mathcal{F} on $X_{\acute{e}tale}$ we have $\Gamma(X, \mathcal{F}) = \Gamma(Z, \mathcal{F}|_Z)$.*

Proof. Combine Lemmas 44.74.7 and 44.74.8 and More on Algebra, Lemmas 15.7.9 and 15.7.11. \square

Finally, we can state and prove Gabber’s theorem.

Theorem 44.74.10 (Gabber). *Let (A, I) be a henselian pair. Set $X = \text{Spec}(A)$ and $Z = \text{Spec}(A/I)$. For any torsion abelian sheaf \mathcal{F} on $X_{\text{étale}}$ we have $H_{\text{étale}}^q(X, \mathcal{F}) = H_{\text{étale}}^q(Z, \mathcal{F}|_Z)$.*

Proof. The result holds for $q = 0$ by Lemma 44.74.9. Let $q \geq 1$. Suppose the result has been shown in all degrees $< q$. Let \mathcal{F} be a torsion abelian sheaf. Let $\mathcal{F} \rightarrow \mathcal{F}'$ be an injective map of torsion abelian sheaves (to be chosen later) with cokernel \mathcal{Q} so that we have the short exact sequence

$$0 \rightarrow \mathcal{F} \rightarrow \mathcal{F}' \rightarrow \mathcal{Q} \rightarrow 0$$

of torsion abelian sheaves on $X_{\text{étale}}$. This gives a map of long exact cohomology sequences over X and Z part of which looks like

$$\begin{array}{ccccccc} H_{\text{étale}}^{q-1}(X, \mathcal{F}') & \longrightarrow & H_{\text{étale}}^{q-1}(X, \mathcal{Q}) & \longrightarrow & H_{\text{étale}}^q(X, \mathcal{F}) & \longrightarrow & H_{\text{étale}}^q(X, \mathcal{F}') \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ H_{\text{étale}}^{q-1}(Z, \mathcal{F}'|_Z) & \longrightarrow & H_{\text{étale}}^{q-1}(Z, \mathcal{Q}|_Z) & \longrightarrow & H_{\text{étale}}^q(Z, \mathcal{F}|_Z) & \longrightarrow & H_{\text{étale}}^q(Z, \mathcal{F}'|_Z) \end{array}$$

Using this commutative diagram of abelian groups with exact rows we will finish the proof.

Injectivity for \mathcal{F} . Let ξ be a nonzero element of $H_{\text{étale}}^q(X, \mathcal{F})$. By Lemma 44.74.6 applied with $Z = X$ (!) we can find $\mathcal{F} \subset \mathcal{F}'$ such that ξ maps to zero to the right. Then ξ is the image of an element of $H_{\text{étale}}^{q-1}(X, \mathcal{Q})$ and bijectivity for $q - 1$ implies ξ does not map to zero in $H_{\text{étale}}^q(Z, \mathcal{F}|_Z)$.

Surjectivity for \mathcal{F} . Let ξ be an element of $H_{\text{étale}}^q(Z, \mathcal{F}|_Z)$. By Lemma 44.74.6 applied with $Z = Z$ we can find $\mathcal{F} \subset \mathcal{F}'$ such that ξ maps to zero to the right. Then ξ is the image of an element of $H_{\text{étale}}^{q-1}(Z, \mathcal{Q}|_Z)$ and bijectivity for $q - 1$ implies ξ is in the image of the vertical map. \square

Lemma 44.74.11. *Let (A, I) be a henselian pair. Set $X = \text{Spec}(A)$ and $Z = \text{Spec}(A/I)$. The functor*

$$U \longmapsto U \times_X Z$$

is an equivalence of categories between finite étale schemes over X and finite étale schemes over Z .

Proof. This is a translation of More on Algebra, Lemma 15.7.12. \square

Lemma 44.74.12. *Let X be a scheme with affine diagonal which can be covered by $n + 1$ affine opens. Let $Z \subset X$ be a closed subscheme. Let \mathcal{A} be a torsion sheaf of rings on $X_{\text{étale}}$ and let \mathcal{I} be an injective sheaf of \mathcal{A} -modules on $X_{\text{étale}}$. Then $H_{\text{étale}}^q(Z, \mathcal{I}|_Z) = 0$ for $q > n$.*

Proof. We will prove this by induction on n . If $n = 0$, then X is affine. Say $X = \text{Spec}(A)$ and $Z = \text{Spec}(A/I)$. Let A^h be the filtered colimit of étale A -algebras B such that $A/I \rightarrow B/IB$ is an isomorphism. Then (A^h, IA^h) is a henselian pair

and $A/I = A^h/IA^h$, see More on Algebra, Lemma 15.7.13 and its proof. Set $X^h = \text{Spec}(A^h)$. By Theorem 44.74.10 we see that

$$H_{\text{étale}}^q(Z, \mathcal{I}|_Z) = H_{\text{étale}}^q(X^h, \mathcal{I}|_{X^h})$$

By Theorem 44.52.1 we have

$$H_{\text{étale}}^q(X^h, \mathcal{F}|_{X^h}) = \text{colim}_{A \rightarrow B} H_{\text{étale}}^q(\text{Spec}(B), \mathcal{I}|_{\text{Spec}(B)})$$

where the colimit is over the A -algebras B as above. Since the morphisms $\text{Spec}(B) \rightarrow \text{Spec}(A)$ are étale, the restriction $\mathcal{I}|_{\text{Spec}(B)}$ is an injective sheaf of $\mathcal{A}|_{\text{Spec}(B)}$ -modules (Cohomology on Sites, Lemma 21.8.1). Thus the cohomology groups on the right are zero and we get the result in this case.

Induction step. We can use Mayer-Vietoris to do the induction step. Namely, suppose that $X = U \cup V$ where U is a union of n affine opens and V is affine. Then, using that the diagonal of X is affine, we see that $U \cap V$ is the union of n affine opens. Mayer-Vietoris gives an exact sequence

$$H_{\text{étale}}^{q-1}(U \cap V \cap Z, \mathcal{F}|_Z) \rightarrow H_{\text{étale}}^q(Z, \mathcal{I}|_Z) \rightarrow H_{\text{étale}}^q(U \cap Z, \mathcal{F}|_Z) \oplus H_{\text{étale}}^q(V \cap Z, \mathcal{F}|_Z)$$

and by our induction hypothesis we obtain vanishing for $q > n$ as desired. \square

44.75. Cohomology of torsion sheaves on curves

The goal of this section is to prove Theorem 44.75.12. The proof uses the “méthode de la trace” as explained in [AGV71, Exposé IX, §5].

Let $f : Y \rightarrow X$ be an étale morphism of schemes. There are pairs of adjoint functors $(f_!, f^{-1})$ and (f^{-1}, f_*) between $Ab(X_{\text{étale}})$ and $Ab(Y_{\text{étale}})$. The adjunction map $\text{id} \rightarrow f_* f^{-1}$ is called *restriction*. The adjunction map $f_* f^{-1} = f_! f^{-1} \rightarrow \text{id}$ is often called the *trace map*. If f is finite, then $f_* = f_!$ and we can view this as a map $f_* f^{-1} \rightarrow \text{id}$.

Definition 44.75.1. Let $f : Y \rightarrow X$ be a finite étale morphism of schemes. The map $f_* f^{-1} \rightarrow \text{id}$ described above is called the *trace*.

Let $f : Y \rightarrow X$ be a finite étale morphism. The trace map is characterized by the following two properties:

- (1) it commutes with étale localization and
- (2) if $Y = \coprod_{i=1}^d X$ then the trace map is the sum map $f_* f^{-1} \mathcal{F} = \mathcal{F}^{\oplus d} \rightarrow \mathcal{F}$.

It follows that if f has constant degree d , then the composition

$$\mathcal{F} \xrightarrow{\text{res}} f_* f^{-1} \mathcal{F} \xrightarrow{\text{trace}} \mathcal{F}$$

is multiplication by d . An example of the “méthode de la trace” is the following observation: if \mathcal{F} is an abelian sheaf on $X_{\text{étale}}$ such that multiplication by d is an isomorphism $\mathcal{F} \cong \mathcal{F}$, and if furthermore $H_{\text{étale}}^q(Y, f^{-1} \mathcal{F}) = 0$ then $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ as well. Indeed, multiplication by d induces an isomorphism on $H_{\text{étale}}^q(X, \mathcal{F})$ which factors through $H_{\text{étale}}^q(Y, f^{-1} \mathcal{F}) = 0$. This will be used in the proof of Lemma 44.75.11 below.

Situation 44.75.2. Here k is an algebraically closed field, X is a separated, finite type scheme of dimension ≤ 1 over k , and \mathcal{F} is a torsion abelian sheaf on $X_{\text{étale}}$.

In Situation 44.75.2 we want to prove the following statements

- (1) $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ for $q > 2$,

- (2) $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ for $q > 1$ if X is affine,
- (3) $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ for $q > 1$ if $p = \text{char}(k) > 0$ and \mathcal{F} is p -power torsion,
- (4) $H_{\text{étale}}^q(X, \mathcal{F})$ is finite if \mathcal{F} is constructible and torsion prime to $\text{char}(k)$,
- (5) $H_{\text{étale}}^q(X, \mathcal{F})$ is finite if X is proper and \mathcal{F} constructible,
- (6) $H_{\text{étale}}^q(X, \mathcal{F}) \rightarrow H_{\text{étale}}^q(X_{k'}, \mathcal{F}|_{X_{k'}})$ is an isomorphism for any extension $k \subset k'$ of algebraically closed fields if \mathcal{F} is torsion prime to $\text{char}(k)$,
- (7) $H_{\text{étale}}^q(X, \mathcal{F}) \rightarrow H_{\text{étale}}^q(X_{k'}, \mathcal{F}|_{X_{k'}})$ is an isomorphism for any extension $k \subset k'$ of algebraically closed fields if X is proper,
- (8) $H_{\text{étale}}^2(X, \mathcal{F}) \rightarrow H_{\text{étale}}^2(U, \mathcal{F})$ is surjective for all $U \subset X$ open.

Given any Situation 44.75.2 we will say that “statements (1) – (8) hold” if those statements that apply to the given situation are true. We start the proof with the following consequence of our computation of cohomology with constant coefficients.

Lemma 44.75.3. *In Situation 44.75.2 assume X is smooth and $\mathcal{F} = \underline{\mathbf{Z}/\ell\mathbf{Z}}$ for some prime number ℓ . Then statements (1) – (8) hold for \mathcal{F} .*

Proof. Since X is smooth, we see that X is a finite disjoint union of smooth curves. Hence we may assume X is a smooth curve.

Case I: ℓ different from the characteristic of k . This case follows from Lemma 44.66.3 (projective case) and Lemma 44.66.5 (affine case). Statement (6) on cohomology and extension of algebraically closed ground field follows from the fact that the genus g and the number of “punctures” r do not change when passing from k to k' . Statement (8) follows as $H_{\text{étale}}^2(U, \mathcal{F})$ is zero as soon as $U \neq X$, because then U is affine (Varieties, Lemmas 32.23.2 and 32.23.5).

Case II: ℓ is equal to the characteristic of k . Vanishing by Lemma 44.65.4. Statements (5) and (7) follow from Lemma 44.65.5. □

Remark 44.75.4 (Invariance under extension of algebraically closed ground field). Let k be an algebraically closed field of characteristic $p > 0$. In Section 44.65 we have seen that there is an exact sequence

$$k[x] \rightarrow k[x] \rightarrow H_{\text{étale}}^1(\mathbf{A}_k^1, \mathbf{Z}/p\mathbf{Z}) \rightarrow 0$$

where the first arrow maps $f(x)$ to $f^p - f$. A set of representatives for the cokernel is formed by the polynomials

$$\sum_{p \nmid n} \lambda_n x^n$$

with $\lambda_n \in k$. (If k is not algebraically closed you have to add some constants to this as well.) In particular when $k' \supset k$ is an algebraically closed overfield, then the map

$$H_{\text{étale}}^1(\mathbf{A}_k^1, \mathbf{Z}/p\mathbf{Z}) \rightarrow H_{\text{étale}}^1(\mathbf{A}_{k'}^1, \mathbf{Z}/p\mathbf{Z})$$

is not an isomorphism in general. In particular, the map $\pi_1(\mathbf{A}_{k'}^1) \rightarrow \pi_1(\mathbf{A}_k^1)$ between étale fundamental groups (insert future reference here) is not an isomorphism either. Thus the étale homotopy type of the affine line depends on the algebraically closed ground field. From Lemma 44.75.3 above we see that this is a phenomenon which only happens in characteristic p with p -power torsion coefficients.

Lemma 44.75.5. *Let k be an algebraically closed field. Let X be a separated finite type scheme over k of dimension ≤ 1 . Let $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F} \rightarrow \mathcal{F}_2 \rightarrow 0$ be a short exact sequence of torsion abelian sheaves on X . If statements (1) – (8) hold for \mathcal{F}_1 and \mathcal{F}_2 , then they hold for \mathcal{F} .*

Proof. This is mostly immediate from the definitions and the long exact sequence of cohomology. Also observe that \mathcal{F} is constructible (resp. of torsion prime to the characteristic of k) if and only if both \mathcal{F}_1 and \mathcal{F}_2 are constructible (resp. of torsion prime to the characteristic of k). See Proposition 44.72.1. Some details omitted. \square

Lemma 44.75.6. *Let k be an algebraically closed field. Let $f : X \rightarrow Y$ be a finite morphism of separated finite type schemes over k of dimension ≤ 1 . Let \mathcal{F} be a torsion abelian sheaf on X . If statements (1) – (8) hold for \mathcal{F} , then they hold for $f_*\mathcal{F}$.*

Proof. Follows from the vanishing of the higher direct images $R^q f_*$ (Proposition 44.55.2), the Leray spectral sequence (Proposition 44.54.2), and the fact that formation of f_* commutes with arbitrary base change (Lemma 44.55.3). \square

Lemma 44.75.7. *In Situation 44.75.2 assume X is smooth. Let $j : U \rightarrow X$ an open immersion. Let ℓ be a prime number. Let $\mathcal{F} = j_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$. Then statements (1) – (8) hold for \mathcal{F} .*

Proof. Consider the short exact sequence

$$0 \rightarrow j_! \underline{\mathbf{Z}/\ell\mathbf{Z}}_U \rightarrow \underline{\mathbf{Z}/\ell\mathbf{Z}}_X \rightarrow \bigoplus_{x \in X \setminus U} i_{x*}(\underline{\mathbf{Z}/\ell\mathbf{Z}}) \rightarrow 0.$$

Statements (1) – (8) hold for $\underline{\mathbf{Z}/\ell\mathbf{Z}}$ by Lemma 44.75.3. Since the inclusion morphisms $i_x : x \rightarrow X$ are finite and since x is the spectrum of an irreducible curve, we see that $H_{\text{étale}}^q(X, i_{x*} \underline{\mathbf{Z}/\ell\mathbf{Z}})$ is zero for $q > 0$ and equal to $\underline{\mathbf{Z}/\ell\mathbf{Z}}$ for $q = 0$. Thus we get from the long exact cohomology sequence

$$\begin{array}{ccccccc} 0 & \longrightarrow & H_{\text{étale}}^0(X, \mathcal{F}) & \longrightarrow & H^0(X, \underline{\mathbf{Z}/\ell\mathbf{Z}}_X) & \longrightarrow & \bigoplus_{x \in X \setminus U} \underline{\mathbf{Z}/\ell\mathbf{Z}} \\ & & & & & & \swarrow \\ & & & & & & H_{\text{étale}}^1(X, \mathcal{F}) \longrightarrow H_{\text{étale}}^1(X, \underline{\mathbf{Z}/\ell\mathbf{Z}}_X) \longrightarrow 0 \end{array}$$

and $H_{\text{étale}}^q(X, \mathcal{F}) = H_{\text{étale}}^q(X, \underline{\mathbf{Z}/\ell\mathbf{Z}}_X)$ for $q \geq 2$. Each of the statements (1) – (8) follows by inspection. \square

Lemma 44.75.8. *In Situation 44.75.2 assume X reduced. Let $j : U \rightarrow X$ an open immersion. Let ℓ be a prime number and $\mathcal{F} = j_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$. Then statements (1) – (8) hold for \mathcal{F} .*

Proof. The difference with Lemma 44.75.7 is that here we do not assume X is smooth. Let $\nu : X' \rightarrow X$ be the normalization morphism which is finite as varieties are Nagata schemes. Let $j' : U' \rightarrow X'$ be the inverse image of U . By Lemma 44.75.7 the result holds for $j'_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$. By Lemma 44.75.6 the result holds for $\nu_* j'_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$. In general it won't be true that $\nu_* j'_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$ is equal to $j_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$, but there will be a canonical injective map

$$j_! \underline{\mathbf{Z}/\ell\mathbf{Z}} \rightarrow \nu_* j'_! \underline{\mathbf{Z}/\ell\mathbf{Z}}$$

whose cokernel is of the form $\bigoplus_{x \in Z} i_{x*} M_x$ where $Z \subset X$ is a finite set of closed points and M_x is a finite dimensional \mathbf{F}_ℓ -vector space for each $x \in Z$. We obtain a short exact sequence

$$0 \rightarrow j_! \underline{\mathbf{Z}/\ell\mathbf{Z}} \rightarrow \nu_* j'_! \underline{\mathbf{Z}/\ell\mathbf{Z}} \rightarrow \bigoplus_{x \in Z} i_{x*} M_x \rightarrow 0$$

and we can argue exactly as in the proof of Lemma 44.75.7 to finish the argument. Some details omitted. \square

Exercise 44.75.9. Let $f : X \rightarrow Y$ be a finite étale morphism with X and Y irreducible. Then there exists a finite étale Galois morphism $X' \rightarrow Y$ which dominates X over Y .

Lemma 44.75.10. *Let S be an irreducible scheme. Let ℓ be a prime number. Let \mathcal{F} a finite locally constant sheaf of \mathbf{F}_ℓ -vector spaces on $S_{\text{étale}}$. There exists a finite étale morphism $f : T \rightarrow S$ of degree prime to ℓ such that $f^{-1}\mathcal{F}$ has a finite filtration whose successive quotients are $\underline{\mathbf{Z}}/\ell\underline{\mathbf{Z}}_T$.*

Proof. Since \mathcal{F} is finite locally constant and S irreducible, we see that \mathcal{F} has constant rank r . Let $T \rightarrow S$ be a finite étale covering such that $f^{-1}\mathcal{F}$ is isomorphic to $\underline{\mathbf{Z}}/\ell\underline{\mathbf{Z}}^{\oplus r}$. We may assume T is irreducible and $T \rightarrow S$ is Galois with group G . This means simply that we have $G \subset \text{Aut}(T/S)$ and that G maps isomorphically to the Galois group of the field extension in the generic points. Observe that the action of G on T lifts to an action of G on $f^{-1}\mathcal{F} \cong \underline{\mathbf{Z}}/\ell\underline{\mathbf{Z}}^{\oplus r}$. Looking at the stalk in the generic point we obtain a representation $\rho : \bar{G} \rightarrow \text{GL}_r(\mathbf{F}_\ell)$. Let $H \subset G$ be an ℓ -Sylow subgroup. We claim that $T/H \rightarrow S$ works. Namely, since H is a finite ℓ -group, the irreducible constituents of the representation $\rho|_H$ are each trivial of rank 1. Moreover the degree of $T/H \rightarrow S$ is prime to ℓ . Some details omitted. \square

Lemma 44.75.11. *In Situation 44.75.2 assume X reduced. Let $j : U \rightarrow X$ an open immersion with U irreducible. Let ℓ be a prime number. Let \mathcal{G} a finite locally constant sheaf of \mathbf{F}_ℓ -vector spaces on U . Let $\mathcal{F} = j_*\mathcal{G}$. Then statements (1) – (8) hold for \mathcal{F} .*

Proof. Let $f : V \rightarrow U$ be a finite étale morphism of degree prime to ℓ as in Lemma 44.75.10. The trace map gives maps

$$\mathcal{G} \rightarrow f_*f^{-1}\mathcal{G} \rightarrow \mathcal{F}$$

whose composition is an isomorphism. Hence it suffices to prove the lemma with $\mathcal{F} = j_*f_*f^{-1}\mathcal{G}$. By Zariski’s Main theorem (More on Morphisms, Lemma 36.31.3) we can choose a diagram

$$\begin{array}{ccc} V & \xrightarrow{j'} & Y \\ f \downarrow & & \downarrow \bar{f} \\ U & \xrightarrow{j} & X \end{array}$$

with $\bar{f} : Y \rightarrow X$ finite and j' an open immersion with dense image. Since f is finite this implies that $V = U \times_X Y$. Hence $j_*f_*f^{-1}\mathcal{G} = \bar{f}_*j'_*f^{-1}\mathcal{G}$ by Lemma 44.55.3. By Lemma 44.75.6 it suffices to prove the lemma for $j'_*f^{-1}\mathcal{G}$. The existence of the filtration given by Lemma 44.75.10, the fact that j'_* is exact, and Lemma 44.75.5 reduces us to the case $\mathcal{F} = j'_*\underline{\mathbf{Z}}/\ell\underline{\mathbf{Z}}$ which is Lemma 44.75.8. \square

Theorem 44.75.12. *If k is an algebraically closed field, X is a separated, finite type scheme of dimension ≤ 1 over k , and \mathcal{F} is a torsion abelian sheaf on $X_{\text{étale}}$, then*

- (1) $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ for $q > 2$,
- (2) $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ for $q > 1$ if X is affine,
- (3) $H_{\text{étale}}^q(X, \mathcal{F}) = 0$ for $q > 1$ if $p = \text{char}(k) > 0$ and \mathcal{F} is p -power torsion,

- (4) $H_{\acute{e}tale}^q(X, \mathcal{F})$ is finite if \mathcal{F} is constructible and torsion prime to $\text{char}(k)$,
- (5) $H_{\acute{e}tale}^q(X, \mathcal{F})$ is finite if X is proper and \mathcal{F} constructible,
- (6) $H_{\acute{e}tale}^q(X, \mathcal{F}) \rightarrow H_{\acute{e}tale}^q(X_{k'}, \mathcal{F}|_{X_{k'}})$ is an isomorphism for any extension $k \subset k'$ of algebraically closed fields if \mathcal{F} is torsion prime to $\text{char}(k)$,
- (7) $H_{\acute{e}tale}^q(X, \mathcal{F}) \rightarrow H_{\acute{e}tale}^q(X_{k'}, \mathcal{F}|_{X_{k'}})$ is an isomorphism for any extension $k \subset k'$ of algebraically closed fields if X is proper,
- (8) $H_{\acute{e}tale}^2(X, \mathcal{F}) \rightarrow H_{\acute{e}tale}^2(U, \mathcal{F})$ is surjective for all $U \subset X$ open.

Proof. The theorem says that in Situation 44.75.2 statements (1) – (8) hold. Our first step is to replace X by its reduction, which is permissible by Proposition 44.46.3. By Lemma 44.71.2 we can write \mathcal{F} as a filtered colimit of constructible abelian sheaves. Taking cohomology commutes with colimits, see Lemma 44.52.2. Moreover, pullback via $X_{k'} \rightarrow X$ commutes with colimits as a left adjoint. Thus it suffices to prove the statements for a constructible sheaf.

In this paragraph we use Lemma 44.75.5 without further mention. Writing $\mathcal{F} = \mathcal{F}_1 \oplus \dots \oplus \mathcal{F}_r$ where \mathcal{F}_i is ℓ_i -primary for some prime ℓ_i , we may assume that ℓ^n kills \mathcal{F} for some prime ℓ . Now consider the exact sequence

$$0 \rightarrow \mathcal{F}[\ell] \rightarrow \mathcal{F} \rightarrow \mathcal{F}/\mathcal{F}[\ell] \rightarrow 0.$$

Thus we see that it suffices to assume that \mathcal{F} is ℓ -torsion. This means that \mathcal{F} is a constructible sheaf of \mathbf{F}_ℓ -vector spaces for some prime number ℓ .

By definition this means there is a dense open $U \subset X$ such that $\mathcal{F}|_U$ is finite locally constant sheaf of \mathbf{F}_ℓ -vector spaces. Since $\dim(X) \leq 1$ we may assume, after shrinking U , that $U = U_1 \amalg \dots \amalg U_n$ is a disjoint union of irreducible schemes (just remove the closed points which lie in the intersections of ≥ 2 components of U). Consider the short exact sequence

$$0 \rightarrow j_!j^{-1}\mathcal{F} \rightarrow \mathcal{F} \rightarrow \bigoplus_{x \in Z} i_{x*}M_x \rightarrow 0$$

where $Z = X \setminus U$ and M_x is a finite dimensional \mathbf{F}_ℓ vector space, see Lemma 44.67.6. Since the étale cohomology of $i_{x*}M_x$ vanishes in degrees ≥ 1 and is equal to M_x in degree 0 it suffices to prove the theorem for $j_!j^{-1}\mathcal{F}$ (argue exactly as in the proof of Lemma 44.75.7). Thus we reduce to the case $\mathcal{F} = j_!\mathcal{G}$ where \mathcal{G} is a finite locally constant sheaf of \mathbf{F}_ℓ -vector spaces on U .

Since we chose $U = U_1 \amalg \dots \amalg U_n$ with U_i irreducible we have

$$j_!\mathcal{G} = j_{1!}(\mathcal{G}|_{U_1}) \oplus \dots \oplus j_{n!}(\mathcal{G}|_{U_n})$$

where $j_i : U_i \rightarrow X$ is the inclusion morphism. The case of $j_{i!}(\mathcal{G}|_{U_i})$ is handled in Lemma 44.75.11. □

Remarks 44.75.13. The “trace method” is very general. For instance, it applies in Galois cohomology, and this is essentially how Proposition 44.63.1 is proved.

Theorem 44.75.14. *Let X be a finite type, dimension 1 scheme over an algebraically closed field k . Let \mathcal{F} be a torsion sheaf on $X_{\acute{e}tale}$. Then*

$$H_{\acute{e}tale}^q(X, \mathcal{F}) = 0, \quad \forall q \geq 3.$$

If X affine then also $H_{\acute{e}tale}^2(X, \mathcal{F}) = 0$.

Proof. If X is separated, this follows immediately from the more precise Theorem 44.75.12. If X is nonseparated, choose an affine open covering $X = X_1 \cup \dots \cup X_n$. By induction on n we may assume the vanishing holds over $U = X_1 \cup \dots \cup X_{n-1}$. Then Mayer-Vietoris (Lemma 44.51.1) gives

$$H_{\acute{e}tale}^2(U, \mathcal{F}) \oplus H_{\acute{e}tale}^2(X_n, \mathcal{F}) \rightarrow H_{\acute{e}tale}^2(U \cap X_n, \mathcal{F}) \rightarrow H_{\acute{e}tale}^3(X, \mathcal{F}) \rightarrow 0$$

However, since $U \cap X_n$ is an open of an affine scheme and hence affine by our dimension assumption, the group $H_{\acute{e}tale}^2(U \cap X_n, \mathcal{F})$ vanishes by Theorem 44.75.12. \square

Lemma 44.75.15. *Let $k \subset k'$ be an extension of separably closed fields. Let X be a proper scheme over k of dimension ≤ 1 . Let \mathcal{F} be a torsion abelian sheaf on X . Then the map $H_{\acute{e}tale}^q(X, \mathcal{F}) \rightarrow H_{\acute{e}tale}^q(X_{k'}, \mathcal{F}|_{X_{k'}})$ is an isomorphism for $q \geq 0$.*

Proof. We have seen this for algebraically closed fields in Theorem 44.75.12. Given $k \subset k'$ as in the statement of the lemma we can choose a diagram

$$\begin{array}{ccc} k' & \longrightarrow & \bar{k}' \\ \uparrow & & \uparrow \\ k & \longrightarrow & \bar{k} \end{array}$$

where $k \subset \bar{k}$ and $k' \subset \bar{k}'$ are the algebraic closures. Since k and k' are separably closed the field extensions $k \subset \bar{k}$ and $k' \subset \bar{k}'$ are algebraic and purely inseparable. In this case the morphisms $X_{\bar{k}} \rightarrow X$ and $X_{\bar{k}'} \rightarrow X_{k'}$ are universal homeomorphisms. Thus the cohomology of \mathcal{F} may be computed on $X_{\bar{k}}$ and the cohomology of $\mathcal{F}|_{X_{k'}}$ may be computed on $X_{\bar{k}'}$, see Proposition 44.46.3. Hence we deduce the general case from the case of algebraically closed fields. \square

44.76. Finite étale covers of proper schemes

The results in this section in some sense say that taking $R^1 f_* \underline{G}$ commute with base change if $f : X \rightarrow Y$ is a proper morphism and G is a finite group.

Lemma 44.76.1. *Let A be a henselian local ring. Let X be a proper scheme over A with closed fibre X_0 . Then the functor*

$$U \longmapsto U_0 = U \times_X X_0$$

is an equivalence of categories between schemes finite étale over X and schemes finite étale over X_0 .

Proof. The proof given here is an example of applying algebraization and approximation. We proceed in a number of stages.

Essential surjectivity when A is a complete local Noetherian ring. Let $X_n = X \times_{\text{Spec}(A)} \text{Spec}(A/\mathfrak{m}^{n+1})$. By Proposition 44.46.3 the inclusions

$$X_0 \rightarrow X_1 \rightarrow X_2 \rightarrow \dots$$

induce equivalence of categories between small étale sites. Moreover, if $U_n \rightarrow X_n$ corresponds to a finite étale morphism $U_0 \rightarrow X_0$, then $U_n \rightarrow X_n$ is finite too, for example by More on Morphisms, Lemma 36.2.6. In this case the morphism $U_0 \rightarrow \text{Spec}(A/\mathfrak{m})$ is proper as X_0 is proper over A/\mathfrak{m} . Thus we may apply Grothendieck's algebraization theorem (in the form of Cohomology of Schemes, Lemma 29.23.2)

to see that there is a finite morphism $U \rightarrow X$ whose restriction to X_0 recovers U_0 . By More on Morphisms, Lemma 36.10.3 we see that $U \rightarrow X$ is étale at every point of U_0 . However, since every point of U specializes to a point of U_0 (as U is proper over A), we conclude that $U \rightarrow X$ is étale. In this way we conclude the functor is essentially surjective.

Fully faithfulness when A is a complete local Noetherian ring. Let $U \rightarrow X$ and $V \rightarrow X$ be finite étale morphisms and let $\varphi_0 : U_0 \rightarrow V_0$ be a morphism over X_0 . Look at the morphism

$$\Gamma_{\varphi_0} : U_0 \longrightarrow U_0 \times_{X_0} V_0$$

This morphism is both finite étale and a closed immersion. By essential surjectivity applied to $X = U \times_X V$ we find a finite étale morphism $W \rightarrow U \times_X V$ whose special fibre is isomorphic to Γ_{φ_0} . Consider the projection $W \rightarrow U$. It is finite étale and an isomorphism over U_0 by construction. By Étale Morphisms, Lemma 40.14.2 $W \rightarrow U$ is an isomorphism in an open neighbourhood of U_0 . Thus it is an isomorphism and the composition $\varphi : U \cong W \rightarrow V$ is the desired lift of φ_0 .

Essential surjectivity when A is a henselian local Noetherian G-ring. Let $U_0 \rightarrow X_0$ be a finite étale morphism. Let A^\wedge be the completion of A with respect to the maximal ideal. Let X^\wedge be the base change of X to A^\wedge . By the result above there exists a finite étale morphism $V \rightarrow X^\wedge$ whose special fibre is U_0 . Write $A^\wedge = \text{colim } A_i$ with $A \rightarrow A_i$ of finite type. By Limits, Lemma 31.9.1 there exists an i and a finitely presented morphism $U_i \rightarrow X_{A_i}$ whose base change to X^\wedge is V . After increasing i we may assume that $U_i \rightarrow X_{A_i}$ is finite and étale (Limits, Lemmas 31.7.3 and 31.7.8). Writing

$$A_i = A[x_1, \dots, x_n]/(f_1, \dots, f_m)$$

the ring map $A_i \rightarrow A^\wedge$ can be reinterpreted as a solution (a_1, \dots, a_n) in A^\wedge for the system of equations $f_j = 0$. By Smoothing Ring Maps, Theorem 16.13.1 we can approximate this solution (to order 11 for example) by a solution (b_1, \dots, b_n) in A . Translating back we find an A -algebra map $A_i \rightarrow A$ which gives the same closed point as the original map $A_i \rightarrow A^\wedge$ (as $11 > 1$). The base change $U \rightarrow X$ of $V \rightarrow X_{A_i}$ by this ring map will therefore be a finite étale morphism whose special fibre is isomorphic to U_0 .

Fully faithfulness when A is a henselian local Noetherian G-ring. This can be deduced from essential surjectivity in exactly the same manner as was done in the case that A is complete Noetherian.

General case. Let (A, \mathfrak{m}) be a henselian local ring. Set $S = \text{Spec}(A)$ and denote $s \in S$ the closed point. By Limits, Lemma 31.12.6 we can write $X \rightarrow \text{Spec}(A)$ as a cofiltered limit of proper morphisms $X_i \rightarrow S_i$ with S_i of finite type over \mathbf{Z} . For each i let $s_i \in S_i$ be the image of s . Since $S = \lim S_i$ and $A = \mathcal{O}_{S,s}$ we have $A = \text{colim } \mathcal{O}_{S_i, s_i}$. The ring $A_i = \mathcal{O}_{S_i, s_i}$ is a Noetherian local G-ring (More on Algebra, Proposition 15.39.12). By More on Algebra, Lemma 15.7.17 we see that $A = \text{colim } A_i^h$. By More on Algebra, Lemma 15.39.8 the rings A_i^h are G-rings. Thus we see that $A = \text{colim } A_i^h$ and

$$X = \lim(X_i \times_{S_i} \text{Spec}(A_i^h))$$

as schemes. The category of schemes finite étale over X is the limit of the category of schemes finite étale over $X_i \times_{S_i} \text{Spec}(A_i^h)$ (by Limits, Lemmas 31.9.1, 31.7.3, and

31.7.8) The same thing is true for schemes finite étale over $X_0 = \lim(X_i \times_{S_i} s_i)$. Thus we formally deduce the result for $X/\mathrm{Spec}(A)$ from the result for the $(X_i \times_{S_i} \mathrm{Spec}(A_i^h))/\mathrm{Spec}(A_i^h)$ which we dealt with above. \square

Lemma 44.76.2. *Let $k \subset k'$ be an extension of algebraically closed fields. Let X be a proper scheme over k . Then the functor*

$$U \longmapsto U_{k'}$$

is an equivalence of categories between schemes finite étale over X and schemes finite étale over $X_{k'}$.

Proof. Let us prove the functor is essentially surjective. Let $U' \rightarrow X_{k'}$ be a finite étale morphism. Write $k' = \mathrm{colim} A_i$ as a filtered colimit of finite type k -algebras. By Limits, Lemma 31.9.1 there exists an i and a finitely presented morphism $U_i \rightarrow X_{A_i}$ whose base change to $X_{k'}$ is U' . After increasing i we may assume that $U_i \rightarrow X_{A_i}$ is finite and étale (Limits, Lemmas 31.7.3 and 31.7.8). Since k is algebraically closed we can find a k -valued point t in $\mathrm{Spec}(A_i)$. Let $U = (U_i)_t$ be the fibre of U_i over t . Let A_i^h be the henselization of $(A_i)_{\mathfrak{m}}$ where \mathfrak{m} is the maximal ideal corresponding to the point t . By Lemma 44.76.1 we see that $(U_i)_{A_i^h} = U \times \mathrm{Spec}(A_i^h)$ as schemes over $X_{A_i^h}$. Now since A_i^h is algebraic over A_i (see for example discussion in Smoothing Ring Maps, Example 16.13.3) and since k' is algebraically closed we can find a ring map $A_i^h \rightarrow k'$ extending the given inclusion $A_i \subset k'$. Hence we conclude that U' is isomorphic to the base change of U . The proof of fully faithfulness is exactly the same. \square

Lemma 44.76.3. *Let A be a henselian local ring. Let X be a proper scheme over A with closed fibre X_0 . Let M be a finite abelian group. Then $H_{\acute{e}tale}^1(X, \underline{M}) = H_{\acute{e}tale}^1(X_0, \underline{M})$.*

Proof. By Cohomology on Sites, Lemma 21.5.3 an element of $H_{\acute{e}tale}^1(X, \underline{M})$ corresponds to a \underline{M} -torsor \mathcal{F} on $X_{\acute{e}tale}$. Such a torsor is clearly a finite locally constant sheaf. Hence \mathcal{F} is representable by a scheme V finite étale over X , Lemma 44.68.4. Conversely, a scheme V finite étale over X with an M -action which turns it into an M -torsor over X gives rise to a cohomology class. The same translation between cohomology classes over X_0 and torsors finite étale over X_0 holds. Thus the lemma is a consequence of the equivalence of categories of Lemma 44.76.1. \square

The following technical lemma is a key ingredient in the proof of the proper base change theorem. The argument can be made to work for any proper scheme over A whose special fibre has dimension ≤ 1 , but in fact the conclusion will be a consequence of the proper base change theorem and we only need this particular version in its proof.

Lemma 44.76.4. *Let A be a henselian local ring. Let $X = \mathbf{P}_A^1$. Let $X_0 \subset X$ be the closed fibre. Let ℓ be a prime number. Let \mathcal{I} be an injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $X_{\acute{e}tale}$. Then $H_{\acute{e}tale}^q(X_0, \mathcal{I}|_{X_0}) = 0$ for $q > 0$.*

Proof. Observe that X is a separated scheme which can be covered by 2 affine opens. Hence for $q > 1$ this follows from Gabber's affine variant of the proper base change theorem, see Lemma 44.74.12. Thus we may assume $q = 1$. Let $\xi \in H_{\acute{e}tale}^1(X_0, \mathcal{I}|_{X_0})$. Goal: show that ξ is 0. By Lemmas 44.71.2 and 44.52.2 we can find a map $\mathcal{F} \rightarrow \mathcal{I}$ with \mathcal{F} a constructible sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules and ξ coming

from an element ζ of $H^1_{\text{étale}}(X_0, \mathcal{F}|_{X_0})$. Suppose we have an injective map $\mathcal{F} \rightarrow \mathcal{F}'$ of sheaves of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $X_{\text{étale}}$. Since \mathcal{I} is injective we can extend the given map $\mathcal{F} \rightarrow \mathcal{I}$ to a map $\mathcal{F}' \rightarrow \mathcal{I}$. In this situation we may replace \mathcal{F} by \mathcal{F}' and ζ by the image of ζ in $H^1_{\text{étale}}(X_0, \mathcal{F}'|_{X_0})$. Also, if $\mathcal{F} = \mathcal{F}_1 \oplus \mathcal{F}_2$ is a direct sum, then we may replace \mathcal{F} by \mathcal{F}_i and ζ by the image of ζ in $H^1_{\text{étale}}(X_0, \mathcal{F}_i|_{X_0})$.

By Lemma 44.72.4 and the remarks above we may assume \mathcal{F} is of the form $f_*\underline{M}$ where M is a finite $\mathbf{Z}/\ell\mathbf{Z}$ -module and $f : Y \rightarrow X$ is a finite morphism of finite presentation (such sheaves are still constructible by Lemma 44.71.9 but we won't need this). Since formation of f_* commutes with any base change (Lemma 44.55.3) we see that the restriction of $f_*\underline{M}$ to X_0 is equal to the pushforward of \underline{M} via the induced morphism $Y_0 \rightarrow X_0$ of special fibres. By the Leray spectral sequence (Proposition 44.54.2) and vanishing of higher direct images (Proposition 44.55.2), we find

$$H^1_{\text{étale}}(X_0, f_*\underline{M}|_{X_0}) = H^1_{\text{étale}}(Y_0, \underline{M}).$$

Since $Y \rightarrow \text{Spec}(A)$ is proper we can use Lemma 44.76.3 to see that the $H^1_{\text{étale}}(Y_0, \underline{M})$ is equal to $H^1_{\text{étale}}(Y, \underline{M})$. Thus we see that our cohomology class ζ lifts to a cohomology class

$$\tilde{\zeta} \in H^1_{\text{étale}}(Y, \underline{M}) = H^1_{\text{étale}}(X, f_*\underline{M})$$

However, $\tilde{\zeta}$ maps to zero in $H^1_{\text{étale}}(X, \mathcal{I})$ as \mathcal{I} is injective and by commutativity of

$$\begin{array}{ccc} H^1_{\text{étale}}(X, f_*\underline{M}) & \longrightarrow & H^1_{\text{étale}}(X, \mathcal{I}) \\ \downarrow & & \downarrow \\ H^1_{\text{étale}}(X_0, (f_*\underline{M})|_{X_0}) & \longrightarrow & H^1_{\text{étale}}(X_0, \mathcal{I}|_{X_0}) \end{array}$$

we conclude that the image ξ of ζ is zero as well. □

44.77. The proper base change theorem

The proper base change theorem is stated and proved in this section. Our approach follows roughly the proof in [AGV71, XII, Theorem 5.1] using Gabber's ideas (from the affine case) to slightly simplify the arguments.

Lemma 44.77.1. *Let (A, I) be a henselian pair. Let $f : X \rightarrow \text{Spec}(A)$ be a proper morphism of schemes. Let $Z = X \times_{\text{Spec}(A)} \text{Spec}(A/I)$. For any sheaf \mathcal{F} on the topological space associated to X we have $\Gamma(X, \mathcal{F}) = \Gamma(Z, \mathcal{F}|_Z)$.*

Proof. We will use Lemma 44.74.8 to prove this. To do this let $Y \subset X$ be an irreducible closed subscheme. We have to show that $Y \cap Z = Y \times_{\text{Spec}(A)} \text{Spec}(A/I)$ is connected. Thus we may assume that X is irreducible and we have to show that Z is connected. Let $X \rightarrow \text{Spec}(B) \rightarrow \text{Spec}(A)$ be the Stein factorization of f (More on Morphisms, Theorem 36.36.4). Then $A \rightarrow B$ is integral and (B, IB) is a henselian pair (More on Algebra, Lemma 15.7.9). Thus we may assume the fibres of $X \rightarrow \text{Spec}(A)$ are geometrically connected. On the other hand, the image $T \subset \text{Spec}(A)$ of f is irreducible and closed as X is proper over A . Hence $T \cap V(I)$ is connected by More on Algebra, Lemma 15.7.11. Now $Y \times_{\text{Spec}(A)} \text{Spec}(A/I) \rightarrow T \cap V(I)$ is a surjective closed map with connected fibres. The result now follows from Topology, Lemma 5.6.4. □

Lemma 44.77.2. *Let (A, I) be a henselian pair. Let $f : X \rightarrow \text{Spec}(A)$ be a proper morphism of schemes. Let $i : Z \rightarrow X$ be the closed immersion of $X \times_{\text{Spec}(A)} \text{Spec}(A/I)$ into X . For any sheaf \mathcal{F} on $X_{\text{étale}}$ we have $\Gamma(X, \mathcal{F}) = \Gamma(Z, i_{\text{small}}^{-1}\mathcal{F})$.*

Proof. This follows from Lemma 44.74.7 and 44.77.1 and the fact that any scheme finite over X is proper over $\text{Spec}(A)$. □

Lemma 44.77.3. *Let A be a henselian local ring. Let $f : X \rightarrow \text{Spec}(A)$ be a proper morphism of schemes. Let $X_0 \subset X$ be the fibre of f over the closed point. For any sheaf \mathcal{F} on $X_{\text{étale}}$ we have $\Gamma(X, \mathcal{F}) = \Gamma(X_0, \mathcal{F}|_{X_0})$.*

Proof. This is a special case of Lemma 44.77.2. □

Let $f : X \rightarrow S$ be a morphism of schemes. Let $\bar{s} : \text{Spec}(k) \rightarrow S$ be a geometric point. The fibre of f at \bar{s} is the scheme $X_{\bar{s}} = \text{Spec}(k) \times_{\bar{s}, S} X$ viewed as a scheme over $\text{Spec}(k)$. If \mathcal{F} is a sheaf on $X_{\text{étale}}$, then denote $\mathcal{F}_{\bar{s}} = p_{\text{small}}^{-1}\mathcal{F}$ the pullback of \mathcal{F} to $(X_{\bar{s}})_{\text{étale}}$. In the following we will consider the set

$$\Gamma(X_{\bar{s}}, \mathcal{F}_{\bar{s}})$$

Let $s \in S$ be the image point of \bar{s} . Let $\kappa(s)^{\text{sep}}$ be the separable algebraic closure of $\kappa(s)$ in k as in Definition 44.57.1. By Lemma 44.40.4, pullback defines a bijection

$$\Gamma(X_{\kappa(s)^{\text{sep}}}, p_{\text{sep}}^{-1}\mathcal{F}) \longrightarrow \Gamma(X_{\bar{s}}, \mathcal{F}_{\bar{s}})$$

where $p_{\text{sep}} : X_{\kappa(s)^{\text{sep}}} = \text{Spec}(\kappa(s)^{\text{sep}}) \times_S X \rightarrow X$ is the projection.

Lemma 44.77.4. *Let $f : X \rightarrow S$ be a proper morphism of schemes. Let $\bar{s} \rightarrow S$ be a geometric point. For any sheaf \mathcal{F} on $X_{\text{étale}}$ the canonical map*

$$(f_*\mathcal{F})_{\bar{s}} \longrightarrow \Gamma(X_{\bar{s}}, \mathcal{F}_{\bar{s}})$$

is bijective.

Proof. By Theorem 44.53.1 (for sheaves of sets) we have

$$(f_*\mathcal{F})_{\bar{s}} = \Gamma(X \times_S \text{Spec}(\mathcal{O}_{S, \bar{s}}^{\text{sh}}), p_{\text{small}}^{-1}\mathcal{F})$$

where $p : X \times_S \text{Spec}(\mathcal{O}_{S, \bar{s}}^{\text{sh}}) \rightarrow X$ is the projection. Since the residue field of the strictly henselian local ring $\mathcal{O}_{S, \bar{s}}^{\text{sh}}$ is $\kappa(s)^{\text{sep}}$ we conclude from the discussion above the lemma and Lemma 44.77.3. □

Lemma 44.77.5. *Let $f : X \rightarrow Y$ be a proper morphism of schemes. Let $g : Y' \subset Y$ be a morphism of schemes. Set $X' = Y' \times_Y X$ with projections $f' : X' \rightarrow Y'$ and $g' : X' \rightarrow X$. Let \mathcal{F} be any sheaf on $X_{\text{étale}}$. Then $g^{-1}f_*\mathcal{F} = f'_*(g')^{-1}\mathcal{F}$.*

Proof. There is a canonical map $g^{-1}f_*\mathcal{F} \rightarrow f'_*(g')^{-1}\mathcal{F}$. Namely, it is adjoint to the map

$$f_*\mathcal{F} \longrightarrow g_*f'_*(g')^{-1}\mathcal{F} = f_*g'_*(g')^{-1}\mathcal{F}$$

which is f_* applied to the canonical map $\mathcal{F} \rightarrow g'_*(g')^{-1}\mathcal{F}$. To check this map is an isomorphism we can compute what happens on stalks. Let $y' : \text{Spec}(k) \rightarrow Y'$ be a geometric point with image y in Y . By Lemma 44.77.4 the stalks are $\Gamma(X'_{y'}, \mathcal{F}_{y'})$ and $\Gamma(X_y, \mathcal{F}_y)$ respectively. Here the sheaves \mathcal{F}_y and $\mathcal{F}_{y'}$ are the pullbacks of \mathcal{F} by the projections $X_y \rightarrow X$ and $X'_{y'} \rightarrow X$. Thus we see that the groups agree by Lemma 44.40.4. We omit the verification that this isomorphism is compatible with our map. □

At this point we start discussing the proper base change theorem. To do so we introduce some notation. consider a commutative diagram

$$(44.77.5.1) \quad \begin{array}{ccc} X' & \longrightarrow & X \\ f' \downarrow & & \downarrow f \\ Y' & \xrightarrow{g} & Y \end{array}$$

of morphisms of schemes. Then we obtain a commutative diagram of sites

$$\begin{array}{ccc} X'_{\acute{e}tale} & \xrightarrow{g'_{small}} & X_{\acute{e}tale} \\ f'_{small} \downarrow & & \downarrow f_{small} \\ Y'_{\acute{e}tale} & \xrightarrow{g_{small}} & Y_{\acute{e}tale} \end{array}$$

For any object E of $D(X_{\acute{e}tale})$ we obtain a canonical base change map

$$(44.77.5.2) \quad g_{small}^{-1} Rf_{small,*} E \longrightarrow Rf'_{small,*} (g'_{small})^{-1} E$$

in $D(Y'_{\acute{e}tale})$. See Cohomology on Sites, Remark 21.19.2 where we use the constant sheaf \mathbf{Z} as our sheaf of rings. We will usually omit the subscripts $_{small}$ in this formula. For example, if $E = \mathcal{F}[0]$ where \mathcal{F} is an abelian sheaf on $X_{\acute{e}tale}$, the base change map is a map

$$(44.77.5.3) \quad g^{-1} Rf_* \mathcal{F} \longrightarrow Rf'_*(g')^{-1} \mathcal{F}$$

in $D(Y'_{\acute{e}tale})$.

The map (44.77.5.2) has no chance of being an isomorphism in the generality given above. The goal is to show it is an isomorphism if the diagram (44.77.5.1) is cartesian, $f : X \rightarrow Y$ proper, and the cohomology sheaves of E are torsion. To study this question we introduce the following terminology. Let us say that *cohomology commutes with base change for $f : X \rightarrow Y$* if (44.77.5.3) is an isomorphism for every diagram (44.77.5.1) where $X' = Y' \times_Y X$ and every torsion abelian sheaf \mathcal{F} .

Lemma 44.77.6. *Let $f : X \rightarrow Y$ be a proper morphism of schemes. The following are equivalent*

- (1) *cohomology commutes with base change for f (see above),*
- (2) *for every prime number ℓ and every injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules \mathcal{I} on $X_{\acute{e}tale}$ and every diagram (44.77.5.1) where $X' = Y' \times_Y X$ the sheaves $R^q f'_*(g')^{-1} \mathcal{I}$ are zero for $q > 0$.*

Proof. It is clear that (1) implies (2). Conversely, assume (2) and let \mathcal{F} be an abelian sheaf on $X_{\acute{e}tale}$. Let $Y' \rightarrow Y$ be a morphism of schemes and let $X' = Y' \times_Y X$ with projections $g' : X' \rightarrow X$ and $f' : X' \rightarrow Y'$ as in diagram (44.77.5.1). We want to show the maps of sheaves

$$g^{-1} R^q f_* \mathcal{F} \longrightarrow R^q f'_*(g')^{-1} \mathcal{F}$$

are isomorphisms for all $q \geq 0$.

For every $n \geq 1$, let $\mathcal{F}[n]$ be the subsheaf of sections of \mathcal{F} annihilated by n . Then $\mathcal{F} = \text{colim } \mathcal{F}[n]$. The functors g^{-1} and $(g')^{-1}$ commute with arbitrary colimits (as left adjoints). Taking higher direct images along f or f' commutes with filtered colimits by Lemma 44.52.5. Hence we see that

$$g^{-1} R^q f_* \mathcal{F} = \text{colim } g^{-1} R^q f_* \mathcal{F}[n] \quad \text{and} \quad R^q f'_*(g')^{-1} \mathcal{F} = \text{colim } R^q f'_*(g')^{-1} \mathcal{F}[n]$$

Thus it suffices to prove the result in case \mathcal{F} is annihilated by a positive integer n . If $n = \ell n'$ for some prime number ℓ , then we obtain a short exact sequence

$$0 \rightarrow \mathcal{F}[\ell] \rightarrow \mathcal{F} \rightarrow \mathcal{F}/\mathcal{F}[\ell] \rightarrow 0$$

Observe that $\mathcal{F}/\mathcal{F}[\ell]$ is annihilated by n' . Moreover, if the result holds for both $\mathcal{F}[\ell]$ and $\mathcal{F}/\mathcal{F}[\ell]$, then the result holds by the long exact sequence of higher direct images (and the 5 lemma). In this way we reduce to the case that \mathcal{F} is annihilated by a prime number ℓ .

Assume \mathcal{F} is annihilated by a prime number ℓ . Choose an injective resolution $\mathcal{F} \rightarrow \mathcal{I}^\bullet$ in $D(X_{\acute{e}tale}, \mathbf{Z}/\ell\mathbf{Z})$. Applying assumption (2) and Leray’s acyclicity lemma (Derived Categories, Lemma 13.17.7) we see that

$$f'_*(g')^{-1}\mathcal{I}^\bullet$$

computes $Rf'_*(g')^{-1}\mathcal{F}$. We conclude by applying Lemma 44.77.5. □

Lemma 44.77.7. *Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be proper morphisms of schemes. Assume*

- (1) *cohomology commutes with base change for f ,*
- (2) *cohomology commutes with base change for $g \circ f$, and*
- (3) *f is surjective.*

Then cohomology commutes with base change for g .

Proof. We will use the equivalence of Lemma 44.77.6 without further mention. Let ℓ be a prime number. Let \mathcal{I} be an injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $Y_{\acute{e}tale}$. Choose an injective map of sheaves $f^{-1}\mathcal{I} \rightarrow \mathcal{J}$ where \mathcal{J} is an injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $Z_{\acute{e}tale}$. Since f is surjective the map $\mathcal{I} \rightarrow f_*\mathcal{J}$ is injective (look at stalks in geometric points). Since \mathcal{I} is injective we see that \mathcal{I} is a direct summand of $f_*\mathcal{J}$. Thus it suffices to prove the desired vanishing for $f_*\mathcal{J}$.

Let $Z' \rightarrow Z$ be a morphism of schemes and set $Y' = Z' \times_Z Y$ and $X' = Z' \times_Z X = Y' \times_Y X$. Denote $a : X' \rightarrow X$, $b : Y' \rightarrow Y$, and $c : Z' \rightarrow Z$ the projections. Similarly for $f' : X' \rightarrow Y'$ and $g' : Y' \rightarrow Z'$. By Lemma 44.77.5 we have $b^{-1}f_*\mathcal{J} = f'_*a^{-1}\mathcal{J}$. On the other hand, we know that $R^q f'_*a^{-1}\mathcal{J}$ and $R^q(g' \circ f')_*a^{-1}\mathcal{J}$ are zero for $q > 0$. Using the spectral sequence (Cohomology on Sites, Lemma 21.14.7)

$$R^p g'_* R^q f'_* a^{-1}\mathcal{J} \Rightarrow R^{p+q}(g' \circ f')_* a^{-1}\mathcal{J}$$

we conclude that $R^p g'_*(b^{-1}f_*\mathcal{J}) = R^p g'_*(f'_*a^{-1}\mathcal{J}) = 0$ for $p > 0$ as desired. □

Lemma 44.77.8. *Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be proper morphisms of schemes. Assume*

- (1) *cohomology commutes with base change for f , and*
- (2) *cohomology commutes with base change for g .*

Then cohomology commutes with base change for $f \circ g$.

Proof. We will use the equivalence of Lemma 44.77.6 without further mention. Let ℓ be a prime number. Let \mathcal{I} be an injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $X_{\acute{e}tale}$. Then $f_*\mathcal{I}$ is an injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $Y_{\acute{e}tale}$ (Cohomology on Sites, Lemma 21.14.2). The result follows formally from this, but we will also spell it out.

Let $Z' \rightarrow Z$ be a morphism of schemes and set $Y' = Z' \times_Z Y$ and $X' = Z' \times_Z X = Y' \times_Y X$. Denote $a : X' \rightarrow X$, $b : Y' \rightarrow Y$, and $c : Z' \rightarrow Z$ the projections. Similarly

for $f' : X' \rightarrow Y'$ and $g' : Y' \rightarrow Z'$. By Lemma 44.77.5 we have $b^{-1}f_*\mathcal{I} = f'_*a^{-1}\mathcal{I}$. On the other hand, we know that $R^q f'_*a^{-1}\mathcal{I}$ and $R^q(g')_*b^{-1}f_*\mathcal{I}$ are zero for $q > 0$. Using the spectral sequence (Cohomology on Sites, Lemma 21.14.7)

$$R^p g'_* R^q f'_* a^{-1} \mathcal{I} \Rightarrow R^{p+q} (g' \circ f')_* a^{-1} \mathcal{I}$$

we conclude that $R^p(g' \circ f')_* a^{-1} \mathcal{I} = 0$ for $p > 0$ as desired. □

Lemma 44.77.9. *Let $f : X \rightarrow Y$ be a finite morphism of schemes. Then cohomology commutes with base change for f .*

Proof. Observe that a finite morphism is proper, see Morphisms, Lemma 28.44.10. Moreover, the base change of a finite morphism is finite, see Morphisms, Lemma 28.44.6. Thus the result follows from Lemma 44.77.6 combined with Proposition 44.55.2. □

Lemma 44.77.10. *To prove that cohomology commutes with base change for every proper morphism of schemes it suffices to prove it holds for the morphism $\mathbf{P}_S^1 \rightarrow S$ for every scheme S .*

Proof. Let $f : X \rightarrow Y$ be a proper morphism of schemes. Let $Y = \bigcup Y_i$ be an affine open covering and set $X_i = f^{-1}(Y_i)$. If we can prove cohomology commutes with base change for $X_i \rightarrow Y_i$, then cohomology commutes with base change for f . Namely, the formation of the higher direct images commutes with Zariski (and even étale) localization on the base, see Lemma 44.52.4. Thus we may assume Y is affine.

Let Y be an affine scheme and let $X \rightarrow Y$ be a proper morphism. By Chow's lemma there exists a commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{\pi} & X' & \longrightarrow & \mathbf{P}_Y^n \\ & \searrow & \downarrow & \swarrow & \\ & & Y & & \end{array}$$

where $X' \rightarrow \mathbf{P}_Y^n$ is an immersion, and $\pi : X' \rightarrow X$ is proper and surjective, see Limits, Lemma 31.11.1. Since $X \rightarrow Y$ is proper, we find that $X' \rightarrow Y$ is proper (Morphisms, Lemma 28.42.4). Hence $X' \rightarrow \mathbf{P}_Y^n$ is a closed immersion (Morphisms, Lemma 28.42.7). It follows that $X' \rightarrow X \times_Y \mathbf{P}_Y^n = \mathbf{P}_X^n$ is a closed immersion (as an immersion with closed image).

By Lemma 44.77.7 it suffices to prove cohomology commutes with base change for π and $X' \rightarrow Y$. These morphisms both factor as a closed immersion followed by a projection $\mathbf{P}_S^n \rightarrow S$ (for some S). By Lemma 44.77.9 the result holds for closed immersions (as closed immersions are finite). By Lemma 44.77.8 it suffices to prove the result for projections $\mathbf{P}_S^n \rightarrow S$.

For every $n \geq 1$ there is a finite surjective morphism

$$\mathbf{P}_S^1 \times_S \dots \times_S \mathbf{P}_S^1 \longrightarrow \mathbf{P}_S^n$$

given on coordinates by

$$((x_1 : y_1), (x_2 : y_2), \dots, (x_n : y_n)) \longmapsto (F_0 : \dots : F_n)$$

where F_0, \dots, F_n in x_1, \dots, y_n are the polynomials with integer coefficients such that

$$\prod (x_i t + y_i) = F_0 t^n + F_1 t^{n-1} + \dots + F_n$$

Applying Lemmas 44.77.7, 44.77.9, and 44.77.8 one more time we conclude that the lemma is true. \square

Theorem 44.77.11. *Let $f : X \rightarrow Y$ be a proper morphism of schemes. Let $g : Y' \rightarrow Y$ be a morphism of schemes. Set $X' = Y' \times_Y X$ and consider the cartesian diagram*

$$\begin{array}{ccc} X' & \xrightarrow{\quad} & X \\ f' \downarrow & & \downarrow f \\ Y' & \xrightarrow{\quad g \quad} & Y \end{array}$$

Let \mathcal{F} be an abelian torsion sheaf on $X_{\acute{e}tale}$. Then the base change map

$$g^{-1} Rf_* \mathcal{F} \longrightarrow Rf'_*(g')^{-1} \mathcal{F}$$

is an isomorphism.

Proof. In the terminology introduced above, this means that cohomology commutes with base change for every proper morphism of schemes. By Lemma 44.77.10 it suffices to prove that cohomology commutes with base change for the morphism $\mathbf{P}_S^1 \rightarrow S$ for every scheme S .

Let S be the spectrum of a strictly henselian local ring with closed point s . Set $X = \mathbf{P}_S^1$ and $X_0 = X_s = \mathbf{P}_s^1$. Let \mathcal{F} be a sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $X_{\acute{e}tale}$. The key to our proof is that

$$H_{\acute{e}tale}^q(X, \mathcal{F}) = H_{\acute{e}tale}^q(X_0, \mathcal{F}|_{X_0}).$$

Namely, choose a resolution $\mathcal{F} \rightarrow \mathcal{I}^\bullet$ by injective sheaves of $\mathbf{Z}/\ell\mathbf{Z}$ -modules. Then $\mathcal{I}^\bullet|_{X_0}$ is a resolution of $\mathcal{F}|_{X_0}$ by right $H_{\acute{e}tale}^0(X_0, -)$ -acyclic objects, see Lemma 44.76.4. Leray’s acyclicity lemma tells us the right hand side is computed by the complex $H_{\acute{e}tale}^0(X_0, \mathcal{I}^\bullet|_{X_0})$ which is equal to $H_{\acute{e}tale}^0(X, \mathcal{I}^\bullet)$ by Lemma 44.77.3. This complex computes the left hand side.

Assume S is general and \mathcal{F} is a sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules on $X_{\acute{e}tale}$. Let $\bar{s} : \text{Spec}(k) \rightarrow S$ be a geometric point of S lying over $s \in S$. We have

$$(R^q f_* \mathcal{F})_{\bar{s}} = H_{\acute{e}tale}^q(\mathbf{P}_{\mathcal{O}_{S, \bar{s}}}^1, \mathcal{F}|_{\mathbf{P}_{\mathcal{O}_{S, \bar{s}}}^1}) = H_{\acute{e}tale}^q(\mathbf{P}_{\kappa(s)^{sep}}^1, \mathcal{F}|_{\mathbf{P}_{\kappa(s)^{sep}}^1})$$

where $\kappa(s)^{sep}$ is the residue field of $\mathcal{O}_{S, \bar{s}}^{sh}$, i.e., the separable algebraic closure of $\kappa(s)$ in k . The first equality by Theorem 44.53.1 and the second equality by the displayed formula in the previous paragraph.

Finally, consider any morphism of schemes $g : T \rightarrow S$ where S and \mathcal{F} are as above. Set $f' : \mathbf{P}_T^1 \rightarrow T$ the projection and let $g' : \mathbf{P}_T^1 \rightarrow \mathbf{P}_T^1$ the morphism induced by g . Consider the base change map

$$g^{-1} R^q f_* \mathcal{F} \longrightarrow R^q f'_*(g')^{-1} \mathcal{F}$$

Let \bar{t} be a geometric point of T with image $\bar{s} = g(\bar{t})$. By our discussion above the map on stalks at \bar{t} is the map

$$H_{\acute{e}tale}^q(\mathbf{P}_{\kappa(s)^{sep}}^1, \mathcal{F}|_{\mathbf{P}_{\kappa(s)^{sep}}^1}) \longrightarrow H_{\acute{e}tale}^q(\mathbf{P}_{\kappa(t)^{sep}}^1, \mathcal{F}|_{\mathbf{P}_{\kappa(t)^{sep}}^1})$$

Since $\kappa(s)^{sep} \subset \kappa(t)^{sep}$ this map is an isomorphism by Lemma 44.75.15.

This proves cohomology commutes with base change for $\mathbf{P}_S^1 \rightarrow S$ and sheaves of $\mathbf{Z}/\ell\mathbf{Z}$ -modules. In particular, for an injective sheaf of $\mathbf{Z}/\ell\mathbf{Z}$ -modules the higher direct images of any base change are zero. In other words, condition (2) of Lemma 44.77.6 holds and the proof is complete. \square

44.78. Applications of proper base change

As an application of the proper base change theorem we obtain the following.

Lemma 44.78.1. *Let $f : X \rightarrow Y$ be a proper morphism of schemes all of whose fibres have dimension $\leq n$. Then for any abelian torsion sheaf \mathcal{F} on $X_{\acute{e}tale}$ we have $R^q f_* \mathcal{F} = 0$ for $q > 2n$.*

Proof. Omitted. Hints: By the proper base change theorem it suffices to prove that for a proper scheme X over an algebraically closed field, the étale cohomology of \mathcal{F} vanishes above $2 \dim X$. By the proper base change theorem and dévissage (using Chow’s lemma for example) one can reduce to the case where the dimension of X is 1. The case of curves is Theorem 44.75.14. See also Remarks 44.75.13. \square

Lemma 44.78.2. *Let $f : X \rightarrow Y$ be a morphism of finite type with Y quasi-compact. Then the dimension of the fibres of f is bounded.*

Proof. By Morphisms, Lemma 28.29.4 the set $U_n \subset X$ of points where the dimension of the fibre is $\leq n$ is open. Since f is of finite type, every point is contained in some U_n . Since Y is quasi-compact and f is of finite type, we see that X is quasi-compact. Hence $X = U_n$ for some n . \square

44.79. The trace formula

A typical course in étale cohomology would normally state and prove the proper and smooth base change theorems, purity and Poincaré duality. All of these can be found in [Del77, Arcata]. Instead, we are going to study the trace formula for the Frobenius, following the account of Deligne in [Del77, Rapport]. We will only look at dimension 1, but using proper base change this is enough for the general case. Since all the cohomology groups considered will be étale, we drop the subscript *étale*. Let us now describe the formula we are after. Let X be a finite type scheme of dimension 1 over a finite field k , ℓ a prime number and \mathcal{F} a constructible, flat $\mathbf{Z}/\ell^n\mathbf{Z}$ sheaf. Then

$$(44.79.0.1) \quad \sum_{x \in X(k)} \mathrm{Tr}(\mathrm{Frob} | \mathcal{F}_{\bar{x}}) = \sum_{i=0}^2 (-1)^i \mathrm{Tr}(\pi_X^* | H_c^i(X \otimes_k \bar{k}, \mathcal{F}))$$

as elements of $\mathbf{Z}/\ell^n\mathbf{Z}$. As we will see, this formulation is slightly wrong as stated. Let us nevertheless describe the symbols that occur therein.

44.80. Frobenii

In this section we will prove a “baffling” theorem. A topological analogue of the baffling theorem is the following.

Exercise 44.80.1. Let X be a topological space and $g : X \rightarrow X$ a continuous map such that $g^{-1}(U) = U$ for all opens U of X . Then g induces the identity on cohomology on X (for any coefficients).

We now turn to the statement for the étale site.

Lemma 44.80.2. *Let X be a scheme and $g : X \rightarrow X$ a morphism. Assume that for all $\varphi : U \rightarrow X$ étale, there is an isomorphism*

$$\begin{array}{ccc} U & \xrightarrow{\sim} & U \times_{\varphi, X, g} X \\ & \searrow \varphi & \swarrow \text{pr}_2 \\ & & X \end{array}$$

functorial in U . Then g induces the identity on cohomology (for any sheaf).

Proof. The proof is formal and without difficulty. □

Definition 44.80.3. Let X be a scheme in characteristic p . The *absolute frobenius* of X is the morphism $F_X : X \rightarrow X$ which is the identity on the induced topological space, and which takes a function to its p th power. Thus $F_X^\sharp : \mathcal{O}_X \rightarrow \mathcal{O}_X$ is given by $g \mapsto g^p$.

Theorem 44.80.4 (The Baffling Theorem). *Let X be a scheme in characteristic $p > 0$. Then the absolute frobenius induces (by pullback) the trivial map on cohomology, i.e., for all integers $j \geq 0$,*

$$F_X^* : H^j(X, \underline{\mathbf{Z}/n\mathbf{Z}}) \rightarrow H^j(X, \underline{\mathbf{Z}/n\mathbf{Z}})$$

is the identity.

This theorem is purely formal. It is a good idea, however, to review how to compute the pullback of a cohomology class. Let us simply say that in the case where cohomology agrees with Čech cohomology, it suffices to pull back (using the fiber products on a site) the Čech cocycles. The general case is quite technical, see Hypercoverings, Theorem 24.9.1. To prove the theorem, we merely verify that the assumption of Lemma 44.80.2 holds for the frobenius.

Proof of Theorem 44.80.4. We need to verify the existence of a functorial isomorphism as above. For an étale morphism $\varphi : U \rightarrow X$, consider the diagram

$$\begin{array}{ccc} U & \xrightarrow{F_U} & U \\ \text{dotted} \searrow & & \downarrow \varphi \\ U \times_{\varphi, X, F_X} X^{\text{pr}_1} & \xrightarrow{\text{pr}_1} & U \\ \downarrow \varphi & & \downarrow \varphi \\ X & \xrightarrow{F_X} & X \end{array}$$

The dotted arrow is an étale morphism which induces an isomorphism on the underlying topological spaces, so it is an isomorphism. □

Definition 44.80.5. Let k be a finite field with $q = p^f$ elements. Let X be a scheme over k . The *geometric frobenius* of X is the morphism $\pi_X : X \rightarrow X$ over $\text{Spec}(k)$ which equals F_X^f .

Since π_X is a morphism over k , we can base change it to any scheme over k . In particular we can base change it to the algebraic closure \bar{k} and get a morphism $\pi_X : X_{\bar{k}} \rightarrow X_{\bar{k}}$. Using π_X also for this base change should not be confusing as $X_{\bar{k}}$ does not have a geometric frobenius of its own.

Lemma 44.80.6. *Let \mathcal{F} be a sheaf on $X_{\acute{e}tale}$. Then there are canonical isomorphisms $\pi_X^{-1}\mathcal{F} \cong \mathcal{F}$ and $\mathcal{F} \cong \pi_{X*}\mathcal{F}$.*

This is false for the fppf site.

Proof. Let $\varphi : U \rightarrow X$ be étale. Recall that $\pi_{X*}\mathcal{F}(U) = \mathcal{F}(U \times_{\varphi, X, \pi_X} X)$. Since $\pi_X = F_X^f$, it follows from the proof of Theorem 44.80.4 that there is a functorial isomorphism

$$\begin{array}{ccc} U & \xrightarrow{\gamma_U} & U \times_{\varphi, X, \pi_X} X \\ & \searrow \varphi & \swarrow \text{pr}_2 \\ & & X \end{array}$$

where $\gamma_U = (\varphi, F_U^f)$. Now we define an isomorphism

$$\mathcal{F}(U) \longrightarrow \pi_{X*}\mathcal{F}(U) = \mathcal{F}(U \times_{\varphi, X, \pi_X} X)$$

by taking the restriction map of \mathcal{F} along γ_U^{-1} . The other isomorphism is analogous. \square

Remark 44.80.7. It may or may not be the case that F_U^f equals π_U .

We continue discussion cohomology of sheaves on our scheme X over the finite field k with $q = p^f$ elements. Fix an algebraic closure \bar{k} of k and write $G_k = \text{Gal}(\bar{k}/k)$ for the absolute Galois group of k . Let \mathcal{F} be an abelian sheaf on $X_{\acute{e}tale}$. We will define a left G_k -module structure cohomology group $H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}})$ as follows: if $\sigma \in G_k$, the diagram

$$\begin{array}{ccc} X_{\bar{k}} & \xrightarrow{\text{Spec}(\sigma) \times \text{id}_X} & X_{\bar{k}} \\ & \searrow & \swarrow \\ & & X \end{array}$$

commutes. Thus we can set, for $\xi \in H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}})$

$$\sigma \cdot \xi := (\text{Spec}(\sigma) \times \text{id}_X)^*\xi \in H^j(X_{\bar{k}}, (\text{Spec}(\sigma) \times \text{id}_X)^{-1}\mathcal{F}|_{X_{\bar{k}}}) = H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}}),$$

where the last equality follows from the commutativity of the previous diagram. This endows the latter group with the structure of a G_k -module.

Lemma 44.80.8. *In the situation above denote $\alpha : X \rightarrow \text{Spec}(k)$ the structure morphism. Consider the stalk $(R^j\alpha_*\mathcal{F})_{\text{Spec}(\bar{k})}$ endowed with its natural Galois action as in Section 44.57. Then the identification*

$$(R^j\alpha_*\mathcal{F})_{\text{Spec}(\bar{k})} \cong H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}})$$

from Theorem 44.53.1 is an isomorphism of G_k -modules.

A similar result holds comparing $(R^j\alpha_*\mathcal{F})_{\text{Spec}(\bar{k})}$ with $H_c^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}})$.

Proof. Omitted. \square

Definition 44.80.9. The *arithmetic frobenius* is the map $\text{frob}_k : \bar{k} \rightarrow \bar{k}$, $x \mapsto x^q$ of G_k .

Theorem 44.80.10. *Let \mathcal{F} be an abelian sheaf on $X_{\acute{e}tale}$. Then for all $j \geq 0$, frob_k acts on the cohomology group $H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}})$ as the inverse of the map π_X^* .*

The map π_X^* is defined by the composition

$$H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}}) \xrightarrow{\pi_{X_{\bar{k}}}^*} H^j(X_{\bar{k}}, (\pi_X^{-1}\mathcal{F})|_{X_{\bar{k}}}) \cong H^j(X_{\bar{k}}, \mathcal{F}|_{X_{\bar{k}}}).$$

where the last isomorphism comes from the canonical isomorphism $\pi_X^{-1}\mathcal{F} \cong \mathcal{F}$ of Lemma 44.80.6.

Proof. The composition $X_{\bar{k}} \xrightarrow{\text{Spec}(\text{frob}_k)} X_{\bar{k}} \xrightarrow{\pi_X} X_{\bar{k}}$ is equal to $F_{X_{\bar{k}}}^f$, hence the result follows from the baffling theorem suitably generalized to nontrivial coefficients. Note that the previous composition commutes in the sense that $F_{X_{\bar{k}}}^f = \pi_X \circ \text{Spec}(\text{frob}_k) = \text{Spec}(\text{frob}_k) \circ \pi_X$. \square

Definition 44.80.11. If $x \in X(k)$ is a rational point and $\bar{x} : \text{Spec}(\bar{k}) \rightarrow X$ the geometric point lying over x , we let $\pi_x : \mathcal{F}_{\bar{x}} \rightarrow \mathcal{F}_{\bar{x}}$ denote the action by frob_k^{-1} and call it the *geometric frobenius*⁶

We can now make a more precise statement (albeit a false one) of the trace formula (44.79.0.1). Let X be a finite type scheme of dimension 1 over a finite field k , ℓ a prime number and \mathcal{F} a constructible, flat $\mathbf{Z}/\ell^n\mathbf{Z}$ sheaf. Then

$$(44.80.11.1) \quad \sum_{x \in X(k)} \text{Tr}(\pi_X|_{\mathcal{F}_{\bar{x}}}) = \sum_{i=0}^2 (-1)^i \text{Tr}(\pi_X^*|_{H_c^i(X_{\bar{k}}, \mathcal{F})})$$

as elements of $\mathbf{Z}/\ell^n\mathbf{Z}$. The reason this equation is wrong is that the trace in the right-hand side does not make sense for the kind of sheaves considered. Before addressing this issue, we try to motivate the appearance of the geometric frobenius (apart from the fact that it is a natural morphism!).

Let us consider the case where $X = \mathbf{P}_k^1$ and $\mathcal{F} = \underline{\mathbf{Z}/\ell\mathbf{Z}}$. For any point, the Galois module $\mathcal{F}_{\bar{x}}$ is trivial, hence for any morphism φ acting on $\mathcal{F}_{\bar{x}}$, the left-hand side is

$$\sum_{x \in X(k)} \text{Tr}(\varphi|_{\mathcal{F}_{\bar{x}}}) = \#\mathbf{P}_k^1(k) = q + 1.$$

Now \mathbf{P}_k^1 is proper, so compactly supported cohomology equals standard cohomology, and so for a morphism $\pi : \mathbf{P}_k^1 \rightarrow \mathbf{P}_k^1$, the right-hand side equals

$$\text{Tr}(\pi^*|_{H^0(\mathbf{P}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})}) + \text{Tr}(\pi^*|_{H^2(\mathbf{P}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})}).$$

The Galois module $H^0(\mathbf{P}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}}) = \underline{\mathbf{Z}/\ell\mathbf{Z}}$ is trivial, since the pullback of the identity is the identity. Hence the first trace is 1, regardless of π . For the second trace, we need to compute the pullback $\pi^* : H^2(\mathbf{P}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})$ for a map $\pi : \mathbf{P}_k^1 \rightarrow \mathbf{P}_k^1$. This is a good exercise and the answer is multiplication by the degree of π (for a proof see Lemma 44.66.4). In other words, this works as in the familiar situation of complex cohomology. In particular, if π is the geometric frobenius we get

$$\text{Tr}(\pi_X^*|_{H^2(\mathbf{P}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})}) = q$$

and if π is the arithmetic frobenius then we get

$$\text{Tr}(\text{frob}_k^*|_{H^2(\mathbf{P}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})}) = q^{-1}.$$

The latter option is clearly wrong.

⁶This notation is not standard. This operator is denoted F_x in [Del77]. We will likely change this notation in the future.

Remark 44.80.12. The computation of the degrees can be done by lifting (in some obvious sense) to characteristic 0 and considering the situation with complex coefficients. This method almost never works, since lifting is in general impossible for schemes which are not projective space.

The question remains as to why we have to consider compactly supported cohomology. In fact, in view of Poincaré duality, it is not strictly necessary for smooth varieties, but it involves adding in certain powers of q . For example, let us consider the case where $X = \mathbf{A}_k^1$ and $\mathcal{F} = \underline{\mathbf{Z}/\ell\mathbf{Z}}$. The action on stalks is again trivial, so we only need look at the action on cohomology. But then π_X^* acts as the identity on $H^0(\mathbf{A}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})$ and as multiplication by q on $H_c^2(\mathbf{A}_k^1, \underline{\mathbf{Z}/\ell\mathbf{Z}})$.

44.81. Traces

We now explain how to take the trace of an endomorphism of a module over a noncommutative ring. Fix a finite ring Λ with cardinality prime to p . Typically, Λ is the group ring $(\mathbf{Z}/\ell^n\mathbf{Z})[G]$ for some finite group G . By convention, all the Λ -modules considered will be left Λ -modules.

We introduce the following notation: We set Λ^{\natural} to be the quotient of Λ by its additive subgroup generated by the commutators (i.e., the elements of the form $ab - ba$, $a, b \in \Lambda$). Note that Λ^{\natural} is not a ring.

For instance, the module $(\mathbf{Z}/\ell^n\mathbf{Z})[G]^{\natural}$ is the dual of the class functions, so

$$(\mathbf{Z}/\ell^n\mathbf{Z})[G]^{\natural} = \bigoplus_{\text{conjugacy classes of } G} \mathbf{Z}/\ell^n\mathbf{Z}.$$

For a free Λ -module, we have $\text{End}_{\Lambda}(\Lambda^{\oplus m}) = \text{Mat}_m(\Lambda)$. Note that since the modules are left modules, representation of endomorphism by matrices is a right action: if $a \in \text{End}(\Lambda^{\oplus m})$ has matrix A and $v \in \Lambda$, then $a(v) = vA$.

Definition 44.81.1. The *trace* of the endomorphism a is the sum of the diagonal entries of a matrix representing it. This defines an additive map $\text{Tr} : \text{End}_{\Lambda}(\Lambda^{\oplus m}) \rightarrow \Lambda^{\natural}$.

Exercise 44.81.2. Given maps

$$\Lambda^{\oplus n} \xrightarrow{a} \Lambda^{\oplus n} \xrightarrow{b} \Lambda^{\oplus m}$$

show that $\text{Tr}(ab) = \text{Tr}(ba)$.

We extend the definition of the trace to a finite projective Λ -module P and an endomorphism φ of P as follows. Write P as the summand of a free Λ -module, i.e., consider maps $P \xrightarrow{a} \Lambda^{\oplus n} \xrightarrow{b} P$ with

- (1) $\Lambda^{\oplus n} = \text{Im}(a) \oplus \text{Ker}(b)$; and
- (2) $b \circ a = \text{id}_P$.

Then we set $\text{Tr}(\varphi) = \text{Tr}(a\varphi b)$. It is easy to check that this is well-defined, using the previous exercise.

44.82. Why derived categories?

With this definition of the trace, let us now discuss another issue with the formula as stated. Let C be a smooth projective curve over k . Then there is a correspondence between finite locally constant sheaves \mathcal{F} on $C_{\acute{e}tale}$ which stalks are isomorphic to $(\mathbf{Z}/\ell^n\mathbf{Z})^{\oplus m}$ on the one hand, and continuous representations $\rho : \pi_1(C, \bar{c}) \rightarrow$

$\mathrm{GL}_m(\mathbf{Z}/\ell^n\mathbf{Z})$ (for some fixed choice of \bar{c}) on the other hand. We denote \mathcal{F}_ρ the sheaf corresponding to ρ . Then $H^2(C_{\bar{k}}, \mathcal{F}_\rho)$ is the group of coinvariants for the action of $\rho(\pi_1(C, \bar{c}))$ on $(\mathbf{Z}/\ell^n\mathbf{Z})^{\oplus m}$, and there is a short exact sequence

$$0 \longrightarrow \pi_1(C_{\bar{k}}, \bar{c}) \longrightarrow \pi_1(C, \bar{c}) \longrightarrow G_k \longrightarrow 0.$$

For instance, let $\mathbf{Z} = \mathbf{Z}\sigma$ act on $\mathbf{Z}/\ell^2\mathbf{Z}$ via $\sigma(x) = (1 + \ell)x$. The coinvariants are $(\mathbf{Z}/\ell^2\mathbf{Z})_\sigma = \mathbf{Z}/\ell\mathbf{Z}$, which is not a flat $\mathbf{Z}/\ell\mathbf{Z}$ -module. Hence we cannot take the trace of some action on $H^2(C_{\bar{k}}, \mathcal{F}_\rho)$, at least not in the sense of the previous section.

In fact, our goal is to consider a trace formula for ℓ -adic coefficients. But $\mathbf{Q}_\ell = \mathbf{Z}_\ell[1/\ell]$ and $\mathbf{Z}_\ell = \lim \mathbf{Z}/\ell^n\mathbf{Z}$, and even for a flat $\mathbf{Z}/\ell^n\mathbf{Z}$ sheaf, the individual cohomology groups may not be flat, so we cannot compute traces. One possible remedy is consider the total derived complex $R\Gamma(C_{\bar{k}}, \mathcal{F}_\rho)$ in the derived category $D(\mathbf{Z}/\ell^n\mathbf{Z})$ and show that it is a perfect object, which means that it is quasi-isomorphic to a finite complex of finite free module. For such complexes, we can define the trace, but this will require an account of derived categories.

44.83. Derived categories

To set up notation, let \mathcal{A} be an abelian category. Let $\mathrm{Comp}(\mathcal{A})$ be the abelian category of complexes in \mathcal{A} . Let $K(\mathcal{A})$ be the category of complexes up to homotopy, with objects equal to complexes in \mathcal{A} and objects equal to homotopy classes of morphisms of complexes. This is not an abelian category. Loosely speaking, $D(\mathcal{A})$ is defined to be the category obtained by inverting all quasi-isomorphisms in $\mathrm{Comp}(\mathcal{A})$ or, equivalently, in $K(\mathcal{A})$. Moreover, we can define $\mathrm{Comp}^+(\mathcal{A}), K^+(\mathcal{A}), D^+(\mathcal{A})$ analogously using only bounded below complexes. Similarly, we can define $\mathrm{Comp}^-(\mathcal{A}), K^-(\mathcal{A}), D^-(\mathcal{A})$ using bounded above complexes, and we can define $\mathrm{Comp}^b(\mathcal{A}), K^b(\mathcal{A}), D^b(\mathcal{A})$ using bounded complexes.

Remark 44.83.1. Notes on derived categories.

- (1) There are some set-theoretical problems when \mathcal{A} is somewhat arbitrary, which we will happily disregard.
- (2) The categories $K(\mathcal{A})$ and $D(\mathcal{A})$ may be endowed with the structure of triangulated category, but we will not need these structures in the following discussion.
- (3) The categories $\mathrm{Comp}(\mathcal{A})$ and $K(\mathcal{A})$ can also be defined when \mathcal{A} is an additive category.

The homology functor $H^i : \mathrm{Comp}(\mathcal{A}) \rightarrow \mathcal{A}$ taking a complex $K^\bullet \mapsto H^i(K^\bullet)$ extends to functors $H^i : K(\mathcal{A}) \rightarrow \mathcal{A}$ and $H^i : D(\mathcal{A}) \rightarrow \mathcal{A}$.

Lemma 44.83.2. *An object E of $D(\mathcal{A})$ is contained in $D^+(\mathcal{A})$ if and only if $H^i(E) = 0$ for all $i \ll 0$. Similar statements hold for D^- and D^+ .*

Proof. Hint: use truncation functors. See Derived Categories, Lemma 13.11.6. \square

Lemma 44.83.3. *Morphisms between objects in the derived category.*

- (1) *Let $I^\bullet \in \mathrm{Comp}^+(\mathcal{A})$ with I^n injective for all $n \in \mathbf{Z}$. Then*

$$\mathrm{Hom}_{D(\mathcal{A})}(K^\bullet, I^\bullet) = \mathrm{Hom}_{K(\mathcal{A})}(K^\bullet, I^\bullet).$$

(2) Let $P^\bullet \in \text{Comp}^-(\mathcal{A})$ with P^n is projective for all $n \in \mathbf{Z}$. Then

$$\text{Hom}_{D(\mathcal{A})}(P^\bullet, K^\bullet) = \text{Hom}_{K(\mathcal{A})}(P^\bullet, K^\bullet).$$

(3) If \mathcal{A} has enough injectives and $\mathcal{I} \subset \mathcal{A}$ is the additive subcategory of injectives, then $D^+(\mathcal{A}) \cong K^+(\mathcal{I})$ (as triangulated categories).

(4) If \mathcal{A} has enough projectives and $\mathcal{P} \subset \mathcal{A}$ is the additive subcategory of projectives, then $D^-(\mathcal{A}) \cong K^-(\mathcal{P})$.

Proof. Omitted. □

Definition 44.83.4. Let $F : \mathcal{A} \rightarrow \mathcal{B}$ be a left exact functor and assume that \mathcal{A} has enough injectives. We define the *total right derived functor of F* as the functor $RF : D^+(\mathcal{A}) \rightarrow D^+(\mathcal{B})$ fitting into the diagram

$$\begin{array}{ccc} D^+(\mathcal{A}) & \xrightarrow{RF} & D^+(\mathcal{B}) \\ \uparrow & & \uparrow \\ K^+(\mathcal{I}) & \xrightarrow{F} & K^+(\mathcal{B}). \end{array}$$

This is possible since the left vertical arrow is invertible by the previous lemma. Similarly, let $G : \mathcal{A} \rightarrow \mathcal{B}$ be a right exact functor and assume that \mathcal{A} has enough projectives. We define the *total right derived functor of G* as the functor $LG : D^-(\mathcal{A}) \rightarrow D^-(\mathcal{B})$ fitting into the diagram

$$\begin{array}{ccc} D^-(\mathcal{A}) & \xrightarrow{LG} & D^-(\mathcal{B}) \\ \uparrow & & \uparrow \\ K^-(\mathcal{P}) & \xrightarrow{G} & K^-(\mathcal{B}). \end{array}$$

This is possible since the left vertical arrow is invertible by the previous lemma.

Remark 44.83.5. In these cases, it is true that $R^i F(K^\bullet) = H^i(RF(K^\bullet))$, where the left hand side is defined to be i th homology of the complex $F(K^\bullet)$.

44.84. Filtered derived category

It turns out we have to do it all again and build the filtered derived category also.

Definition 44.84.1. Let \mathcal{A} be an abelian category.

(1) Let $\text{Fil}(\mathcal{A})$ be the category of filtered objects (A, F) of \mathcal{A} , where F is a filtration of the form

$$A \supset \dots \supset F^n A \supset F^{n+1} A \supset \dots \supset 0.$$

This is an additive category.

(2) We denote $\text{Fil}^f(\mathcal{A})$ the full subcategory of $\text{Fil}(\mathcal{A})$ whose objects (A, F) have finite filtration. This is also an additive category.

(3) An object $I \in \text{Fil}^f(\mathcal{A})$ is called *filtered injective* (respectively *projective*) provided that $\text{gr}^p(I) = \text{gr}_F^p(I) = F^p I / F^{p+1} I$ is injective (resp. projective) in \mathcal{A} for all p .

(4) The category of complexes $\text{Comp}(\text{Fil}^f(\mathcal{A})) \supset \text{Comp}^+(\text{Fil}^f(\mathcal{A}))$ and its homotopy category $K(\text{Fil}^f(\mathcal{A})) \supset K^+(\text{Fil}^f(\mathcal{A}))$ are defined as before.

- (5) A morphism $\alpha : K^\bullet \rightarrow L^\bullet$ of complexes in $\text{Comp}(\text{Fil}^f(\mathcal{A}))$ is called a *filtered quasi-isomorphism* provided that

$$\text{gr}^p(\alpha) : \text{gr}^p(K^\bullet) \rightarrow \text{gr}^p(L^\bullet)$$

is a quasi-isomorphism for all $p \in \mathbf{Z}$.

- (6) We define $DF(\mathcal{A})$ (resp. $DF^+(\mathcal{A})$) by inverting the filtered quasi-isomorphisms in $K(\text{Fil}^f(\mathcal{A}))$ (resp. $K^+(\text{Fil}^f(\mathcal{A}))$).

Lemma 44.84.2. *If \mathcal{A} has enough injectives, then $DF^+(\mathcal{A}) \cong K^+(\mathcal{I})$, where \mathcal{I} is the full additive subcategory of $\text{Fil}^f(\mathcal{A})$ consisting of filtered injective objects. Similarly, if \mathcal{A} has enough projectives, then $DF^-(\mathcal{A}) \cong K^+(\mathcal{P})$, where \mathcal{P} is the full additive subcategory of $\text{Fil}^f(\mathcal{A})$ consisting of filtered projective objects.*

Proof. Omitted. □

44.85. Filtered derived functors

And then there are the filtered derived functors.

Definition 44.85.1. Let $T : \mathcal{A} \rightarrow \mathcal{B}$ be a left exact functor and assume that \mathcal{A} has enough injectives. Define $RT : DF^+(\mathcal{A}) \rightarrow DF^+(\mathcal{B})$ to fit in the diagram

$$\begin{array}{ccc} DF^+(\mathcal{A}) & \xrightarrow{RT} & DF^+(\mathcal{B}) \\ \uparrow & & \uparrow \\ K^+(\mathcal{I}) & \xrightarrow{T} & K^+(\text{Fil}^f(\mathcal{B})). \end{array}$$

This is well-defined by the previous lemma. Let $G : \mathcal{A} \rightarrow \mathcal{B}$ be a right exact functor and assume that \mathcal{A} has enough projectives. Define $LG : DF^-(\mathcal{A}) \rightarrow DF^-(\mathcal{B})$ to fit in the diagram

$$\begin{array}{ccc} DF^-(\mathcal{A}) & \xrightarrow{LG} & DF^-(\mathcal{B}) \\ \uparrow & & \uparrow \\ K^-(\mathcal{P}) & \xrightarrow{G} & K^-(\text{Fil}^f(\mathcal{B})). \end{array}$$

Again, this is well-defined by the previous lemma. The functors RT , resp. LG , are called the *filtered derived functor* of T , resp. G .

Proposition 44.85.2. *In the situation above, we have*

$$\text{gr}^p \circ RT = RT \circ \text{gr}^p$$

where the RT on the left is the filtered derived functor while the one on the right is the total derived functor. That is, there is a commuting diagram

$$\begin{array}{ccc} DF^+(\mathcal{A}) & \xrightarrow{RT} & DF^+(\mathcal{B}) \\ \text{gr}^p \downarrow & & \downarrow \text{gr}^p \\ D^+(\mathcal{A}) & \xrightarrow{RT} & D^+(\mathcal{B}). \end{array}$$

Proof. Omitted. □

Given $K^\bullet \in DF^+(\mathcal{B})$, we get a spectral sequence

$$E_1^{p,q} = H^{p+q}(\text{gr}^p K^\bullet) \Rightarrow H^{p+q}(\text{forget fil}(K^\bullet)).$$

44.86. Application of filtered complexes

Let \mathcal{A} be an abelian category with enough injectives, and $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$ a short exact sequence in \mathcal{A} . Consider $\widetilde{M} \in \text{Fil}^f(\mathcal{A})$ to be M along with the filtration defined by

$$F^1 M = L, \quad F^n M = M \text{ for } n \leq 0, \text{ and } F^n M = 0 \text{ for } n \geq 2.$$

By definition, we have

$$\text{forget filt}(\widetilde{M}) = M, \quad \text{gr}^0(\widetilde{M}) = N, \quad \text{gr}^1(\widetilde{M}) = L$$

and $\text{gr}^n(\widetilde{M}) = 0$ for all other $n \neq 0, 1$. Let $T : \mathcal{A} \rightarrow \mathcal{B}$ be a left exact functor. Assume that \mathcal{A} has enough injectives. Then $RT(\widetilde{M}) \in DF^+(\mathcal{B})$ is a filtered complex with

$$\text{gr}^p(RT(\widetilde{M})) \stackrel{\text{qis}}{\cong} \begin{cases} 0 & \text{if } p \neq 0, 1, \\ RT(N) & \text{if } p = 0, \\ RT(L) & \text{if } p = 1. \end{cases}$$

and $\text{forget filt}(RT(\widetilde{M})) \stackrel{\text{qis}}{\cong} RT(M)$. The spectral sequence applied to $RT(\widetilde{M})$ gives

$$E_1^{p,q} = R^{p+q}T(\text{gr}^p(\widetilde{M})) \Rightarrow R^{p+q}T(\text{forget filt}(\widetilde{M})).$$

Unwinding the spectral sequence gives us the long exact sequence

$$\begin{array}{ccccccc} 0 & \longrightarrow & T(L) & \longrightarrow & T(M) & \longrightarrow & T(N) \\ & & & & & & \searrow \\ & & & & R^1T(L) & \longrightarrow & R^1T(M) & \longrightarrow & \dots \end{array}$$

This will be used as follows. Let X/k be a scheme of finite type. Let \mathcal{F} be a flat constructible $\mathbf{Z}/\ell^n\mathbf{Z}$ -module. Then we want to show that the trace

$$\text{Tr}(\pi_X^* | R\Gamma_c(X_{\bar{k}}, \mathcal{F})) \in \mathbf{Z}/\ell^n\mathbf{Z}$$

is additive on short exact sequences. To see this, it will not be enough to work with $R\Gamma_c(X_{\bar{k}}, -) \in D^+(\mathbf{Z}/\ell^n\mathbf{Z})$, but we will have to use the filtered derived category.

44.87. Perfectness

Let Λ be a (possibly noncommutative) ring, Mod_Λ the category of left Λ -modules, $K(\Lambda) = K(\text{Mod}_\Lambda)$ its homotopy category, and $D(\Lambda) = D(\text{Mod}_\Lambda)$ the derived category.

Definition 44.87.1. We denote by $K_{\text{perf}}(\Lambda)$ the category whose objects are bounded complexes of finite projective Λ -modules, and whose morphisms are morphisms of complexes up to homotopy. The functor $K_{\text{perf}}(\Lambda) \rightarrow D(\Lambda)$ is fully faithful (Derived Categories, Lemma 13.19.8). Denote $D_{\text{perf}}(\Lambda)$ its essential image. An object of $D(\Lambda)$ is called *perfect* if it is in $D_{\text{perf}}(\Lambda)$.

Proposition 44.87.2. *Let $K \in D_{\text{perf}}(\Lambda)$ and $f \in \text{End}_{D(\Lambda)}(K)$. Then the trace $\text{Tr}(f) \in \Lambda^{\natural}$ is well defined.*

Proof. We will use Derived Categories, Lemma 13.19.8 without further mention in this proof. Let P^\bullet be a bounded complex of finite projective Λ -modules and

let $\alpha : P^\bullet \rightarrow K$ be an isomorphism in $D(\Lambda)$. Then $\alpha^{-1} \circ f \circ \alpha$ corresponds to a morphism of complexes $f^\bullet : P^\bullet \rightarrow P^\bullet$ well defined up to homotopy. Set

$$\text{Tr}(f) = \sum_i (-1)^i \text{Tr}(f^i : P^i \rightarrow P^i) \in \Lambda^{\natural}.$$

Given P^\bullet and α , this is independent of the choice of f^\bullet . Namely, any other choice is of the form $\tilde{f}^\bullet = f^\bullet + dh + hd$ for some $h^i : P^i \rightarrow P^{i-1} (i \in \mathbf{Z})$. But

$$\begin{aligned} \text{Tr}(dh) &= \sum_i (-1)^i \text{Tr}(P^i \xrightarrow{dh} P^i) \\ &= \sum_i (-1)^i \text{Tr}(P^{i-1} \xrightarrow{hd} P^{i-1}) \\ &= - \sum_i (-1)^{i-1} \text{Tr}(P^{i-1} \xrightarrow{hd} P^{i-1}) \\ &= -\text{Tr}(hd) \end{aligned}$$

and so $\sum_i (-1)^i \text{Tr}((dh+hd)|_{P^i}) = 0$. Furthermore, this is independent of the choice of (P^\bullet, α) : suppose (Q^\bullet, β) is another choice. The compositions

$$Q^\bullet \xrightarrow{\beta} K \xrightarrow{\alpha^{-1}} P^\bullet \quad \text{and} \quad P^\bullet \xrightarrow{\alpha} K \xrightarrow{\beta^{-1}} Q^\bullet$$

are representable by morphisms of complexes γ_1^\bullet and γ_2^\bullet respectively, such that $\gamma_1^\bullet \circ \gamma_2^\bullet$ is homotopic to the identity. Thus, the morphism of complexes $\gamma_2^\bullet \circ f^\bullet \circ \gamma_1^\bullet : Q^\bullet \rightarrow Q^\bullet$ represents the morphism $\beta^{-1} \circ f \circ \beta$ in $D(\Lambda)$. Now

$$\begin{aligned} \text{Tr}(\gamma_2^\bullet \circ f^\bullet \circ \gamma_1^\bullet|_{Q^\bullet}) &= \text{Tr}(\gamma_1^\bullet \circ \gamma_2^\bullet \circ f^\bullet|_{P^\bullet}) \\ &= \text{Tr}(f^\bullet|_{P^\bullet}) \end{aligned}$$

by the fact that $\gamma_1^\bullet \circ \gamma_2^\bullet$ is homotopic to the identity and the independence of the choice of f^\bullet we saw above. □

44.88. Filtrations and perfect complexes

We now present a filtered version of the category of perfect complexes. An object (M, F) of $\text{Fil}^f(\text{Mod}_\Lambda)$ is called *filtered finite projective* if for all p , $\text{gr}_F^p(M)$ is finite and projective. We then consider the homotopy category $KF_{\text{perf}}(\Lambda)$ of bounded complexes of filtered finite projective objects of $\text{Fil}^f(\text{Mod}_\Lambda)$. We have a diagram of categories

$$\begin{array}{ccc} KF(\Lambda) & \supset & KF_{\text{perf}}(\Lambda) \\ \downarrow & & \downarrow \\ DF(\Lambda) & \supset & DF_{\text{perf}}(\Lambda) \end{array}$$

where the vertical functor on the right is fully faithful and the category $DF_{\text{perf}}(\Lambda)$ is its essential image, as before.

Lemma 44.88.1 (Additivity). *Let $K \in DF_{\text{perf}}(\Lambda)$ and $f \in \text{End}_{DF}(K)$. Then*

$$\text{Tr}(f|_K) = \sum_{p \in \mathbf{Z}} \text{Tr}(f|_{\text{gr}^p K}).$$

Proof. By Proposition 44.87.2, we may assume we have a bounded complex P^\bullet of filtered finite projectives of $\text{Fil}^f(\text{Mod}_\Lambda)$ and a map $f^\bullet : P^\bullet \rightarrow P^\bullet$ in $\text{Comp}(\text{Fil}^f(\text{Mod}_\Lambda))$. So the lemma follows from the following result, which proof is left to the reader. □

Lemma 44.88.2. *Let $P \in \text{Fil}^f(\text{Mod}_\Lambda)$ be filtered finite projective, and $f : P \rightarrow P$ an endomorphism in $\text{Fil}^f(\text{Mod}_\Lambda)$. Then*

$$\text{Tr}(f|_P) = \sum_p \text{Tr}(f|_{\text{gr}^p(P)}).$$

Proof. Omitted. □

44.89. Characterizing perfect objects

For the commutative case see More on Algebra, Sections 15.50, 15.51, and 15.56.

Definition 44.89.1. Let Λ be a (possibly noncommutative) ring. An object $K \in D(\Lambda)$ has *finite Tor-dimension* if there exist $a, b \in \mathbf{Z}$ such that for any right Λ -module N , we have $H^i(N \otimes_\Lambda^L K) = 0$ for all $i \notin [a, b]$.

This in particular means that $K \in D^b(\Lambda)$ as we see by taking $N = \Lambda$.

Lemma 44.89.2. *Let Λ be a left noetherian ring and $K \in D(\Lambda)$. Then K is perfect if and only if the two following conditions hold:*

- (1) K has finite Tor-dimension, and
- (2) for all $i \in \mathbf{Z}$, $H^i(K)$ is a finite Λ -module.

Proof. See More on Algebra, Lemma 15.56.2 for the proof in the commutative case. □

The reader is strongly urged to try and prove this. The proof relies on the fact that a finite module on a finitely left-presented ring is flat if and only if it is projective.

Remark 44.89.3. A variant of this lemma is to consider a Noetherian scheme X and the category $D_{\text{perf}}(\mathcal{O}_X)$ of complexes which are locally quasi-isomorphic to a finite complex of finite locally free \mathcal{O}_X -modules. Objects K of $D_{\text{perf}}(\mathcal{O}_X)$ can be characterized by having coherent cohomology sheaves and bounded tor dimension.

44.90. Complexes with constructible cohomology

Let Λ be a ring. Let X a scheme. Let $K(X, \Lambda)$ the homotopy category of sheaves of Λ -modules on $X_{\text{étale}}$. Denote $D(X, \Lambda)$ the corresponding derived category. We denote by $D^b(X, \Lambda)$ (respectively D^+ , D^-) the full subcategory of bounded (resp. above, below) complexes in $D(X, \Lambda)$.

Definition 44.90.1. Let X be a scheme. Let Λ be a Noetherian ring. We denote $D_c(X, \Lambda)$ the full subcategory of $D(X, \Lambda)$ of complexes whose cohomology sheaves are constructible sheaves of Λ -modules.

This definition makes sense by Lemma 44.69.6 and Derived Categories, Section 13.13. Thus we see that $D_c(X, \Lambda)$ is a strictly full, saturated triangulated subcategory of $D_c(X, \Lambda)$.

Lemma 44.90.2. *Let Λ be a Noetherian ring. If $j : U \rightarrow X$ is an étale morphism of schemes, then*

- (1) $K|_U \in D_c(U, \Lambda)$ if $K \in D_c(X, \Lambda)$, and
- (2) $j_!M \in D_c(X, \Lambda)$ if $M \in D_c(U, \Lambda)$ and the morphism j is quasi-compact and quasi-separated.

Proof. The first assertion is clear. The second follows from the fact that $j_!$ is exact and Lemma 44.71.1. □

Lemma 44.90.3. *Let Λ be a Noetherian ring. Let $f : X \rightarrow Y$ be a morphism of schemes. If $K \in D_c(Y, \Lambda)$ then $Lf^*K \in D_c(X, \Lambda)$.*

Proof. This follows as $f^{-1} = f^*$ is exact and Lemma 44.69.5. □

Lemma 44.90.4. *Let X be a quasi-compact and quasi-separated scheme. Let Λ be a Noetherian ring. Let $K \in D(X, \Lambda)$ and $b \in \mathbf{Z}$ such that $H^b(K)$ is constructible. Then there exist a sheaf \mathcal{F} which is a finite direct sum of $j_{U!}\underline{\Lambda}$ with $U \in \text{Ob}(X_{\text{étale}})$ affine and a map $\mathcal{F}[-b] \rightarrow K$ in $D(X, \Lambda)$ inducing a surjection $\mathcal{F} \rightarrow H^b(K)$.*

Proof. Represent K by a complex \mathcal{K}^\bullet of sheaves of Λ -modules. Consider the surjection

$$\text{Ker}(\mathcal{K}^b \rightarrow \mathcal{K}^{b+1}) \longrightarrow H^b(K)$$

By Modules on Sites, Lemma 18.29.5 we may choose a surjection $\bigoplus_{i \in I} j_{U_i!}\underline{\Lambda} \rightarrow \text{Ker}(\mathcal{K}^b \rightarrow \mathcal{K}^{b+1})$ with U_i affine. For $I' \subset I$ finite, denote $\mathcal{H}_{I'} \subset H^b(K)$ the image of $\bigoplus_{i \in I'} j_{U_i!}\underline{\Lambda}$. By Lemma 44.69.9 we see that $\mathcal{H}_{I'} = H^b(K)$ for some $I' \subset I$ finite. The lemma follows taking $\mathcal{F} = \bigoplus_{i \in I'} j_{U_i!}\underline{\Lambda}$. □

Lemma 44.90.5. *Let X be a quasi-compact and quasi-separated scheme. Let Λ be a Noetherian ring. Let $K \in D^-(X, \Lambda)$. Then the following are equivalent*

- (1) K is in $D_c(X, \Lambda)$,
- (2) K can be represented by a bounded above complex whose terms are finite direct sums of $j_{U!}\underline{\Lambda}$ with $U \in \text{Ob}(X_{\text{étale}})$ affine,
- (3) K can be represented by a bounded above complex of flat constructible sheaves of Λ -modules.

Proof. It is clear that (2) implies (3) and that (3) implies (1). Assume K is in $D_c^-(X, \Lambda)$. Say $H^i(K) = 0$ for $i > b$. By induction on a we will construct a complex $\mathcal{F}^a \rightarrow \dots \rightarrow \mathcal{F}^b$ such that each \mathcal{F}^i is a finite direct sum of $j_{U!}\underline{\Lambda}$ with $U \in \text{Ob}(X_{\text{étale}})$ affine and a map $\mathcal{F}^\bullet \rightarrow K$ which induces an isomorphism $H^i(\mathcal{F}^\bullet) \rightarrow H^i(K)$ for $i > a$ and a surjection $H^a(\mathcal{F}^\bullet) \rightarrow H^a(K)$. For $a = b$ this can be done by Lemma 44.90.4. Given such a datum choose a distinguished triangle

$$\mathcal{F}^\bullet \rightarrow K \rightarrow L \rightarrow \mathcal{F}^\bullet[1]$$

Then we see that $H^i(L) = 0$ for $i \geq a$. Choose $\mathcal{F}^{a-1}[-a+1] \rightarrow L$ as in Lemma 44.90.4. The composition $\mathcal{F}^{a-1}[-a+1] \rightarrow L \rightarrow \mathcal{F}^\bullet$ corresponds to a map $\mathcal{F}^{a-1} \rightarrow \mathcal{F}^a$ such that the composition with $\mathcal{F}^a \rightarrow \mathcal{F}^{a+1}$ is zero. By TR4 we obtain a map

$$(\mathcal{F}^{a-1} \rightarrow \dots \rightarrow \mathcal{F}^b) \rightarrow K$$

in $D(X, \Lambda)$. This finishes the induction step and the proof of the lemma. □

Lemma 44.90.6. *Let X be a scheme. Let Λ be a Noetherian ring. Let $K, L \in D_c^-(X, \Lambda)$. Then $K \otimes_\Lambda^L L$ is in $D_c^-(X, \Lambda)$.*

Proof. This follows from Lemmas 44.90.5 and 44.69.7. □

Definition 44.90.7. Let X be a scheme. Let Λ be a Noetherian ring. We denote $D_{ctf}(X, \Lambda)$ the full subcategory of $D_c(X, \Lambda)$ consisting of objects having locally finite tor dimension.

This is a strictly full, saturated triangulated subcategory of $D_c(X, \Lambda)$ and $D(X, \Lambda)$. By our conventions, see Cohomology on Sites, Definition 21.35.1, we see that

$$D_{ctf}(X, \Lambda) \subset D^b(X, \Lambda)$$

if X is quasi-compact. A good way to think about objects of $D_{ctf}(X, \Lambda)$ is given in Lemma 44.90.9.

Remark 44.90.8. The situation with objects of $D_{ctf}(X, \Lambda)$ is different from $D_{perf}(\mathcal{O}_X)$ in Remark 44.89.3. Namely, it can happen that a complex of \mathcal{O}_X -modules is locally quasi-isomorphic to a finite complex of finite locally free \mathcal{O}_X -modules, without being globally quasi-isomorphic to a bounded complex of locally free \mathcal{O}_X -modules. The following lemma shows this does not happen for D_{ctf} on a Noetherian scheme.

Lemma 44.90.9. *Let Λ be a Noetherian ring. Let X be a quasi-compact and quasi-separated scheme. Let $K \in D(X, \Lambda)$. The following are equivalent*

- (1) $K \in D_{ctf}(X, \Lambda)$, and
- (2) K can be represented by a finite complex of constructible flat sheaves of Λ -modules.

In fact, if K has tor amplitude in $[a, b]$ then we can represent K by a complex $\mathcal{F}^a \rightarrow \dots \rightarrow \mathcal{F}^b$ with \mathcal{F}^p a constructible flat sheaf of Λ -modules.

Proof. It is clear that a finite complex of constructible flat sheaves of Λ -modules has finite tor dimension. It is also clear that it is an object of $D_c(X, \Lambda)$. Thus we see that (2) implies (1).

Assume (1). Choose $a, b \in \mathbf{Z}$ such that $H^i(K \otimes_{\Lambda}^{\mathbf{L}} \mathcal{G}) = 0$ if $i \notin [a, b]$ for all sheaves of Λ -modules \mathcal{G} . We will prove the final assertion holds by induction on $b - a$. If $a = b$, then $K = H^a(K)[-a]$ is a flat constructible sheaf and the result holds. Next, assume $b > a$. Represent K by a complex \mathcal{K}^\bullet of sheaves of Λ -modules. Consider the surjection

$$\text{Ker}(\mathcal{K}^b \rightarrow \mathcal{K}^{b+1}) \longrightarrow H^b(K)$$

By Lemma 44.71.6 we can find finitely many affine schemes U_i étale over X and a surjection $\bigoplus j_{U_i!} \underline{\Lambda}_{U_i} \rightarrow H^b(K)$. After replacing U_i by standard étale coverings $\{U_{ij} \rightarrow U_i\}$ we may assume this surjection lifts to a map $\mathcal{F} = \bigoplus j_{U_i!} \underline{\Lambda}_{U_i} \rightarrow \text{Ker}(\mathcal{K}^b \rightarrow \mathcal{K}^{b+1})$. This map determines a distinguished triangle

$$\mathcal{F}[-b] \rightarrow K \rightarrow L \rightarrow \mathcal{F}[-b + 1]$$

in $D(X, \Lambda)$. Since $D_{ctf}(X, \Lambda)$ is a triangulated subcategory we see that L is in it too. In fact L has tor amplitude in $[a, b - 1]$ as \mathcal{F} surjects onto $H^b(K)$ (details omitted). By induction hypothesis we can find a finite complex $\mathcal{F}^a \rightarrow \dots \rightarrow \mathcal{F}^{b-1}$ of flat constructible sheaves of Λ -modules representing L . The map $L \rightarrow \mathcal{F}[-b + 1]$ corresponds to a map $\mathcal{F}^b \rightarrow \mathcal{F}$ annihilating the image of $\mathcal{F}^{b-1} \rightarrow \mathcal{F}^b$. Then it follows from axiom TR3 that K is represented by the complex

$$\mathcal{F}^a \rightarrow \dots \rightarrow \mathcal{F}^{b-1} \rightarrow \mathcal{F}^b$$

which finishes the proof. □

Remark 44.90.10. Let Λ be a Noetherian ring. Let X be a scheme. For a bounded complex K^\bullet of constructible flat Λ -modules on $X_{\text{étale}}$ each stalk K_x^p is a finite projective Λ -module. Hence the stalks of the complex are perfect complexes of Λ -modules.

Remark 44.90.11. Lemma 44.90.9 can be used to prove that if $f : X \rightarrow Y$ is a separated, finite type morphism of schemes and Y is noetherian, then $Rf_!$ induces a functor $D_{ctf}(X, \Lambda) \rightarrow D_{ctf}(Y, \Lambda)$. We only need this fact in the case where Y is the spectrum of a field and X is a curve.

Lemma 44.90.12. *Let Λ be a Noetherian ring. If $j : U \rightarrow X$ is an étale morphism of schemes, then*

- (1) $K|_U \in D_{ctf}(U, \Lambda)$ if $K \in D_{ctf}(X, \Lambda)$, and
- (2) $j_!M \in D_{ctf}(X, \Lambda)$ if $M \in D_{ctf}(U, \Lambda)$ and the morphism j is quasi-compact and quasi-separated.

Proof. Perhaps the easiest way to prove this lemma is to reduce to the case where X is affine and then apply Lemma 44.90.9 to translate it into a statement about finite complexes of flat constructible sheaves of Λ -modules where the result follows from Lemma 44.71.1. \square

Lemma 44.90.13. *Let Λ be a Noetherian ring. Let $f : X \rightarrow Y$ be a morphism of schemes. If $K \in D_{ctf}(Y, \Lambda)$ then $Lf^*K \in D_{ctf}(X, \Lambda)$.*

Proof. Apply Lemma 44.90.9 to reduce this to a question about finite complexes of flat constructible sheaves of Λ -modules. Then the statement follows as $f^{-1} = f^*$ is exact and Lemma 44.69.5. \square

Lemma 44.90.14. *Let X be a connected scheme. Let Λ be a Noetherian ring. Let $K \in D_{ctf}(X, \Lambda)$ have locally constant cohomology sheaves. Then there exists a finite complex of finite projective Λ -modules M^\bullet and an étale covering $\{U_i \rightarrow X\}$ such that $K|_{U_i} \cong \underline{M^\bullet}|_{U_i}$ in $D(U_i, \Lambda)$.*

Proof. Choose an étale covering $\{U_i \rightarrow X\}$ such that $K|_{U_i}$ is constant, say $K|_{U_i} \cong \underline{M_i^\bullet}|_{U_i}$ for some finite complex of finite Λ -modules M_i^\bullet . See Cohomology on Sites, Lemma 21.40.1. Observe that $U_i \times_X U_j$ is empty if M_i^\bullet is not isomorphic to M_j^\bullet in $D(\Lambda)$. For each complex of Λ -modules M^\bullet let $I_{M^\bullet} = \{i \in I \mid M_i^\bullet \cong M^\bullet \text{ in } D(\Lambda)\}$. As étale morphisms are open we see that $U_{M^\bullet} = \bigcup_{i \in I_{M^\bullet}} \text{Im}(U_i \rightarrow X)$ is an open subset of X . Then $X = \coprod U_{M^\bullet}$ is a disjoint open covering of X . As X is connected only one U_{M^\bullet} is nonempty. As K is in $D_{ctf}(X, \Lambda)$ we see that M^\bullet is a perfect complex of Λ -modules, see More on Algebra, Lemma 15.56.2. Hence we may assume M^\bullet is a finite complex of finite projective Λ -modules. \square

44.91. Cohomology of nice complexes

The following is a special case of a more general result about compactly supported cohomology of objects of $D_{ctf}(X, \Lambda)$.

Proposition 44.91.1. *Let X be a projective curve over a field k , Λ a finite ring and $K \in D_{ctf}(X, \Lambda)$. Then $R\Gamma(X_{\bar{k}}, K) \in D_{perf}(\Lambda)$.*

Sketch of proof. The first step is to show:

- (1) *The cohomology of $R\Gamma(X_{\bar{k}}, K)$ is bounded.*

Consider the spectral sequence

$$H^i(X_{\bar{k}}, \underline{H}^j(K)) \Rightarrow H^{i+j}(R\Gamma(X_{\bar{k}}, K)).$$

Since K is bounded and Λ is finite, the sheaves $\underline{H}^j(K)$ are torsion. Moreover, $X_{\bar{k}}$ has finite cohomological dimension, so the left-hand side is nonzero for finitely many i and j only. Therefore, so is the right-hand side.

(2) *The cohomology groups $H^{i+j}(R\Gamma(X_{\bar{k}}, K))$ are finite.*

Since the sheaves $\underline{H}^j(K)$ are constructible, the groups $H^i(X_{\bar{k}}, \underline{H}^j(K))$ are finite (Section 44.75) so it follows by the spectral sequence again.

(3) *$R\Gamma(X_{\bar{k}}, K)$ has finite Tor-dimension.*

Let N be a right Λ -module (in fact, since Λ is finite, it suffices to assume that N is finite). By the projection formula (change of module),

$$N \otimes_{\Lambda}^{\mathbf{L}} R\Gamma(X_{\bar{k}}, K) = R\Gamma(X_{\bar{k}}, N \otimes_{\Lambda}^{\mathbf{L}} K).$$

Therefore,

$$H^i(N \otimes_{\Lambda}^{\mathbf{L}} R\Gamma(X_{\bar{k}}, K)) = H^i(R\Gamma(X_{\bar{k}}, N \otimes_{\Lambda}^{\mathbf{L}} K)).$$

Now consider the spectral sequence

$$H^i(X_{\bar{k}}, \underline{H}^j(N \otimes_{\Lambda}^{\mathbf{L}} K)) \Rightarrow H^{i+j}(R\Gamma(X_{\bar{k}}, N \otimes_{\Lambda}^{\mathbf{L}} K)).$$

Since K has finite Tor-dimension, $\underline{H}^j(N \otimes_{\Lambda}^{\mathbf{L}} K)$ vanishes universally for j small enough, and the left-hand side vanishes whenever $i < 0$. Therefore $R\Gamma(X_{\bar{k}}, K)$ has finite Tor-dimension, as claimed. So it is a perfect complex by Lemma 44.89.2. \square

44.92. Lefschetz numbers

The fact that the total cohomology of a constructible complex of finite tor dimension is a perfect complex is the key technical reason why cohomology behaves well, and allows us to define rigorously the traces occurring in the trace formula.

Definition 44.92.1. Let Λ be a finite ring, X a projective curve over a finite field k and $K \in D_{ctf}(X, \Lambda)$ (for instance $K = \underline{\Lambda}$). There is a canonical map $c_K : \pi_X^{-1}K \rightarrow K$, and its base change $c_K|_{X_{\bar{k}}}$ induces an action denoted π_X^* on the perfect complex $R\Gamma(X_{\bar{k}}, K|_{X_{\bar{k}}})$. The *global Lefschetz number* of K is the trace $\text{Tr}(\pi_X^*|_{R\Gamma(X_{\bar{k}}, K)})$ of that action. It is an element of Λ^{\natural} .

Definition 44.92.2. With Λ, X, k, K as in Definition 44.92.1. Since $K \in D_{ctf}(X, \Lambda)$, for any geometric point \bar{x} of X , the complex $K_{\bar{x}}$ is a perfect complex (in $D_{perf}(\Lambda)$). As we have seen in Section 44.80, the Frobenius π_X acts on $K_{\bar{x}}$. The *local Lefschetz number* of K is the sum

$$\sum_{x \in X(k)} \text{Tr}(\pi_X|_{K_{\bar{x}}})$$

which is again an element of Λ^{\natural} .

At last, we can formulate precisely the trace formula.

Theorem 44.92.3 (Lefschetz Trace Formula). *Let X be a projective curve over a finite field k , Λ a finite ring and $K \in D_{ctf}(X, \Lambda)$. Then the global and local Lefschetz numbers of K are equal, i.e.,*

$$(44.92.3.1) \quad \text{Tr}(\pi_X^*|_{R\Gamma(X_{\bar{k}}, K)}) = \sum_{x \in X(k)} \text{Tr}(\pi_X|_{K_{\bar{x}}})$$

in Λ^{\natural} .

Proof. See discussion below. \square

We will use, rather than prove, the trace formula. Nevertheless, we will give quite a few details of the proof of the theorem as given in [Del77] (some of the things that are not adequately explained are listed in Section 44.99).

We only stated the formula for curves, and in some weak sense it is a consequence of the following result.

Theorem 44.92.4 (Weil). *Let C be a nonsingular projective curve over an algebraically closed field k , and $\varphi : C \rightarrow C$ a k -endomorphism of C distinct from the identity. Let $V(\varphi) = \Delta_C \cdot \Gamma_\varphi$, where Δ_C is the diagonal, Γ_φ is the graph of φ , and the intersection number is taken on $C \times C$. Let $J = \text{Pic}_{C/k}^0$ be the jacobian of C and denote $\varphi^* : J \rightarrow J$ the action induced by φ by taking pullbacks. Then*

$$V(\varphi) = 1 - \text{Tr}_J(\varphi^*) + \text{deg } \varphi.$$

Proof. The number $V(\varphi)$ is the number of fixed points of φ , it is equal to

$$V(\varphi) = \sum_{c \in |C|: \varphi(c)=c} m_{\text{Fix}(\varphi)}(c)$$

where $m_{\text{Fix}(\varphi)}(c)$ is the multiplicity of c as a fixed point of φ , namely the order or vanishing of the image of a local uniformizer under $\varphi - \text{id}_C$. Proofs of this theorem can be found in [Lan02] and [Wei48]. □

Example 44.92.5. Let $C = E$ be an elliptic curve and $\varphi = [n]$ be multiplication by n . Then $\varphi^* = \varphi^t$ is multiplication by n on the jacobian, so it has trace $2n$ and degree n^2 . On the other hand, the fixed points of φ are the points $p \in E$ such that $np = p$, which is the $(n - 1)$ -torsion, which has cardinality $(n - 1)^2$. So the theorem reads

$$(n - 1)^2 = 1 - 2n + n^2.$$

Jacobians. We now discuss without proofs the correspondence between a curve and its jacobian which is used in Weil’s proof. Let C be a nonsingular projective curve over an algebraically closed field k and choose a base point $c_0 \in C(k)$. Denote by $A^1(C \times C)$ (or $\text{Pic}(C \times C)$, or $\text{CaCl}(C \times C)$) the abelian group of codimension 1 divisors of $C \times C$. Then

$$A^1(C \times C) = \text{pr}_1^*(A^1(C)) \oplus \text{pr}_2^*(A^1(C)) \oplus R$$

where

$$R = \{Z \in A^1(C \times C) \mid Z|_{C \times \{c_0\}} \sim_{\text{rat}} 0 \text{ and } Z|_{\{c_0\} \times C} \sim_{\text{rat}} 0\}.$$

In other words, R is the subgroup of line bundles which pull back to the trivial one under either projection. Then there is a canonical isomorphism of abelian groups $R \cong \text{End}(J)$ which maps a divisor Z in R to the endomorphism

$$\begin{array}{ccc} J & \rightarrow & J \\ [\mathcal{O}_C(D)] & \mapsto & (\text{pr}_1|_Z)_*(\text{pr}_2|_Z)^*(D). \end{array}$$

The aforementioned correspondence is the following. We denote by σ the automorphism of $C \times C$ that switches the factors.

End(J)	R
composition of α, β	$\text{pr}_{13*}(\text{pr}_{12}^*(\alpha) \circ \text{pr}_{23}^*(\beta))$
id_J	$\Delta_C - \{c_0\} \times C - C \times \{c_0\}$
φ^*	$\Gamma_\varphi - C \times \{\varphi(c_0)\} - \sum_{\varphi(c)=c_0} \{c\} \times C$
the trace form $\alpha, \beta \mapsto \text{Tr}(\alpha\beta)$	$\alpha, \beta \mapsto -\int_{C \times C} \alpha \cdot \sigma^* \beta$
the Rosati involution $\alpha \mapsto \alpha^\dagger$	$\alpha \mapsto \sigma^* \alpha$
positivity of Rosati $\text{Tr}(\alpha\alpha^\dagger) > 0$	Hodge index theorem on $C \times C$ $-\int_{C \times C} \alpha \sigma^* \alpha > 0.$

In fact, in light of the Kunnetth formula, the subgroup R corresponds to the 1, 1 hodge classes in $H^1(C) \otimes H^1(C)$.

Weil’s proof. Using this correspondence, we can prove the trace formula. We have

$$\begin{aligned} V(\varphi) &= \int_{C \times C} \Gamma_\varphi \cdot \Delta \\ &= \int_{C \times C} \Gamma_\varphi \cdot (\Delta_C - \{c_0\} \times C - C \times \{c_0\}) + \int_{C \times C} \Gamma_\varphi \cdot (\{c_0\} \times C + C \times \{c_0\}). \end{aligned}$$

Now, on the one hand

$$\int_{C \times C} \Gamma_\varphi \cdot (\{c_0\} \times C + C \times \{c_0\}) = 1 + \text{deg } \varphi$$

and on the other hand, since R is the orthogonal of the ample divisor $\{c_0\} \times C + C \times \{c_0\}$,

$$\begin{aligned} &\int_{C \times C} \Gamma_\varphi \cdot (\Delta_C - \{c_0\} \times C - C \times \{c_0\}) \\ &= \int_{C \times C} \left(\Gamma_\varphi - C \times \{\varphi(c_0)\} - \sum_{\varphi(c)=c_0} \{c\} \times C \right) \cdot (\Delta_C - \{c_0\} \times C - C \times \{c_0\}) \\ &= -\text{Tr}_J(\varphi^* \circ \text{id}_J). \end{aligned}$$

Recapitulating, we have

$$V(\varphi) = 1 - \text{Tr}_J(\varphi^*) + \text{deg } \varphi$$

which is the trace formula.

Lemma 44.92.6. *Consider the situation of Theorem 44.92.4 and let ℓ be a prime number invertible in k . Then*

$$\sum_{i=0}^2 (-1)^i \text{Tr}(\varphi^* |_{H^i(C, \underline{\mathbf{Z}}/\ell^n \mathbf{Z})}) = V(\varphi) \pmod{\ell^n}.$$

Sketch of proof. Observe first that the assumption makes sense because $H^i(C, \underline{\mathbf{Z}}/\ell^n \mathbf{Z})$ is a free $\mathbf{Z}/\ell^n \mathbf{Z}$ -module for all i . The trace of φ^* on the 0th degree cohomology is

1. The choice of a primitive ℓ^n th root of unity in k gives an isomorphism

$$H^i(C, \underline{\mathbf{Z}}/\ell^n \mathbf{Z}) \cong H^i(C, \mu_{\ell^n})$$

compatibly with the action of the geometric Frobenius. On the other hand, $H^1(C, \mu_{\ell^n}) = J[\ell^n]$. Therefore,

$$\begin{aligned} \text{Tr}(\varphi^* |_{H^1(C, \underline{\mathbf{Z}}/\ell^n \mathbf{Z})}) &= \text{Tr}_J(\varphi^*) \pmod{\ell^n} \\ &= \text{Tr}_{\mathbf{Z}/\ell^n \mathbf{Z}}(\varphi^* : J[\ell^n] \rightarrow J[\ell^n]). \end{aligned}$$

Moreover, $H^2(C, \mu_{\ell^n}) = \text{Pic}(C)/\ell^n \text{Pic}(C) \cong \mathbf{Z}/\ell^n \mathbf{Z}$ where φ^* is multiplication by $\text{deg } \varphi$. Hence

$$\text{Tr}(\varphi^* |_{H^2(C, \underline{\mathbf{Z}}/\ell^n \mathbf{Z})}) = \text{deg } \varphi.$$

Thus we have

$$\sum_{i=0}^2 (-1)^i \text{Tr}(\varphi^* |_{H^i(C, \underline{\mathbf{Z}}/\ell^n \mathbf{Z})}) = 1 - \text{Tr}_J(\varphi^*) + \text{deg } \varphi \pmod{\ell^n}$$

and the corollary follows from Theorem 44.92.4. □

An alternative way to prove this corollary is to show that

$$X \mapsto H^*(X, \mathbf{Q}_\ell) = \mathbf{Q}_\ell \otimes \lim_n H^*(X, \mathbf{Z}/\ell^n \mathbf{Z})$$

defines a Weil cohomology theory on smooth projective varieties over k . Then the trace formula

$$V(\varphi) = \sum_{i=0}^2 (-1)^i \text{Tr}(\varphi^* |_{H^i(C, \mathbf{Q}_\ell)})$$

is a formal consequence of the axioms (it's an exercise in linear algebra, the proof is the same as in the topological case).

44.93. Preliminaries and sorites

Notation: We fix the notation for this section. We denote by A a commutative ring, Λ a (possibly noncommutative) ring with a ring map $A \rightarrow \Lambda$ which image lies in the center of Λ . We let G be a finite group, Γ a *monoid extension of G by \mathbf{N}* , meaning that there is an exact sequence

$$1 \rightarrow G \rightarrow \tilde{\Gamma} \rightarrow \mathbf{Z} \rightarrow 1$$

and Γ consists of those elements of $\tilde{\Gamma}$ which image is nonnegative. Finally, we let P be an $A[\Gamma]$ -module which is finite and projective as an $A[G]$ -module, and M a $\Lambda[\Gamma]$ -module which is finite and projective as a Λ -module.

Our goal is to compute the trace of $1 \in \mathbf{N}$ acting over Λ on the coinvariants of G on $P \otimes_A M$, that is, the number

$$\text{Tr}_\Lambda (1; (P \otimes_A M)_G) \in \Lambda^\natural.$$

The element $1 \in \mathbf{N}$ will correspond to the Frobenius.

Lemma 44.93.1. *Let $e \in G$ denote the neutral element. The map*

$$\begin{aligned} \Lambda[G] &\longrightarrow \Lambda^{\natural} \\ \sum \lambda_g \cdot g &\longmapsto \lambda_e \end{aligned}$$

factors through $\Lambda[G]^{\natural}$. We denote $\varepsilon : \Lambda[G]^{\natural} \rightarrow \Lambda^{\natural}$ the induced map.

Proof. We have to show the map annihilates commutators. One has

$$\left(\sum \lambda_g g \right) \left(\sum \mu_g g \right) - \left(\sum \mu_g g \right) \left(\sum \lambda_g g \right) = \sum_g \left(\sum_{g_1 g_2 = g} \lambda_{g_1} \mu_{g_2} - \mu_{g_1} \lambda_{g_2} \right) g$$

The coefficient of e is

$$\sum_g (\lambda_g \mu_{g^{-1}} - \mu_g \lambda_{g^{-1}}) = \sum_g (\lambda_g \mu_{g^{-1}} - \mu_{g^{-1}} \lambda_g)$$

which is a sum of commutators, hence it is zero in Λ^{\natural} . \square

Definition 44.93.2. Let $f : P \rightarrow P$ be an endomorphism of a finite projective $\Lambda[G]$ -module P . We define

$$\mathrm{Tr}_{\Lambda}^G(f; P) := \varepsilon(\mathrm{Tr}_{\Lambda[G]}(f; P))$$

to be the G -trace of f on P .

Lemma 44.93.3. *Let $f : P \rightarrow P$ be an endomorphism of the finite projective $\Lambda[G]$ -module P . Then*

$$\mathrm{Tr}_{\Lambda}(f; P) = \#G \cdot \mathrm{Tr}_{\Lambda}^G(f; P).$$

Proof. By additivity, reduce to the case $P = \Lambda[G]$. In that case, f is given by right multiplication by some element $\sum \lambda_g \cdot g$ of $\Lambda[G]$. In the basis $(g)_{g \in G}$, the matrix of f has coefficient $\lambda_{g_2^{-1}g_1}$ in the (g_1, g_2) position. In particular, all diagonal coefficients are λ_e , and there are $\#G$ such coefficients. \square

Lemma 44.93.4. *The map $A \rightarrow \Lambda$ defines an A -module structure on Λ^{\natural} .*

Proof. This is clear. \square

Lemma 44.93.5. *Let P be a finite projective $A[G]$ -module and M a $\Lambda[G]$ -module, finite projective as a Λ -module. Then $P \otimes_A M$ is a finite projective $\Lambda[G]$ -module, for the structure induced by the diagonal action of G .*

Note that $P \otimes_A M$ is naturally a Λ -module since M is. Explicitly, together with the diagonal action this reads

$$\left(\sum \lambda_g g \right) (p \otimes m) = \sum gp \otimes \lambda_g gm.$$

Proof. For any $\Lambda[G]$ -module N one has

$$\mathrm{Hom}_{\Lambda[G]}(P \otimes_A M, N) = \mathrm{Hom}_{A[G]}(P, \mathrm{Hom}_{\Lambda}(M, N))$$

where the G -action on $\mathrm{Hom}_{\Lambda}(M, N)$ is given by $(g \cdot \varphi)(m) = g\varphi(g^{-1}m)$. Now it suffices to observe that the right-hand side is a composition of exact functors, because of the projectivity of P and M . \square

Lemma 44.93.6. *With assumptions as in Lemma 44.93.5, let $u \in \mathrm{End}_{A[G]}(P)$ and $v \in \mathrm{End}_{\Lambda[G]}(M)$. Then*

$$\mathrm{Tr}_{\Lambda}^G(u \otimes v; P \otimes_A M) = \mathrm{Tr}_A^G(u; P) \cdot \mathrm{Tr}_{\Lambda}(v; M).$$

Sketch of proof. Reduce to the case $P = A[G]$. In that case, u is right multiplication by some element $a = \sum a_g g$ of $A[G]$, which we write $u = R_a$. There is an isomorphism of $\Lambda[G]$ -modules

$$\begin{aligned} \varphi : A[G] \otimes_A M &\cong (A[G] \otimes_A M)' \\ g \otimes m &\longmapsto g \otimes g^{-1}m \end{aligned}$$

where $(A[G] \otimes_A M)'$ has the module structure given by the left G -action, together with the Λ -linearity on M . This transport of structure changes $u \otimes v$ into $\sum_g a_g R_g \otimes g^{-1}v$. In other words,

$$\varphi \circ (u \otimes v) \circ \varphi^{-1} = \sum_g a_g R_g \otimes g^{-1}v.$$

Working out explicitly both sides of the equation, we have to show

$$\mathrm{Tr}_\Lambda^G \left(\sum_g a_g R_g \otimes g^{-1}v \right) = a_e \cdot \mathrm{Tr}_\Lambda(v; M).$$

This is done by showing that

$$\mathrm{Tr}_\Lambda^G (a_g R_g \otimes g^{-1}v) = \begin{cases} 0 & \text{if } g \neq e \\ a_e \mathrm{Tr}_\Lambda(v; M) & \text{if } g = e \end{cases}$$

by reducing to $M = \Lambda$. □

Notation: Consider the monoid extension $1 \rightarrow G \rightarrow \Gamma \rightarrow \mathbf{N} \rightarrow 1$ and let $\gamma \in \Gamma$. Then we write $Z_\gamma = \{g \in G \mid g\gamma = \gamma g\}$.

Lemma 44.93.7. *Let P be a $\Lambda[\Gamma]$ -module, finite and projective as a $\Lambda[G]$ -module, and $\gamma \in \Gamma$. Then*

$$\mathrm{Tr}_\Lambda(\gamma, P) = \#Z_\gamma \cdot \mathrm{Tr}_\Lambda^{Z_\gamma}(\gamma, P).$$

Proof. This follows readily from Lemma 44.93.3. □

Lemma 44.93.8. *Let P be an $A[\Gamma]$ -module, finite projective as $A[G]$ -module. Let M be a $\Lambda[\Gamma]$ -module, finite projective as a Λ -module. Then*

$$\mathrm{Tr}_\Lambda^{Z_\gamma}(\gamma, P \otimes_A M) = \mathrm{Tr}_\Lambda^{Z_\gamma}(\gamma, P) \cdot \mathrm{Tr}_\Lambda(\gamma, M).$$

Proof. This follows directly from Lemma 44.93.6. □

Lemma 44.93.9. *Let P be a $\Lambda[\Gamma]$ -module, finite projective as $\Lambda[G]$ -module. Then the coinvariants $P_G = \Lambda \otimes_{\Lambda[G]} P$ form a finite projective Λ -module, endowed with an action of $\Gamma/G = \mathbf{N}$. Moreover, we have*

$$\mathrm{Tr}_\Lambda(1; P_G) = \sum'_{\gamma \mapsto 1} \mathrm{Tr}_\Lambda^{Z_\gamma}(\gamma, P)$$

where $\sum'_{\gamma \mapsto 1}$ means taking the sum over the G -conjugacy classes in Γ .

Sketch of proof. We first prove this after multiplying by $\#G$.

$$\#G \cdot \mathrm{Tr}_\Lambda(1; P_G) = \mathrm{Tr}_\Lambda \left(\sum_{\gamma \mapsto 1} \gamma, P_G \right) = \mathrm{Tr}_\Lambda \left(\sum_{\gamma \mapsto 1} \gamma, P \right)$$

where the second equality follows by considering the commutative triangle

$$\begin{array}{ccccc} PG & \xhookrightarrow{a} & P & \twoheadrightarrow{b} & P_G \\ & & \searrow & \swarrow & \\ & & & c & \end{array}$$

where a is the canonical inclusion, b the canonical surjection and $c = \sum_{\gamma \mapsto 1} \gamma$. Then we have

$$\left(\sum_{\gamma \mapsto 1} \gamma\right)|_P = a \circ c \circ b \quad \text{and} \quad \left(\sum_{\gamma \mapsto 1} \gamma\right)|_{P_G} = b \circ a \circ c$$

hence they have the same trace. We then have

$$\#G \cdot \text{Tr}_\Lambda(1; P_G) = \sum'_{\gamma \mapsto 1} \frac{\#G}{\#Z_\gamma} \text{Tr}_\Lambda(\gamma, P) = \#G \sum'_{\gamma \mapsto 1} \text{Tr}_\Lambda^{Z_\gamma}(\gamma, P).$$

To finish the proof, reduce to case Λ torsion-free by some universality argument. See [Del77] for details. \square

Remark 44.93.10. Let us try to illustrate the content of the formula of Lemma 44.93.8. Suppose that Λ , viewed as a trivial Γ -module, admits a finite resolution $0 \rightarrow P_r \rightarrow \dots \rightarrow P_1 \rightarrow P_0 \rightarrow \Lambda \rightarrow 0$ by some $\Lambda[\Gamma]$ -modules P_i which are finite and projective as $\Lambda[G]$ -modules. In that case

$$H_*((P_\bullet)_G) = \text{Tor}_*^{\Lambda[G]}(\Lambda, \Lambda) = H_*(G, \Lambda)$$

and

$$\text{Tr}_\Lambda^{Z_\gamma}(\gamma, P_\bullet) = \frac{1}{\#Z_\gamma} \text{Tr}_\Lambda(\gamma, P_\bullet) = \frac{1}{\#Z_\gamma} \text{Tr}(\gamma, \Lambda) = \frac{1}{\#Z_\gamma}.$$

Therefore, Lemma 44.93.8 says

$$\text{Tr}_\Lambda(1, P_G) = \text{Tr}(1|_{H_*(G, \Lambda)}) = \sum'_{\gamma \mapsto 1} \frac{1}{\#Z_\gamma}.$$

This can be interpreted as a point count on the stack BG . If $\Lambda = \mathbf{F}_\ell$ with ℓ prime to $\#G$, then $H_*(G, \Lambda)$ is \mathbf{F}_ℓ in degree 0 (and 0 in other degrees) and the formula reads

$$1 = \sum_{\substack{\sigma\text{-conjugacy} \\ \text{classes}(\gamma)}} \frac{1}{\#Z_\gamma} \pmod{\ell}.$$

This is in some sense a “trivial” trace formula for G . Later we will see that (44.92.3.1) can in some cases be viewed as a highly nontrivial trace formula for a certain type of group, see Section 44.108.

44.94. Proof of the trace formula

Theorem 44.94.1. *Let k be a finite field and X a finite type, separated scheme of dimension at most 1 over k . Let Λ be a finite ring whose cardinality is prime to that of k , and $K \in D_{ctf}(X, \Lambda)$. Then*

$$(44.94.1.1) \quad \text{Tr}(\pi_X^*|_{R\Gamma_c(X_{\bar{k}}, K)}) = \sum_{x \in X(k)} \text{Tr}(\pi_x|_{K_{\bar{x}}})$$

in Λ^{\natural} .

Please see Remark 44.94.2 for some remarks on the statement. Notation: For short, we write

$$T'(X, K) = \sum_{x \in X(k)} \text{Tr}(\pi_x|_{K_{\bar{x}}})$$

for the right-hand side of (44.94.1.1) and

$$T''(X, K) = \text{Tr}(\pi_x^*|_{R\Gamma_c(X_{\bar{k}}, K)})$$

for the left-hand side.

Proof of Theorem 44.94.1. The proof proceeds in a number of steps.

Step 1. Let $j : \mathcal{U} \hookrightarrow X$ be an open immersion with complement $Y = X - \mathcal{U}$ and $i : Y \hookrightarrow X$. Then $T''(X, K) = T''(\mathcal{U}, j^{-1}K) + T''(Y, i^{-1}K)$ and $T'(X, K) = T'(\mathcal{U}, j^{-1}K) + T'(Y, i^{-1}K)$.

This is clear for T' . For T'' use the exact sequence

$$0 \rightarrow j_!j^{-1}K \rightarrow K \rightarrow i_*i^{-1}K \rightarrow 0$$

to get a filtration on K . This gives rise to an object $\tilde{K} \in DF(X, \Lambda)$ whose graded pieces are $j_!j^{-1}K$ and $i_*i^{-1}K$, both of which lie in $D_{ctf}(X, \Lambda)$. Then, by filtered derived abstract nonsense (INSERT REFERENCE), $R\Gamma_c(X_{\bar{k}}, K) \in DF_{perf}(\Lambda)$, and it comes equipped with π_X^* in $DF_{perf}(\Lambda)$. By the discussion of traces on filtered complexes (INSERT REFERENCE) we get

$$\begin{aligned} \text{Tr}(\pi_X^*|_{R\Gamma_c(X_{\bar{k}}, K)}) &= \text{Tr}(\pi_X^*|_{R\Gamma_c(X_{\bar{k}}, j_!j^{-1}K)}) + \text{Tr}(\pi_X^*|_{R\Gamma_c(X_{\bar{k}}, i_*i^{-1}K)}) \\ &= T''(\mathcal{U}, i^{-1}K) + T''(Y, i^{-1}K). \end{aligned}$$

Step 2. The theorem holds if $\dim X \leq 0$.

Indeed, in that case

$$R\Gamma_c(X_{\bar{k}}, K) = R\Gamma(X_{\bar{k}}, K) = \Gamma(X_{\bar{k}}, K) = \bigoplus_{\bar{x} \in X_{\bar{k}}} K_{\bar{x}} \leftarrow \pi_X^*.$$

Since the fixed points of $\pi_X : X_{\bar{k}} \rightarrow X_{\bar{k}}$ are exactly the points $\bar{x} \in X_{\bar{k}}$ which lie over a k -rational point $x \in X(k)$ we get

$$\text{Tr}(\pi_X^*|_{R\Gamma_c(X_{\bar{k}}, K)}) = \sum_{x \in X(k)} \text{Tr}(\pi_{\bar{x}}|_{K_{\bar{x}}}).$$

Step 3. It suffices to prove the equality $T'(\mathcal{U}, \mathcal{F}) = T''(\mathcal{U}, \mathcal{F})$ in the case where

- \mathcal{U} is a smooth irreducible affine curve over k ,
- $\mathcal{U}(k) = \emptyset$,
- $K = \mathcal{F}$ is a finite locally constant sheaf of Λ -modules on \mathcal{U} whose stalk(s) are finite projective Λ -modules, and
- Λ is killed by a power of a prime ℓ and $\ell \in k^*$.

Indeed, because of Step 2, we can throw out any finite set of points. But we have only finitely many rational points, so we may assume there are none⁷. We may assume that \mathcal{U} is smooth irreducible and affine by passing to irreducible components and throwing away the bad points if necessary. The assumptions of \mathcal{F} come from unwinding the definition of $D_{ctf}(X, \Lambda)$ and those on Λ from considering its primary decomposition.

For the remainder of the proof, we consider the situation

$$\begin{array}{ccc} \mathcal{V} & \longrightarrow & Y \\ f \downarrow & & \downarrow \bar{f} \\ \mathcal{U} & \longrightarrow & X \end{array}$$

where \mathcal{U} is as above, f is a finite étale Galois covering, \mathcal{V} is connected and the horizontal arrows are projective completions. Denoting $G = \text{Aut}(\mathcal{V}|\mathcal{U})$, we also assume (as we may) that $f^{-1}\mathcal{F} = \underline{M}$ is constant, where the module $M = \Gamma(\mathcal{V}, f^{-1}\mathcal{F})$ is a

⁷At this point, there should be an evil laugh in the background.

$\Lambda[G]$ -module which is finite and projective over Λ . This corresponds to the trivial monoid extension

$$1 \rightarrow G \rightarrow \Gamma = G \times \mathbf{N} \rightarrow \mathbf{N} \rightarrow 1.$$

In that context, using the reductions above, we need to show that $T''(\mathcal{U}, \mathcal{F}) = 0$.

Step 4. *There is a natural action of G on $f_*f^{-1}\mathcal{F}$ and the trace map $f_*f^{-1}\mathcal{F} \rightarrow \mathcal{F}$ defines an isomorphism*

$$(f_*f^{-1}\mathcal{F}) \otimes_{\Lambda[G]} \Lambda = (f_*f^{-1}\mathcal{F})_G \cong \mathcal{F}.$$

To prove this, simply unwind everything at a geometric point.

Step 5. *Let $A = \mathbf{Z}/\ell^n\mathbf{Z}$ with $n \gg 0$. Then $f_*f^{-1}\mathcal{F} \cong (f_*\underline{A}) \otimes_{\underline{A}} \underline{M}$ with diagonal G -action.*

Step 6. *There is a canonical isomorphism $(f_*\underline{A} \otimes_{\underline{A}} \underline{M}) \otimes_{\Lambda[G]} \underline{\Lambda} \cong \mathcal{F}$.*

In fact, this is a derived tensor product, because of the projectivity assumption on \mathcal{F} .

Step 7. *There is a canonical isomorphism*

$$R\Gamma_c(\mathcal{U}_{\bar{k}}, \mathcal{F}) = (R\Gamma_c(\mathcal{U}_{\bar{k}}, f_*A) \otimes_A^{\mathbf{L}} M) \otimes_{\Lambda[G]}^{\mathbf{L}} \Lambda,$$

compatible with the action of $\pi_{\mathcal{U}}^$.*

This comes from the universal coefficient theorem, i.e., the fact that $R\Gamma_c$ commutes with $\otimes^{\mathbf{L}}$, and the flatness of \mathcal{F} as a Λ -module.

We have

$$\begin{aligned} \mathrm{Tr}(\pi_{\mathcal{U}}^*|_{R\Gamma_c(\mathcal{U}_{\bar{k}}, \mathcal{F})}) &= \sum'_{g \in G} \mathrm{Tr}_{\Lambda}^{Z_g} \left((g, \pi_{\mathcal{U}}^*)|_{R\Gamma_c(\mathcal{U}_{\bar{k}}, f_*A) \otimes_A^{\mathbf{L}} M} \right) \\ &= \sum'_{g \in G} \mathrm{Tr}_A^{Z_g} \left((g, \pi_{\mathcal{U}}^*)|_{R\Gamma_c(\mathcal{U}_{\bar{k}}, f_*A)} \right) \cdot \mathrm{Tr}_{\Lambda}(g|M) \end{aligned}$$

where Γ acts on $R\Gamma_c(\mathcal{U}_{\bar{k}}, \mathcal{F})$ by G and $(e, 1)$ acts via $\pi_{\mathcal{U}}^*$. So the monoidal extension is given by $\Gamma = G \times \mathbf{N} \rightarrow \mathbf{N}$, $\gamma \mapsto 1$. The first equality follows from Lemma 44.93.9 and the second from Lemma 44.93.8.

Step 8. *It suffices to show that $\mathrm{Tr}_A^{Z_g}((g, \pi_{\mathcal{U}}^*)|_{R\Gamma_c(\mathcal{U}_{\bar{k}}, f_*A)}) \in A$ maps to zero in Λ .*

Recall that

$$\begin{aligned} \#Z_g \cdot \mathrm{Tr}_A^{Z_g}((g, \pi_{\mathcal{U}}^*)|_{R\Gamma_c(\mathcal{U}_{\bar{k}}, f_*A)}) &= \mathrm{Tr}_A((g, \pi_{\mathcal{U}}^*)|_{R\Gamma_c(\mathcal{U}_{\bar{k}}, f_*A)}) \\ &= \mathrm{Tr}_A((g^{-1}\pi_{\mathcal{V}})^*|_{R\Gamma_c(\mathcal{V}_{\bar{k}}, A)}). \end{aligned}$$

The first equality is Lemma 44.93.7, the second is the Leray spectral sequence, using the finiteness of f and the fact that we are only taking traces over A . Now since $A = \mathbf{Z}/\ell^n\mathbf{Z}$ with $n \gg 0$ and $\#Z_g = \ell^a$ for some (fixed) a , it suffices to show the following result.

Step 9. *We have $\mathrm{Tr}_A((g^{-1}\pi_{\mathcal{V}})^*|_{R\Gamma_c(\mathcal{V}, A)}) = 0$ in A .*

By additivity again, we have

$$\begin{aligned} \mathrm{Tr}_A((g^{-1}\pi_{\mathcal{V}})^*|_{R\Gamma_c(\mathcal{V}_{\bar{k}}, A)}) + \mathrm{Tr}_A((g^{-1}\pi_{\mathcal{V}})^*|_{R\Gamma_c(Y-\mathcal{V})_{\bar{k}}, A}) \\ = \mathrm{Tr}_A((g^{-1}\pi_Y)^*|_{R\Gamma(Y_{\bar{k}}, A)}) \end{aligned}$$

The latter trace is the number of fixed points of $g^{-1}\pi_Y$ on Y , by Weil’s trace formula Theorem 44.92.4. Moreover, by the 0-dimensional case already proven in step 2,

$$\mathrm{Tr}_A((g^{-1}\pi_Y)^*|_{R\Gamma_c(Y-\mathcal{V})_{\bar{k}},A})$$

is the number of fixed points of $g^{-1}\pi_Y$ on $(Y - \mathcal{V})_{\bar{k}}$. Therefore,

$$\mathrm{Tr}_A((g^{-1}\pi_Y)^*|_{R\Gamma_c(\mathcal{V})_{\bar{k}},A})$$

is the number of fixed points of $g^{-1}\pi_Y$ on $\mathcal{V}_{\bar{k}}$. But there are no such points: if $\bar{y} \in Y_{\bar{k}}$ is fixed under $g^{-1}\pi_Y$, then $\bar{f}(\bar{y}) \in X_{\bar{k}}$ is fixed under π_X . But \mathcal{U} has no k -rational point, so we must have $\bar{f}(\bar{y}) \in (X - \mathcal{U})_{\bar{k}}$ and so $\bar{y} \notin \mathcal{V}_{\bar{k}}$, a contradiction. This finishes the proof. \square

Remark 44.94.2. Remarks on Theorem 44.94.1.

- (1) This formula holds in any dimension. By a dévissage lemma (which uses proper base change etc.) it reduces to the current statement – in that generality.
- (2) The complex $R\Gamma_c(X_{\bar{k}}, K)$ is defined by choosing an open immersion $j : X \hookrightarrow \bar{X}$ with \bar{X} projective over k of dimension at most 1 and setting

$$R\Gamma_c(X_{\bar{k}}, K) := R\Gamma(\bar{X}_{\bar{k}}, j_!K).$$

This is independent of the choice of \bar{X} follows from (insert reference here). We define $H_c^i(X_{\bar{k}}, K)$ to be the i th cohomology group of $R\Gamma_c(X_{\bar{k}}, K)$.

Remark 44.94.3. Even though all we did are reductions and mostly algebra, the trace formula Theorem 44.94.1 is much stronger than Weil’s geometric trace formula (Theorem 44.92.4) because it applies to coefficient systems (sheaves), not merely constant coefficients.

44.95. Applications

OK, having indicated the proof of the trace formula, let’s try to use it for something.

44.96. On \mathbf{l} -adic sheaves

Definition 44.96.1. Let X be a noetherian scheme. A \mathbf{Z}_ℓ -sheaf on X , or simply a ℓ -adic sheaf is an inverse system $\{\mathcal{F}_n\}_{n \geq 1}$ where

- (1) \mathcal{F}_n is a constructible $\mathbf{Z}/\ell^n\mathbf{Z}$ -module on $X_{\acute{e}tale}$, and
- (2) the transition maps $\mathcal{F}_{n+1} \rightarrow \mathcal{F}_n$ induce isomorphisms $\mathcal{F}_{n+1} \otimes_{\mathbf{Z}/\ell^{n+1}\mathbf{Z}} \mathbf{Z}/\ell^n\mathbf{Z} \cong \mathcal{F}_n$.

We say that \mathcal{F} is *lisse* if each \mathcal{F}_n is locally constant. A *morphism* of such is merely a morphism of inverse systems.

Lemma 44.96.2. *Let $\{\mathcal{G}_n\}_{n \geq 1}$ be an inverse system of constructible $\mathbf{Z}/\ell^n\mathbf{Z}$ -modules. Suppose that for all $k \geq 1$, the maps*

$$\mathcal{G}_{n+1}/\ell^k\mathcal{G}_{n+1} \rightarrow \mathcal{G}_n/\ell^k\mathcal{G}_n$$

are isomorphisms for all $n \gg 0$ (where the bound possibly depends on k). In other words, assume that the system $\{\mathcal{G}_n/\ell^k\mathcal{G}_n\}_{n \geq 1}$ is eventually constant, and call \mathcal{F}_k the corresponding sheaf. Then the system $\{\mathcal{F}_k\}_{k \geq 1}$ forms a \mathbf{Z}_ℓ -sheaf on X .

Proof. The proof is obvious. \square

Lemma 44.96.3. *The category of \mathbf{Z}_ℓ -sheaves on X is abelian.*

Proof. Let $\Phi = \{\varphi_n\}_{n \geq 1} : \{\mathcal{F}_n\} \rightarrow \{\mathcal{G}_n\}$ be a morphism of \mathbf{Z}_ℓ -sheaves. Set

$$\text{Coker}(\Phi) = \left\{ \text{Coker} \left(\mathcal{F}_n \xrightarrow{\varphi_n} \mathcal{G}_n \right) \right\}_{n \geq 1}$$

and $\text{Ker}(\Phi)$ is the result of Lemma 44.96.2 applied to the inverse system

$$\left\{ \bigcap_{m \geq n} \text{Im}(\text{Ker}(\varphi_m) \rightarrow \text{Ker}(\varphi_n)) \right\}_{n \geq 1}.$$

That this defines an abelian category is left to the reader. □

Example 44.96.4. Let $X = \text{Spec}(\mathbf{C})$ and $\Phi : \mathbf{Z}_\ell \rightarrow \mathbf{Z}_\ell$ be multiplication by ℓ . More precisely,

$$\Phi = \left\{ \mathbf{Z}/\ell^n \mathbf{Z} \xrightarrow{\ell} \mathbf{Z}/\ell^n \mathbf{Z} \right\}_{n \geq 1}.$$

To compute the kernel, we consider the inverse system

$$\dots \rightarrow \mathbf{Z}/\ell \mathbf{Z} \xrightarrow{0} \mathbf{Z}/\ell \mathbf{Z} \xrightarrow{0} \mathbf{Z}/\ell \mathbf{Z}.$$

Since the images are always zero, $\text{Ker}(\Phi)$ is zero as a system.

Remark 44.96.5. If $\mathcal{F} = \{\mathcal{F}_n\}_{n \geq 1}$ is a \mathbf{Z}_ℓ -sheaf on X and \bar{x} is a geometric point then $M_n = \{\mathcal{F}_{n, \bar{x}}\}$ is an inverse system of finite $\mathbf{Z}/\ell^n \mathbf{Z}$ -modules such that $M_{n+1} \rightarrow M_n$ is surjective and $M_n = M_{n+1}/\ell^n M_{n+1}$. It follows that

$$M = \lim_n M_n = \lim \mathcal{F}_{n, \bar{x}}$$

is a finite \mathbf{Z}_ℓ -module. Indeed, $M/\ell M = M_1$ is finite over \mathbf{F}_ℓ , so by Nakayama M is finite over \mathbf{Z}_ℓ . Therefore, $M \cong \mathbf{Z}_\ell^{\oplus r} \oplus \bigoplus_{i=1}^t \mathbf{Z}_\ell/\ell^{e_i} \mathbf{Z}_\ell$ for some $r, t \geq 0, e_i \geq 1$. The module $M = \mathcal{F}_{\bar{x}}$ is called the *stalk* of \mathcal{F} at \bar{x} .

Definition 44.96.6. A \mathbf{Z}_ℓ -sheaf \mathcal{F} is *torsion* if $\ell^n : \mathcal{F} \rightarrow \mathcal{F}$ is the zero map for some n . The abelian category of \mathbf{Q}_ℓ -sheaves on X is the quotient of the abelian category of \mathbf{Z}_ℓ -sheaves by the Serre subcategory of torsion sheaves. In other words, its objects are \mathbf{Z}_ℓ -sheaves on X , and if \mathcal{F}, \mathcal{G} are two such, then

$$\text{Hom}_{\mathbf{Q}_\ell}(\mathcal{F}, \mathcal{G}) = \text{Hom}_{\mathbf{Z}_\ell}(\mathcal{F}, \mathcal{G}) \otimes_{\mathbf{Z}_\ell} \mathbf{Q}_\ell.$$

We denote by $\mathcal{F} \mapsto \mathcal{F} \otimes \mathbf{Q}_\ell$ the quotient functor (right adjoint to the inclusion). If $\mathcal{F} = \mathcal{F}' \otimes \mathbf{Q}_\ell$ where \mathcal{F}' is a \mathbf{Z}_ℓ -sheaf and \bar{x} is a geometric point, then the *stalk* of \mathcal{F} at \bar{x} is $\mathcal{F}_{\bar{x}} = \mathcal{F}'_{\bar{x}} \otimes \mathbf{Q}_\ell$.

Remark 44.96.7. Since a \mathbf{Z}_ℓ -sheaf is only defined on a noetherian scheme, it is torsion if and only if its stalks are torsion.

Definition 44.96.8. If X is a separated scheme of finite type over an algebraically closed field k and $\mathcal{F} = \{\mathcal{F}_n\}_{n \geq 1}$ is a \mathbf{Z}_ℓ -sheaf on X , then we define

$$H^i(X, \mathcal{F}) := \lim_n H^i(X, \mathcal{F}_n) \quad \text{and} \quad H_c^i(X, \mathcal{F}) := \lim_n H_c^i(X, \mathcal{F}_n).$$

If $\mathcal{F} = \mathcal{F}' \otimes \mathbf{Q}_\ell$ for a \mathbf{Z}_ℓ -sheaf \mathcal{F}' then we set

$$H_c^i(X, \mathcal{F}) := H_c^i(X, \mathcal{F}') \otimes_{\mathbf{Z}_\ell} \mathbf{Q}_\ell.$$

We call these the *ℓ -adic cohomology* of X with coefficients \mathcal{F} .

44.97. L-functions

Definition 44.97.1. Let X be a scheme of finite type over a finite field k . Let Λ be a finite ring of order prime to the characteristic of k and \mathcal{F} a constructible flat Λ -module on $X_{\acute{e}tale}$. Then we set

$$L(X, \mathcal{F}) := \prod_{x \in |X|} \det(1 - \pi_x^* T^{\deg x}|_{\mathcal{F}_{\bar{x}}})^{-1} \in \Lambda[[T]]$$

where $|X|$ is the set of closed points of X , $\deg x = [\kappa(x) : k]$ and \bar{x} is a geometric point lying over x . This definition clearly generalizes to the case where \mathcal{F} is replaced by a $K \in D_{ctf}(X, \Lambda)$. We call this the *L-function of \mathcal{F}* .

Remark 44.97.2. Intuitively, T should be thought of as $T = t^f$ where $p^f = \#k$. The definitions are then independent of the size of the ground field.

Definition 44.97.3. Now assume that \mathcal{F} is a \mathbf{Q}_ℓ -sheaf on X . In this case we define

$$L(X, \mathcal{F}) := \prod_{x \in |X|} \det(1 - \pi_x^* T^{\deg x}|_{\mathcal{F}_{\bar{x}}})^{-1} \in \mathbf{Q}_\ell[[T]].$$

Note that this product converges since there are finitely many points of a given degree. We call this the *L-function of \mathcal{F}* .

44.98. Cohomological interpretation

This is how Grothendieck interpreted the *L-function*.

Theorem 44.98.1 (Finite Coefficients). *Let X be a scheme of finite type over a finite field k . Let Λ be a finite ring of order prime to the characteristic of k and \mathcal{F} a constructible flat Λ -module on $X_{\acute{e}tale}$. Then*

$$L(X, \mathcal{F}) = \det(1 - \pi_X^* T|_{R\Gamma_c(X_{\bar{k}}, \mathcal{F})})^{-1} \in \Lambda[[T]].$$

Proof. Omitted. □

Thus far, we don't even know whether each cohomology group $H_c^i(X_{\bar{k}}, \mathcal{F})$ is free.

Theorem 44.98.2 (Adic sheaves). *Let X be a scheme of finite type over a finite field k , and \mathcal{F} a \mathbf{Q}_ℓ -sheaf on X . Then*

$$L(X, \mathcal{F}) = \prod_i \det(1 - \pi_X^* T|_{H_c^i(X_{\bar{k}}, \mathcal{F})})^{(-1)^{i+1}} \in \mathbf{Q}_\ell[[T]].$$

Proof. This is sketched below. □

Remark 44.98.3. Since we have only developed some theory of traces and not of determinants, Theorem 44.98.1 is harder to prove than Theorem 44.98.2. We will only prove the latter, for the former see [Del77]. Observe also that there is no version of this theorem more general for \mathbf{Z}_ℓ coefficients since there is no ℓ -torsion.

We reduce the proof of Theorem 44.98.2 to a trace formula. Since \mathbf{Q}_ℓ has characteristic 0, it suffices to prove the equality after taking logarithmic derivatives. More

precisely, we apply $T \frac{d}{dT} \log$ to both sides. We have on the one hand

$$\begin{aligned} T \frac{d}{dT} \log L(X, \mathcal{F}) &= T \frac{d}{dT} \log \prod_{x \in |X|} \det(1 - \pi_x^* T^{\deg x} |_{\mathcal{F}_{\bar{x}}})^{-1} \\ &= \sum_{x \in |X|} T \frac{d}{dT} \log(\det(1 - \pi_x^* T^{\deg x} |_{\mathcal{F}_{\bar{x}}})^{-1}) \\ &= \sum_{x \in |X|} \deg x \sum_{n \geq 1} \text{Tr}((\pi_x^n)^* |_{\mathcal{F}_{\bar{x}}}) T^{n \deg x} \end{aligned}$$

where the last equality results from the formula

$$T \frac{d}{dT} \log \left(\det(1 - fT|_M)^{-1} \right) = \sum_{n \geq 1} \text{Tr}(f^n|_M) T^n$$

which holds for any commutative ring Λ and any endomorphism f of a finite projective Λ -module M . On the other hand, we have

$$\begin{aligned} T \frac{d}{dT} \log \left(\prod_i \det(1 - \pi_X^* T |_{H_c^i(X_{\bar{k}}, \mathcal{F})})^{(-1)^{i+1}} \right) \\ = \sum_i (-1)^i \sum_{n \geq 1} \text{Tr}((\pi_X^n)^* |_{H_c^i(X_{\bar{k}}, \mathcal{F})}) T^n \end{aligned}$$

by the same formula again. Now, comparing powers of T and using the Mobius inversion formula, we see that Theorem 44.98.2 is a consequence of the following equality

$$\sum_{d|n} d \sum_{\substack{x \in |X| \\ \deg x = d}} \text{Tr}((\pi_X^{n/d})^* |_{\mathcal{F}_{\bar{x}}}) = \sum_i (-1)^i \text{Tr}((\pi_X^n)^* |_{H_c^i(X_{\bar{k}}, \mathcal{F})}).$$

Writing k_n for the degree n extension of k , $X_n = X \times_{\text{Spec } k} \text{Spec}(k_n)$ and ${}_n\mathcal{F} = \mathcal{F}|_{X_n}$, this boils down to

$$\sum_{x \in X_n(k_n)} \text{Tr}(\pi_X^* |_{{}_n\mathcal{F}_{\bar{x}}}) = \sum_i (-1)^i \text{Tr}((\pi_X^n)^* |_{H_c^i((X_n)_{\bar{k}}, {}_n\mathcal{F})})$$

which is a consequence of Theorem 44.98.5.

Theorem 44.98.4. *Let X/k be as above, let Λ be a finite ring with $\#\Lambda \in k^*$ and $K \in D_{ctf}(X, \Lambda)$. Then $R\Gamma_c(X_{\bar{k}}, K) \in D_{perf}(\Lambda)$ and*

$$\sum_{x \in X(k)} \text{Tr}(\pi_x |_{K_{\bar{x}}}) = \text{Tr}(\pi_X^* |_{R\Gamma_c(X_{\bar{k}}, K)}).$$

Proof. Note that we have already proved this (REFERENCE) when $\dim X \leq 1$. The general case follows easily from that case together with the proper base change theorem. \square

Theorem 44.98.5. *Let X be a separated scheme of finite type over a finite field k and \mathcal{F} be a \mathbf{Q}_ℓ -sheaf on X . Then $\dim_{\mathbf{Q}_\ell} H_c^i(X_{\bar{k}}, \mathcal{F})$ is finite for all i , and is nonzero for $0 \leq i \leq 2 \dim X$ only. Furthermore, we have*

$$\sum_{x \in X(k)} \text{Tr}(\pi_x |_{\mathcal{F}_{\bar{x}}}) = \sum_i (-1)^i \text{Tr}(\pi_X^* |_{H_c^i(X_{\bar{k}}, \mathcal{F})}).$$

Proof. We explain how to deduce this from Theorem 44.98.4. We first use some étale cohomology arguments to reduce the proof to an algebraic statement which we subsequently prove.

Let \mathcal{F} be as in the theorem. We can write \mathcal{F} as $\mathcal{F}' \otimes \mathbf{Q}_\ell$ where $\mathcal{F}' = \{\mathcal{F}'_n\}$ is a \mathbf{Z}_ℓ -sheaf without torsion, i.e., $\ell : \mathcal{F}' \rightarrow \mathcal{F}'$ has trivial kernel in the category of \mathbf{Z}_ℓ -sheaves. Then each \mathcal{F}'_n is a flat constructible $\mathbf{Z}/\ell^n\mathbf{Z}$ -module on $X_{\text{étale}}$, so $\mathcal{F}'_n \in D_{\text{ctf}}(X, \mathbf{Z}/\ell^n\mathbf{Z})$ and $\mathcal{F}'_{n+1} \otimes_{\mathbf{Z}/\ell^{n+1}\mathbf{Z}}^{\mathbf{L}} \mathbf{Z}/\ell^n\mathbf{Z} = \mathcal{F}'_n$. Note that the last equality holds also for standard (non-derived) tensor product, since \mathcal{F}'_n is flat (it is the same equality). Therefore,

- (1) the complex $K_n = R\Gamma_c(X_{\bar{k}}, \mathcal{F}'_n)$ is perfect, and it is endowed with an endomorphism $\pi_n : K_n \rightarrow K_n$ in $D(\mathbf{Z}/\ell^n\mathbf{Z})$,
- (2) there are identifications

$$K_{n+1} \otimes_{\mathbf{Z}/\ell^{n+1}\mathbf{Z}}^{\mathbf{L}} \mathbf{Z}/\ell^n\mathbf{Z} = K_n$$

in $D_{\text{per f}}(\mathbf{Z}/\ell^n\mathbf{Z})$, compatible with the endomorphisms π_{n+1} and π_n (see [Del77, Rapport 4.12]),

- (3) the equality $\text{Tr}(\pi_X^*|_{K_n}) = \sum_{x \in X(k)} \text{Tr}(\pi_x|_{(\mathcal{F}'_n)_{\bar{x}}})$ holds, and
- (4) for each $x \in X(k)$, the elements $\text{Tr}(\pi_x|_{(\mathcal{F}'_n)_{\bar{x}}}) \in \mathbf{Z}/\ell^n\mathbf{Z}$ form an element of \mathbf{Z}_ℓ which is equal to $\text{Tr}(\pi_x|_{\mathcal{F}_{\bar{x}}}) \in \mathbf{Q}_\ell$.

It thus suffices to prove the following algebra lemma. □

Lemma 44.98.6. *Suppose we have $K_n \in D_{\text{per f}}(\mathbf{Z}/\ell^n\mathbf{Z})$, $\pi_n : K_n \rightarrow K_n$ and isomorphisms $\varphi_n : K_{n+1} \otimes_{\mathbf{Z}/\ell^{n+1}\mathbf{Z}}^{\mathbf{L}} \mathbf{Z}/\ell^n\mathbf{Z} \rightarrow K_n$ compatible with π_{n+1} and π_n . Then*

- (1) the elements $t_n = \text{Tr}(\pi_n|_{K_n}) \in \mathbf{Z}/\ell^n\mathbf{Z}$ form an element $t_\infty = \{t_n\}$ of \mathbf{Z}_ℓ ,
- (2) the \mathbf{Z}_ℓ -module $H_\infty^i = \lim_n H^i(k_n)$ is finite and is nonzero for finitely many i only, and
- (3) the operators $H^i(\pi_n) : H^i(K_n) \rightarrow H^i(K_n)$ are compatible and define $\pi_\infty^i : H_\infty^i \rightarrow H_\infty^i$ satisfying

$$\sum (-1)^i \text{Tr}(\pi_\infty^i|_{H_\infty^i \otimes_{\mathbf{Z}_\ell} \mathbf{Q}_\ell}) = t_\infty.$$

Proof. Since $\mathbf{Z}/\ell^n\mathbf{Z}$ is a local ring and K_n is perfect, each K_n can be represented by a finite complex K_n^\bullet of finite free $\mathbf{Z}/\ell^n\mathbf{Z}$ -modules such that the map $K_n^p \rightarrow K_n^{p+1}$ has image contained in ℓK_n^{p+1} . It is a fact that such a complex is unique up to isomorphism. Moreover π_n can be represented by a morphism of complexes $\pi_n^\bullet : K_n^\bullet \rightarrow K_n^\bullet$ (which is unique up to homotopy). By the same token the isomorphism $\varphi_n : K_{n+1} \otimes_{\mathbf{Z}/\ell^{n+1}\mathbf{Z}}^{\mathbf{L}} \mathbf{Z}/\ell^n\mathbf{Z} \rightarrow K_n$ is represented by a map of complexes

$$\varphi_n^\bullet : K_{n+1}^\bullet \otimes_{\mathbf{Z}/\ell^{n+1}\mathbf{Z}} \mathbf{Z}/\ell^n\mathbf{Z} \rightarrow K_n^\bullet.$$

In fact, φ_n^\bullet is an isomorphism of complexes, thus we see that

- there exist $a, b \in \mathbf{Z}$ independent of n such that $K_n^i = 0$ for all $i \notin [a, b]$, and
- the rank of K_n^i is independent of n .

Therefore, the module $K_\infty^i = \lim_n \{K_n^i, \varphi_n^i\}$ is a finite free \mathbf{Z}_ℓ -module and K_∞^\bullet is a finite complex of finite free \mathbf{Z}_ℓ -modules. By induction on the number of nonzero terms, one can prove that $H^i(K_\infty^\bullet) = \lim_n H^i(K_n^\bullet)$ (this is not true for unbounded complexes). We conclude that $H_\infty^i = H^i(K_\infty^\bullet)$ is a finite \mathbf{Z}_ℓ -module. This proves

ii. To prove the remainder of the lemma, we need to overcome the possible non-commutativity of the diagrams

$$\begin{array}{ccc}
 K_{n+1}^\bullet & \xrightarrow{\varphi_n^\bullet} & K_n^\bullet \\
 \pi_{n+1}^\bullet \downarrow & & \downarrow \pi_n^\bullet \\
 K_{n+1}^\bullet & \xrightarrow{\varphi_n^\bullet} & K_n^\bullet
 \end{array}$$

However, this diagram does commute in the derived category, hence it commutes up to homotopy. We inductively replace π_n^\bullet for $n \geq 2$ by homotopic maps of complexes making these diagrams commute. Namely, if $h^i : K_{n+1}^i \rightarrow K_n^{i-1}$ is a homotopy, i.e.,

$$\pi_n^\bullet \circ \varphi_n^\bullet - \varphi_n^\bullet \circ \pi_{n+1}^\bullet = dh + hd,$$

then we choose $\tilde{h}^i : K_{n+1}^i \rightarrow K_{n+1}^{i-1}$ lifting h^i . This is possible because K_{n+1}^i free and $K_{n+1}^{i-1} \rightarrow K_n^{i-1}$ is surjective. Then replace π_n^\bullet by $\tilde{\pi}_n^\bullet$ defined by

$$\tilde{\pi}_{n+1}^\bullet = \pi_{n+1}^\bullet + d\tilde{h} + \tilde{h}d.$$

With this choice of $\{\pi_n^\bullet\}$, the above diagrams commute, and the maps fit together to define an endomorphism $\pi_\infty^\bullet = \lim_n \pi_n^\bullet$ of K_∞^\bullet . Then part *i* is clear: the elements $t_n = \sum (-1)^i \text{Tr}(\pi_n^i|_{K_n^i})$ fit into an element t_∞ of \mathbf{Z}_ℓ . Moreover

$$\begin{aligned}
 t_\infty &= \sum (-1)^i \text{Tr}_{\mathbf{Z}_\ell}(\pi_\infty^i|_{K_\infty^i}) \\
 &= \sum (-1)^i \text{Tr}_{\mathbf{Q}_\ell}(\pi_\infty^i|_{K_\infty^i \otimes_{\mathbf{Z}_\ell} \mathbf{Q}_\ell}) \\
 &= \sum (-1)^i \text{Tr}(\pi_\infty|_{H^i(K_\infty^\bullet \otimes \mathbf{Q}_\ell)})
 \end{aligned}$$

where the last equality follows from the fact that \mathbf{Q}_ℓ is a field, so the complex $K_\infty^\bullet \otimes \mathbf{Q}_\ell$ is quasi-isomorphic to its cohomology $H^i(K_\infty^\bullet \otimes \mathbf{Q}_\ell)$. The latter is also equal to $H^i(K_\infty^\bullet) \otimes_{\mathbf{Z}} \mathbf{Q}_\ell = H_\infty^i \otimes \mathbf{Q}_\ell$, which finishes the proof of the lemma, and also that of Theorem 44.98.5. \square

44.99. List of things which we should add above

What did we skip the proof of in the lectures so far:

- (1) curves and their Jacobians,
- (2) proper base change theorem,
- (3) inadequate discussion of $R\Gamma_c$,
- (4) more generally, given $f : X \rightarrow S$ finite type, separated S quasi-projective, discussion of $Rf_!$ on étale sheaves.
- (5) discussion of $\otimes^{\mathbf{L}}$
- (6) discussion of why $R\Gamma_c$ commutes with $\otimes^{\mathbf{L}}$

44.100. Examples of L-functions

We use Theorem 44.98.2 for curves to give examples of L -functions

44.101. Constant sheaves

Let k be a finite field, X a smooth, geometrically irreducible curve over k and $\mathcal{F} = \underline{\mathbf{Q}}_\ell$ the constant sheaf. If \bar{x} is a geometric point of X , the Galois module $\mathcal{F}_{\bar{x}} = \underline{\mathbf{Q}}_\ell$ is trivial, so

$$\det(1 - \pi_x^* T^{\deg x}|_{\mathcal{F}_{\bar{x}}})^{-1} = \frac{1}{1 - T^{\deg x}}.$$

Applying Theorem 44.98.2, we get

$$\begin{aligned} L(X, \mathcal{F}) &= \prod_{i=0}^2 \det(1 - \pi_X^* T|_{H_c^i(X_{\bar{k}}, \mathbf{Q}_\ell)})^{(-1)^{i+1}} \\ &= \frac{\det(1 - \pi_X^* T|_{H_c^1(X_{\bar{k}}, \mathbf{Q}_\ell)})}{\det(1 - \pi_X^* T|_{H_c^0(X_{\bar{k}}, \mathbf{Q}_\ell)}) \cdot \det(1 - \pi_X^* T|_{H_c^2(X_{\bar{k}}, \mathbf{Q}_\ell))}. \end{aligned}$$

To compute the latter, we distinguish two cases.

Projective case. Assume that X is projective, so $H_c^i(X_{\bar{k}}, \mathbf{Q}_\ell) = H^i(X_{\bar{k}}, \mathbf{Q}_\ell)$, and we have

$$H^i(X_{\bar{k}}, \mathbf{Q}_\ell) = \begin{cases} \mathbf{Q}_\ell & \pi_X^* = 1 & \text{if } i = 0, \\ \mathbf{Q}_\ell^{2g} & \pi_X^* = ? & \text{if } i = 1, \\ \mathbf{Q}_\ell & \pi_X^* = q & \text{if } i = 2. \end{cases}$$

The identification of the action of π_X^* on H^2 comes from Lemma 44.66.4 and the fact that the degree of π_X is $q = \#(k)$. We do not know much about the action of π_X^* on the degree 1 cohomology. Let us call $\alpha_1, \dots, \alpha_{2g}$ its eigenvalues in $\underline{\mathbf{Q}}_\ell$. Putting everything together, Theorem 44.98.2 yields the equality

$$\prod_{x \in |X|} \frac{1}{1 - T^{\deg x}} = \frac{\det(1 - \pi_X^* T|_{H^1(X_{\bar{k}}, \mathbf{Q}_\ell)})}{(1 - T)(1 - qT)} = \frac{(1 - \alpha_1 T) \dots (1 - \alpha_{2g} T)}{(1 - T)(1 - qT)}$$

from which we deduce the following result.

Lemma 44.101.1. *Let X be a smooth, projective, geometrically irreducible curve over a finite field k . Then*

- (1) *the L -function $L(X, \mathbf{Q}_\ell)$ is a rational function,*
- (2) *the eigenvalues $\alpha_1, \dots, \alpha_{2g}$ of π_X^* on $H^1(X_{\bar{k}}, \mathbf{Q}_\ell)$ are algebraic integers independent of ℓ ,*
- (3) *the number of rational points of X on k_n , where $[k_n : k] = n$, is*

$$\#X(k_n) = 1 - \sum_{i=1}^{2g} \alpha_i^n + q^n,$$

- (4) *for each i , $|\alpha_i| < q$.*

Proof. Part (3) is Theorem 44.98.5 applied to $\mathcal{F} = \underline{\mathbf{Q}}_\ell$ on $X \otimes k_n$. For part (4), use the following result. □

Exercise 44.101.2. Let $\alpha_1, \dots, \alpha_n \in \mathbf{C}$. Then for any conic sector containing the positive real axis of the form $C_\varepsilon = \{z \in \mathbf{C} \mid |\arg z| < \varepsilon\}$ with $\varepsilon > 0$, there exists an integer $k \geq 1$ such that $\alpha_1^k, \dots, \alpha_n^k \in C_\varepsilon$.

Then prove that $|\alpha_i| \leq q$ for all i . Then, use elementary considerations on complex numbers to prove (as in the proof of the prime number theorem) that $|\alpha_i| < q$. In fact, the Riemann hypothesis says that for all $|\alpha_i| = \sqrt{q}$ for all i . We will come back to this later.

Affine case. Assume now that X is affine, say $X = \bar{X} - \{x_1, \dots, x_n\}$ where $j : X \hookrightarrow \bar{X}$ is a projective nonsingular completion. Then $H_c^0(\bar{X}_{\bar{k}}, \mathbf{Q}_\ell) = 0$ and $H_c^2(X_{\bar{k}}, \mathbf{Q}_\ell) = H^2(\bar{X}_{\bar{k}}, \mathbf{Q}_\ell)$ so Theorem 44.98.2 reads

$$L(X, \mathbf{Q}_\ell) = \prod_{x \in |X|} \frac{1}{1 - T^{\deg x}} = \frac{\det(1 - \pi_X^* T |_{H_c^1(X_{\bar{k}}, \mathbf{Q}_\ell)})}{1 - qT}.$$

On the other hand, the previous case gives

$$\begin{aligned} L(X, \mathbf{Q}_\ell) &= L(\bar{X}, \mathbf{Q}_\ell) \prod_{i=1}^n (1 - T^{\deg x_i}) \\ &= \frac{\prod_{i=1}^n (1 - T^{\deg x_i}) \prod_{j=1}^{2g} (1 - \alpha_j T)}{(1 - T)(1 - qT)}. \end{aligned}$$

Therefore, we see that $\dim H_c^1(X_{\bar{k}}, \mathbf{Q}_\ell) = 2g + \sum_{i=1}^n \deg(x_i) - 1$, and the eigenvalues $\alpha_1, \dots, \alpha_{2g}$ of $\pi_{\bar{X}}^*$ acting on the degree 1 cohomology are roots of unity. More precisely, each x_i gives a complete set of $\deg(x_i)$ th roots of unity, and one occurrence of 1 is omitted. To see this directly using coherent sheaves, consider the short exact sequence on \bar{X}

$$0 \rightarrow j_! \mathbf{Q}_\ell \rightarrow \mathbf{Q}_\ell \rightarrow \bigoplus_{i=1}^n \mathbf{Q}_{\ell, x_i} \rightarrow 0.$$

The long exact cohomology sequence reads

$$0 \rightarrow \mathbf{Q}_\ell \rightarrow \bigoplus_{i=1}^n \mathbf{Q}_\ell^{\oplus \deg x_i} \rightarrow H_c^1(X_{\bar{k}}, \mathbf{Q}_\ell) \rightarrow H_c^1(\bar{X}_{\bar{k}}, \mathbf{Q}_\ell) \rightarrow 0$$

where the action of Frobenius on $\bigoplus_{i=1}^n \mathbf{Q}_\ell^{\oplus \deg x_i}$ is by cyclic permutation of each term; and $H_c^2(X_{\bar{k}}, \mathbf{Q}_\ell) = H^2(\bar{X}_{\bar{k}}, \mathbf{Q}_\ell)$.

44.102. The Legendre family

Let k be a finite field of odd characteristic, $X = \text{Spec}(k[\lambda, \frac{1}{\lambda(\lambda-1)}])$, and consider the family of elliptic curves $f : E \rightarrow X$ on \mathbf{P}_X^2 whose affine equation is $y^2 = x(x-1)(x-\lambda)$. We set $\mathcal{F} = Rf_* \mathbf{Q}_\ell = \{R^1 f_* \mathbf{Z}/\ell^n \mathbf{Z}\}_{n \geq 1} \otimes \mathbf{Q}_\ell$. In this situation, the following is true

- for each $n \geq 1$, the sheaf $R^1 f_* (\mathbf{Z}/\ell^n \mathbf{Z})$ is finite locally constant – in fact, it is free of rank 2 over $\mathbf{Z}/\ell^n \mathbf{Z}$,
- the system $\{R^1 f_* \mathbf{Z}/\ell^n \mathbf{Z}\}_{n \geq 1}$ is a lisse ℓ -adic sheaf, and
- for all $x \in |X|$, $\det(1 - \pi_x T^{\deg x} |_{\mathcal{F}_{\bar{x}}}) = (1 - \alpha_x T^{\deg x})(1 - \beta_x T^{\deg x})$ where α_x, β_x are the eigenvalues of the geometric frobenius of E_x acting on $H^1(E_{\bar{x}}, \mathbf{Q}_\ell)$.

Note that E_x is only defined over $\kappa(x)$ and not over k . The proof of these facts uses the proper base change theorem and the local acyclicity of smooth morphisms. For details, see [Del77]. It follows that

$$L(E/X) := L(X, \mathcal{F}) = \prod_{x \in |X|} \frac{1}{(1 - \alpha_x T^{\deg x})(1 - \beta_x T^{\deg x})}.$$

Applying Theorem 44.98.2 we get

$$L(E/X) = \prod_{i=0}^2 \det(1 - \pi_X^* T|_{H_c^i(X_{\bar{k}}, \mathcal{F})})^{(-1)^{i+1}},$$

and we see in particular that this is a rational function. Furthermore, it is relatively easy to show that $H_c^0(X_{\bar{k}}, \mathcal{F}) = H_c^2(X_{\bar{k}}, \mathcal{F}) = 0$, so we merely have

$$L(E/X) = \det(1 - \pi_X^* T|_{H_c^1(X, \mathcal{F})}).$$

To compute this determinant explicitly, consider the Leray spectral sequence for the proper morphism $f : E \rightarrow X$ over \mathbf{Q}_ℓ , namely

$$H_c^i(X_{\bar{k}}, R^j f_* \mathbf{Q}_\ell) \Rightarrow H_c^{i+j}(E_{\bar{k}}, \mathbf{Q}_\ell)$$

which degenerates. We have $f_* \mathbf{Q}_\ell = \mathbf{Q}_\ell$ and $R^1 f_* \mathbf{Q}_\ell = \mathcal{F}$. The sheaf $R^2 f_* \mathbf{Q}_\ell = \mathbf{Q}_\ell(-1)$ is the *Tate twist* of \mathbf{Q}_ℓ , i.e., it is the sheaf \mathbf{Q}_ℓ where the Galois action is given by multiplication by $\#\kappa(x)$ on the stalk at \bar{x} . It follows that, for all $n \geq 1$,

$$\begin{aligned} \#E(k_n) &= \sum_i (-1)^i \text{Tr}(\pi_E^n |_{H_c^i(E_{\bar{k}}, \mathbf{Q}_\ell)}) \\ &= \sum_{i,j} (-1)^{i+j} \text{Tr}(\pi_X^n |_{H_c^i(X_{\bar{k}}, R^j f_* \mathbf{Q}_\ell)}) \\ &= (q^n - 2) + \text{Tr}(\pi_X^n |_{H_c^1(X_{\bar{k}}, \mathcal{F})}) + q^n(q^n - 2) \\ &= q^{2n} - q^n - 2 + \text{Tr}(\pi_X^n |_{H_c^1(X_{\bar{k}}, \mathcal{F})}) \end{aligned}$$

where the first equality follows from Theorem 44.98.5, the second one from the Leray spectral sequence and the third one by writing down the higher direct images of \mathbf{Q}_ℓ under f . Alternatively, we could write

$$\#E(k_n) = \sum_{x \in X(k_n)} \#E_x(k_n)$$

and use the trace formula for each curve. We can also find the number of k_n -rational points simply by counting. The zero section contributes $q^n - 2$ points (we omit the points where $\lambda = 0, 1$) hence

$$\#E(k_n) = q^n - 2 + \#\{y^2 = x(x-1)(x-\lambda), \lambda \neq 0, 1\}.$$

Now we have

$$\begin{aligned} &\#\{y^2 = x(x-1)(x-\lambda), \lambda \neq 0, 1\} \\ &= \#\{y^2 = x(x-1)(x-\lambda) \text{ in } \mathbf{A}^3\} - \#\{y^2 = x^2(x-1)\} - \#\{y^2 = x(x-1)^2\} \\ &= \#\{\lambda = \frac{-y^2}{x(x-1)} + x, x \neq 0, 1\} + \#\{y^2 = x(x-1)(x-\lambda), x = 0, 1\} - 2(q^n - \varepsilon_n) \\ &= q^n(q^n - 2) + 2q^n - 2(q^n - \varepsilon_n) \\ &= q^{2n} - 2q^n + 2\varepsilon_n \end{aligned}$$

where $\varepsilon_n = 1$ if -1 is a square in k_n , 0 otherwise, i.e.,

$$\varepsilon_n = \frac{1}{2} \left(1 + \left(\frac{-1}{k_n} \right) \right) = \frac{1}{2} \left(1 + (-1)^{\frac{q^n-1}{2}} \right).$$

Thus $\#E(k_n) = q^{2n} - q^n - 2 + 2\varepsilon_n$. Comparing with the previous formula, we find

$$\text{Tr}(\pi_X^n |_{H_c^1(X_{\bar{k}}, \mathcal{F})}) = 2\varepsilon_n = 1 + (-1)^{\frac{q^n-1}{2}},$$

which implies, by elementary algebra of complex numbers, that if -1 is a square in k_n^* , then $\dim H_c^1(X_{\bar{k}}, \mathcal{F}) = 2$ and the eigenvalues are 1 and 1. Therefore, in that case we have

$$L(E/X) = (1 - T)^2.$$

44.103. Exponential sums

A standard problem in number theory is to evaluate sums of the form

$$S_{a,b}(p) = \sum_{x \in \mathbf{F}_p - \{0,1\}} e^{\frac{2\pi i x^a (x-1)^b}{p}}.$$

In our context, this can be interpreted as a cohomological sum as follows. Consider the base scheme $S = \text{Spec}(\mathbf{F}_p[x, \frac{1}{x(x-1)}])$ and the affine curve $f : X \rightarrow \mathbf{P}^1 - \{0, 1, \infty\}$ over S given by the equation $y^{p-1} = x^a(x-1)^b$. This is a finite étale Galois cover with group \mathbf{F}_p^* and there is a splitting

$$f_*(\bar{\mathbf{Q}}_\ell^*) = \bigoplus_{\chi: \mathbf{F}_p^* \rightarrow \bar{\mathbf{Q}}_\ell^*} \mathcal{F}_\chi$$

where χ varies over the characters of \mathbf{F}_p^* and \mathcal{F}_χ is a rank 1 lisse $\bar{\mathbf{Q}}_\ell$ -sheaf on which \mathbf{F}_p^* acts via χ on stalks. We get a corresponding decomposition

$$H_c^1(X_{\bar{k}}, \bar{\mathbf{Q}}_\ell) = \bigoplus_{\chi} H^1(\mathbf{P}_{\bar{k}}^1 - \{0, 1, \infty\}, \mathcal{F}_\chi)$$

and the cohomological interpretation of the exponential sum is given by the trace formula applied to \mathcal{F}_χ over $\mathbf{P}^1 - \{0, 1, \infty\}$ for some suitable χ . It reads

$$S_{a,b}(p) = -\text{Tr}(\pi_X^* |_{H^1(\mathbf{P}_{\bar{k}}^1 - \{0,1,\infty\}, \mathcal{F}_\chi)}).$$

The general yoga of Weil suggests that there should be some cancellation in the sum. Applying (roughly) the Riemann-Hurwitz formula, we see that

$$2g_X - 2 \approx -2(p-1) + 3(p-2) \approx p$$

so $g_X \approx p/2$, which also suggests that the χ -pieces are small.

44.104. Trace formula in terms of fundamental groups

In the following sections we reformulate the trace formula completely in terms of the fundamental group of a curve, except if the curve happens to be \mathbf{P}^1 .

44.105. Fundamental groups

X connected scheme $\bar{x} \rightarrow X$ geometric point consider the functor

$$F_{\bar{x}} : \begin{array}{ccc} \text{finite étale} & \longrightarrow & \text{finite sets} \\ \text{schemes over } X & & \\ Y/X & \longmapsto & F_{\bar{x}}(Y) = \left\{ \begin{array}{l} \text{geom points } \bar{y} \\ \text{of } Y \text{ lying over } \bar{x} \end{array} \right\} = Y_{\bar{x}} \end{array}$$

Set

$$\pi_1(X, \bar{x}) = \text{Aut}(F_{\bar{x}}) = \text{set of automorphisms of the functor } F_{\bar{x}}$$

Note that for every finite étale $Y \rightarrow X$ there is an action

$$\pi_1(X, \bar{x}) \times F_{\bar{x}}(Y) \rightarrow F_{\bar{x}}(Y)$$

Definition 44.105.1. A subgroup of the form $\text{Stab}(\bar{y} \in F_{\bar{x}}(Y)) \subset \pi_1(X, \bar{x})$ is called *open*.

Theorem 44.105.2 (Grothendieck). *Let X be a connected scheme.*

- (1) *There is a topology on $\pi_1(X, \bar{x})$ such that the open subgroups form a fundamental system of open nbhds of $e \in \pi_1(X, \bar{x})$.*
- (2) *With topology of (1) the group $\pi_1(X, \bar{x})$ is a profinite group.*
- (3) *The functor*

$$\begin{array}{ccc} \begin{array}{c} \text{schemes finite} \\ \text{étale over } X \end{array} & \rightarrow & \begin{array}{c} \text{finite discrete continuous} \\ \pi_1(X, \bar{x})\text{-sets} \end{array} \\ Y/X & \mapsto & F_{\bar{x}}(Y) \text{ with its natural action} \end{array}$$

is an equivalence of categories.

Proof. See [Gro71]. □

Proposition 44.105.3. *Let X be an integral normal Noetherian scheme. Let $\bar{y} \rightarrow X$ be an algebraic geometric point lying over the generic point $\eta \in X$. Then*

$$\pi_x(X, \bar{\eta}) = \text{Gal}(M/\kappa(\eta))$$

($\kappa(\eta)$, function field of X) where

$$\kappa(\bar{\eta}) \supset M \supset \kappa(\eta) = k(X)$$

is the max sub-extension such that for every finite sub extension $M \supset L \supset \kappa(\eta)$ the normalization of X in L is finite étale over X .

Proof. Omitted. □

Change of base point. For any \bar{x}_1, \bar{x}_2 geom. points of X there exists an isom. of fibre functions

$$\mathcal{F}_{\bar{x}_1} \cong \mathcal{F}_{\bar{x}_2}$$

(This is a path from \bar{x}_1 to \bar{x}_2 .) Conjugation by this path gives isom

$$\pi_1(X, \bar{x}_1) \cong \pi_1(X, \bar{x}_2)$$

well defined up to inner actions.

Functoriality. For any morphism $X_1 \rightarrow X_2$ of connected schemes any $\bar{x} \in X_1$ there is a canonical map

$$\pi_1(X_1, \bar{x}) \rightarrow \pi_1(X_2, \bar{x})$$

(Why? because the fibre functor ...)

Base field. Let X be a variety over a field k . Then we get

$$\pi_1(X, \bar{x}) \rightarrow \pi_1(\text{Spec}(k), \bar{x}) =^{\text{prop}} \text{Gal}(k^{\text{sep}}/k)$$

This map is surjective if and only if X is geometrically connected over k . So in the geometrically connected case we get s.e.s. of profinite groups

$$1 \rightarrow \pi_1(X_{\bar{k}}, \bar{x}) \rightarrow \pi_1(X, \bar{x}) \rightarrow \text{Gal}(k^{\text{sep}}/k) \rightarrow 1$$

($\pi_1(X_{\bar{k}}, \bar{x})$: geometric fundamental group of X , $\pi_1(X, \bar{x})$: arithmetic fundamental group of X)

Comparison. If X is a variety over \mathbf{C} then

$$\pi_1(X, \bar{x}) = \text{profinite completion of } \pi_1(X(\mathbf{C}))(\text{usual topology}), x$$

(have $x \in X(\mathbf{C})$)

Frobenii. X variety over k , $\#k < \infty$. For any $x \in X$ closed point, let

$$F_x \in \pi_1(x, \bar{x}) = \text{Gal}(\kappa(x)^{\text{sep}}/\kappa(x))$$

be the geometric frobenius. Let $\bar{\eta}$ be an alg. geom. gen. pt. Then

$$\pi_1(X, \bar{\eta}) \xleftarrow{\cong} \pi_1(X, \bar{x}) \xleftarrow{\text{functoriality}} \pi_1(x, \bar{x})$$

Easy fact:

$$\begin{array}{ccc} \pi_1(X, \bar{\eta}) & \xrightarrow{\text{deg}} \pi_1(\text{Spec}(k), \bar{\eta})^* & = \text{Gal}(k^{\text{sep}}/k) \\ & & \parallel \\ F_x & \mapsto & \widehat{\mathbf{Z}} \cdot F_{\text{Spec}(k)} \\ & & \text{deg}(x) \cdot F_{\text{Spec}(k)} \end{array}$$

Recall: $\text{deg}(x) = [\kappa(x) : k]$

Fundamental groups and lisse sheaves. Let X be a connected scheme, \bar{x} geom. pt. There are equivalences of categories

$$\begin{array}{ccc} (\Lambda \text{ finite ring}) & \begin{array}{c} \text{fin. loc. const. sheaves of} \\ \Lambda\text{-modules of } X_{\acute{e}t\text{ale}} \end{array} & \leftrightarrow \begin{array}{c} \text{finite (discrete) } \Lambda\text{-modules} \\ \text{with continuous } \pi_1(X, \bar{x})\text{-action} \end{array} \\ (\ell \text{ a prime}) & \begin{array}{c} \text{lisse } \ell\text{-adic} \\ \text{sheaves} \end{array} & \leftrightarrow \begin{array}{c} \text{finitely generated } \mathbf{Z}_\ell\text{-modules } M \text{ with continuous} \\ \pi_1(X, \bar{x})\text{-action where we use } \ell\text{-adic topology on } M \end{array} \end{array}$$

In particular lisse \mathbf{Q}_ℓ -sheaves correspond to continuous homomorphisms

$$\pi_1(X, \bar{x}) \rightarrow \text{GL}_r(\mathbf{Q}_\ell), \quad r \geq 0$$

Notation: A module with action (M, ρ) corresponds to the sheaf \mathcal{F}_ρ .

Trace formulas. X variety over k , $\#k < \infty$.

- (1) Λ finite ring ($\#\Lambda, \#k = 1$)

$$\rho : \pi_1(X, \bar{x}) \rightarrow \text{GL}_r(\Lambda)$$

continuous. For every $n \geq 1$ we have

$$\sum_{d|n} d \left(\sum_{\substack{x \in |X| \\ \text{deg}(x)=d}} \text{Tr}(\rho(F_x^{n/d})) \right) = \text{Tr}((\pi_x^n)^* |_{R\Gamma_c(X_{\bar{k}}, \mathcal{F}_\rho)})$$

- (2) $l \neq \text{char}(k)$ prime, $\rho : \pi_1(X, \bar{x}) \rightarrow \text{GL}_r(\mathbf{Q}_l)$. For any $n \geq 1$

$$\sum_{d|n} d \left(\sum_{\substack{x \in |X| \\ \text{deg}(x)=d}} \text{Tr}(\rho(F_x^{n/d})) \right) = \sum_{i=0}^{2 \dim X} (-1)^i \text{Tr}(\pi_X^* |_{H_c^i(X_{\bar{k}}, \mathcal{F}_\rho)})$$

Weil conjectures. (Deligne-Weil I, 1974) X smooth proj. over k , $\#k = q$, then the eigenvalues of π_X^* on $H^i(X_{\bar{k}}, \mathbf{Q}_l)$ are algebraic integers α with $|\alpha| = q^{1/2}$.

Deligne's conjectures. (almost completely proved by Lafforgue + ...) Let X be a normal variety over k finite

$$\rho : \pi_1(X, \bar{x}) \longrightarrow \text{GL}_r(\mathbf{Q}_l)$$

continuous. Assume: ρ irreducible $\det(\rho)$ of finite order. Then

- (1) there exists a number field E such that for all $x \in |X|$ (closed points) the char. poly of $\rho(F_x)$ has coefficients in E .
- (2) for any $x \in |X|$ the eigenvalues $\alpha_{x,i}$, $i = 1, \dots, r$ of $\rho(F_x)$ have complex absolute value 1. (these are algebraic numbers not necessary integers)

- (3) for every finite place λ (not dividing p), of E (maybe after enlarging E a bit) there exists

$$\rho\lambda : \pi_1(X, \bar{x}) \rightarrow \mathrm{GL}_r(E_\lambda)$$

compatible with ρ . (some char. polys of F_x 's)

Theorem 44.105.4 (Deligne, Weil II). *For a sheaf \mathcal{F}_ρ with ρ satisfying the conclusions of the conjecture above then the eigenvalues of π_X^* on $H_c^i(X_{\bar{k}}, \mathcal{F}_\rho)$ are algebraic numbers α with absolute values*

$$|\alpha| = q^{w/2}, \text{ for } w \in \mathbf{Z}, w \leq i$$

Moreover, if X smooth and proj. then $w = i$.

Proof. See [Del74a]. □

44.106. Profinite groups, cohomology and homology

Let G be a profinite group.

Cohomology. Consider the category of discrete modules with continuous G -action. This category has enough injectives and we can define

$$H^i(G, M) = R^i H^0(G, M) = R^i(M \mapsto M^G)$$

Also there is a derived version $RH^0(G, -)$.

Homology. Consider the category of compact abelian groups with continuous G -action. This category has enough projectives and we can define

$$H_i(G, M) = L_i H_0(G, M) = L_i(M \mapsto M_G)$$

and there is also a derived version.

Trivial duality. The functor $M \mapsto M^\wedge = \mathrm{Hom}_{cont}(M, S^1)$ exchanges the categories above and

$$H^i(G, M)^\wedge = H_i(G, M^\wedge)$$

Moreover, this functor maps torsion discrete G -modules to profinite continuous G -modules and vice versa, and if M is either a discrete or profinite continuous G -module, then $M^\wedge = \mathrm{Hom}(M, \mathbf{Q}/\mathbf{Z})$.

Notes on Homology.

- (1) If we look at Λ -modules for a finite ring Λ then we can identify

$$H_i(G, M) = \mathrm{Tor}_i^{\Lambda[[G]]}(M, \Lambda)$$

where $\Lambda[[G]]$ is the limit of the group algebras of the finite quotients of G .

- (2) If G is a normal subgroup of Γ , and Γ is also profinite then
- $H^0(G, -)$: discrete Γ -module \rightarrow discrete Γ/G -modules
 - $H_0(G, -)$: compact Γ -modules \rightarrow compact Γ/G -modules
- and hence the profinite group Γ/G acts on the cohomology groups of G with values in a Γ -module. In other words, there are derived functors

$$RH^0(G, -) : D^+(\text{discrete } \Gamma\text{-modules}) \longrightarrow D^+(\text{discrete } \Gamma/G\text{-modules})$$

and similarly for $LH_0(G, -)$.

44.107. Cohomology of curves, revisited

Let k be a field, X be geometrically connected, smooth curve over k . We have the fundamental short exact sequence

$$1 \rightarrow \pi_1(X_{\bar{k}}, \bar{\eta}) \rightarrow \pi_1(X, \bar{\eta}) \rightarrow \text{Gal}(k^{sep}/k) \rightarrow 1$$

If Λ is a finite ring with $\#\Lambda \in k^*$ and M a finite Λ -module, and we are given

$$\rho : \pi_1(X, \bar{\eta}) \rightarrow \text{Aut}_\Lambda(M)$$

continuous, then \mathcal{F}_ρ denotes the associated sheaf on $X_{\acute{e}tale}$.

Lemma 44.107.1. *There is a canonical isomorphism*

$$H_c^2(X_{\bar{k}}, \mathcal{F}_\rho) = (M)_{\pi_1(X_{\bar{k}}, \bar{\eta})}(-1)$$

as $\text{Gal}(k^{sep}/k)$ -modules.

Here the subscript $\pi_1(X_{\bar{k}}, \bar{\eta})$ indicates co-invariants, and (-1) indicates the Tate twist i.e., $\sigma \in \text{Gal}(k^{sep}/k)$ acts via

$$\chi_{cycl}(\sigma)^{-1} \cdot \sigma \text{ on RHS}$$

where

$$\chi_{cycl} : \text{Gal}(k^{sep}/k) \rightarrow \prod_{l \neq \text{char}(k)} \mathbf{Z}_l^*$$

is the cyclotomic character.

Reformulation (Deligne, Weil II, page 338). For any finite locally constant sheaf \mathcal{F} on X there is a maximal quotient $\mathcal{F} \rightarrow \mathcal{F}''$ with $\mathcal{F}''/X_{\bar{k}}$ a constant sheaf, hence

$$\mathcal{F}'' = (X \rightarrow \text{Spec}(k))^{-1} F''$$

where F'' is a sheaf $\text{Spec}(k)$, i.e., a $\text{Gal}(k^{sep}/k)$ -module. Then

$$H_c^2(X_{\bar{k}}, \mathcal{F}) \rightarrow H_c^2(X_{\bar{k}}, \mathcal{F}'') \rightarrow F''(-1)$$

is an isomorphism.

Proof of Lemma 44.107.1. Let $Y \rightarrow^\varphi X$ be the finite étale Galois covering corresponding to $\text{Ker}(\rho) \subset \pi_1(X, \bar{\eta})$. So

$$\text{Aut}(Y/X) = \text{Im}(\rho)$$

is Galois group. Then $\varphi^* \mathcal{F}_\rho = \underline{M}_Y$ and

$$\varphi_* \varphi^* \mathcal{F}_\rho \rightarrow \mathcal{F}_\rho$$

which gives

$$\begin{aligned} H_c^2(X_{\bar{k}}, \varphi_* \varphi^* \mathcal{F}_\rho) &\rightarrow H_c^2(X_{\bar{k}}, \mathcal{F}_\rho) \\ &= H_c^2(Y_{\bar{k}}, \varphi^* \mathcal{F}_\rho) \\ &= H_c^2(Y_{\bar{k}}, \underline{M}) = \bigoplus_{\text{irred. comp. of } Y_{\bar{k}}} M \end{aligned}$$

$$\text{Im}(\rho) \rightarrow H_c^2(Y_{\bar{k}}, \underline{M}) = \bigoplus_{\text{irred. comp. of } Y_{\bar{k}}} M \rightarrow_{\text{Im}(\rho) \text{ equivalent}} H_c^2(X_{\bar{k}}, \mathcal{F}_\rho) \rightarrow_{\text{trivial action}}^{\text{Im}(\rho)}$$

irreducible curve C/\bar{k} , $H_c^2(C, \underline{M}) = M$.

Since

$$\text{set of irreducible components of } Y_{\bar{k}} = \frac{\text{Im}(\rho)}{\text{Im}(\rho|_{\pi_1(X_{\bar{k}}, \bar{\eta})}}$$

We conclude that $H_c^2(X_{\bar{k}}, \mathcal{F}_\rho)$ is a quotient of $M_{\pi_1(X_{\bar{k}}, \bar{\eta})}$. On the other hand, there is a surjection

$$\begin{aligned} \mathcal{F}_\rho \rightarrow \mathcal{F}'' &= \text{sheaf on } X \text{ associated to} \\ & (M)_{\pi_1(X_{\bar{k}}, \bar{\eta})} \leftarrow \pi_1(X, \bar{\eta}) \\ H_c^2(X_{\bar{k}}, \mathcal{F}_\rho) &\rightarrow M_{\pi_1(X_{\bar{k}}, \bar{\eta})} \end{aligned}$$

The twist in Galois action comes from the fact that $H_c^2(X_{\bar{k}}, \mu_n) = {}^{\text{can}} \mathbf{Z}/n\mathbf{Z}$. \square

Remark 44.107.2. Thus we conclude that if X is also projective then we have functorially in the representation ρ the identifications

$$H^0(X_{\bar{k}}, \mathcal{F}_\rho) = M^{\pi_1(X_{\bar{k}}, \bar{\eta})}$$

and

$$H_c^2(X_{\bar{k}}, \mathcal{F}_\rho) = M_{\pi_1(X_{\bar{k}}, \bar{\eta})}(-1)$$

Of course if X is not projective, then $H_c^0(X_{\bar{k}}, \mathcal{F}_\rho) = 0$.

Proposition 44.107.3. *Let X/k as before but $X_{\bar{k}} \neq \mathbf{P}_{\bar{k}}^1$. The functors $(M, \rho) \mapsto H_c^{2-i}(X_{\bar{k}}, \mathcal{F}_\rho)$ are the left derived functor of $(M, \rho) \mapsto H_c^2(X_{\bar{k}}, \mathcal{F}_\rho)$ so*

$$H_c^{2-i}(X_{\bar{k}}, \mathcal{F}_\rho) = H_i(\pi_1(X_{\bar{k}}, \bar{\eta}), M)(-1)$$

Moreover, there is a derived version, namely

$$R\Gamma_c(X_{\bar{k}}, \mathcal{F}_\rho) = LH_0(\pi_1(X_{\bar{k}}, \bar{\eta}), M(-1)) = M(-1) \otimes_{\Lambda[[\pi_1(X_{\bar{k}}, \bar{\eta})]]}^{\mathbf{L}} \Lambda$$

in $D(\Lambda[[\widehat{\mathbf{Z}}]])$. Similarly, the functors $(M, \rho) \mapsto H^i(X_{\bar{k}}, \mathcal{F}_\rho)$ are the right derived functor of $(M, \rho) \mapsto M^{\pi_1(X_{\bar{k}}, \bar{\eta})}$ so

$$H^i(X_{\bar{k}}, \mathcal{F}_\rho) = H^i(\pi_1(X_{\bar{k}}, \bar{\eta}), M)$$

Moreover, in this case there is a derived version too.

Proof. (Idea) Show both sides are universal δ -functors. \square

Remark 44.107.4. By the proposition and Trivial duality then you get

$$H_c^{2-i}(X_{\bar{k}}, \mathcal{F}_\rho) \times H^i(X_{\bar{k}}, \mathcal{F}_\rho^\wedge(1)) \rightarrow \mathbf{Q}/\mathbf{Z}$$

a perfect pairing. If X is projective then this is Poincare duality.

44.108. Abstract trace formula

Suppose given an extension of profinite groups,

$$1 \rightarrow G \rightarrow \Gamma \xrightarrow{\text{deg}} \widehat{\mathbf{Z}} \rightarrow 1$$

We say Γ has an abstract trace formula if and only if there exist

- (1) an integer $q \geq 1$, and
- (2) for every $d \geq 1$ a finite set S_d and for each $x \in S_d$ a conjugacy class $F_x \in \Gamma$ with $\text{deg}(F_x) = d$

such that the following hold

- (1) for all ℓ not dividing q have $\text{cd}_\ell(G) < \infty$, and
- (2) for all finite rings Λ with $q \in \Lambda^*$, for all finite projective Λ -modules M with continuous Γ -action, for all $n > 0$ we have

$$\sum_{d|n} d \left(\sum_{x \in S_d} \text{Tr}(F_x^{n/d}|_M) \right) = q^n \text{Tr}(F^n|_{M \otimes_{\Lambda[[G]]}^{\mathbf{L}} \Lambda})$$

in Λ^\natural .

Here $M \otimes_{\Lambda[[G]]}^{\mathbf{L}} \Lambda = LH_0(G, M)$ denotes derived homology, and $F = 1$ in $\Gamma/G = \widehat{\mathbf{Z}}$.

Remark 44.108.1. Here are some observations concerning this notion.

- (1) If modeling projective curves then we can use cohomology and we don't need factor q^n .
- (2) The only examples I know are $\Gamma = \pi_1(X, \bar{\eta})$ where X is smooth, geometrically irreducible and $K(\pi, 1)$ over finite field. In this case $q = (\#k)^{\dim X}$. Modulo the proposition, we proved this for curves in this course.
- (3) Given the integer q then the sets S_d are uniquely determined. (You can multiple q by an integer m and then replace S_d by m^d copies of S_d without changing the formula.)

Example 44.108.2. Fix an integer $q \geq 1$

$$\begin{array}{ccccccc} 1 & \rightarrow & G = \widehat{\mathbf{Z}}^{(q)} & \rightarrow & \Gamma & \rightarrow & \widehat{\mathbf{Z}} \rightarrow 1 \\ & & = \prod_{l|q} \mathbf{Z}_l & & F & \mapsto & 1 \end{array}$$

with $FxF^{-1} = ux$, $u \in (\widehat{\mathbf{Z}}^{(q)})^*$. Just using the trivial modules $\mathbf{Z}/m\mathbf{Z}$ we see

$$q^n - (qu)^n \equiv \sum_{d|n} d \#S_d$$

in $\mathbf{Z}/m\mathbf{Z}$ for all $(m, q) = 1$ (up to $u \rightarrow u^{-1}$) this implies $qu = a \in \mathbf{Z}$ and $|a| < q$. The special case $a = 1$ does occur with

$$\Gamma = \pi_1^t(\mathbf{G}_{m, \mathbf{F}_p, \bar{\eta}}), \quad \#S_1 = q - 1, \quad \text{and} \quad \#S_2 = \frac{(q^2 - 1) - (q - 1)}{2}$$

44.109. Automorphic forms and sheaves

References: See especially the amazing papers [Dri83], [Dri84] and [Dri80] by Drinfeld.

Unramified cusp forms. Let k be a finite field of characteristic p . Let X geometrically irreducible projective smooth curve over k . Set $K = k(X)$ equal to the function field of X . Let v be a place of K which is the same thing as a closed point $x \in X$. Let K_v be the completion of K at v , which is the same thing as the fraction field of the completion of the local ring of X at x , i.e., $K_v = f.f.(\widehat{O_{X,x}})$. Denote $O_v \subset K_v$ the ring of integers. We further set

$$O = \prod_v O_v \subset \mathbf{A} = \prod_v' K_v$$

and we let Λ be any ring with p invertible in Λ .

Definition 44.109.1. An unramified cusp form on $GL_2(\mathbf{A})$ with values in Λ^8 is a function

$$f : GL_2(\mathbf{A}) \rightarrow \Lambda$$

such that

- (1) $f(x\gamma) = f(x)$ for all $x \in GL_2(\mathbf{A})$ and all $\gamma \in GL_2(K)$
- (2) $f(ux) = f(x)$ for all $x \in GL_2(\mathbf{A})$ and all $u \in GL_2(O)$

⁸This is likely nonstandard notation.

(3) for all $x \in \text{GL}_2(\mathbf{A})$,

$$\int_{\mathbf{A} \bmod K} f\left(x \begin{pmatrix} 1 & z \\ 0 & 1 \end{pmatrix}\right) dz = 0$$

see [dJ01, Section 4.1] for an explanation of how to make sense out of this for a general ring Λ in which p is invertible.

Hecke Operators. For v a place of K and f an unramified cusp form we set

$$T_v(f)(x) = \int_{g \in M_v} f(g^{-1}x) dg,$$

and

$$U_v(f)(x) = f\left(\begin{pmatrix} \pi_v^{-1} & 0 \\ 0 & \pi_v^{-1} \end{pmatrix} x\right)$$

Notations used: here $\pi_v \in O_v$ is a uniformizer

$$M_v = \{h \in \text{Mat}(2 \times 2, O_v) \mid \det h = \pi_v O_v^*\}$$

and dg is the Haar measure on $\text{GL}_2(K_v)$ with $\int_{\text{GL}_2(O_v)} dg = 1$. Explicitly we have

$$T_v(f)(x) = f\left(\begin{pmatrix} \pi_v^{-1} & 0 \\ 0 & 1 \end{pmatrix} x\right) + \sum_{i=1}^{q_v} f\left(\begin{pmatrix} 1 & 0 \\ -\pi_v^{-1}\lambda_i & \pi_v^{-1} \end{pmatrix} x\right)$$

with $\lambda_i \in O_v$ a set of representatives of $O_v/(\pi_v) = \kappa_v$, $q_v = \#\kappa_v$.

Eigenforms. An *eigenform* f is an unramified cusp form such that some value of f is a unit and $T_v f = t_v f$ and $U_v f = u_v f$ for some (uniquely determined) $t_v, u_v \in \Lambda$.

Theorem 44.109.2. *Given an eigenform f with values in $\overline{\mathbf{Q}}_l$ and eigenvalues $u_v \in \overline{\mathbf{Z}}_l^*$ then there exists*

$$\rho : \pi_1(X) \rightarrow \text{GL}_2(E)$$

continuous, absolutely irreducible where E is a finite extension of \mathbf{Q}_ℓ contained in $\overline{\mathbf{Q}}_l$ such that $t_v = \text{Tr}(\rho(F_v))$, and $u_v = q_v^{-1} \det(\rho(F_v))$ for all places v .

Proof. See [Dri80]. □

Theorem 44.109.3. *Suppose $\mathbf{Q}_l \subset E$ finite, and*

$$\rho : \pi_1(X) \rightarrow \text{GL}_2(E)$$

absolutely irreducible, continuous. Then there exists an eigenform f with values in $\overline{\mathbf{Q}}_l$ whose eigenvalues t_v, u_v satisfy the equalities $t_v = \text{Tr}(\rho(F_v))$ and $u_v = q_v^{-1} \det(\rho(F_v))$.

Proof. See [Dri83]. □

Remark 44.109.4. We now have, thanks to Lafforgue and many other mathematicians, complete theorems like this two above for GL_n and allowing ramification! In other words, the full global Langlands correspondence for GL_n is known for function fields of curves over finite fields. At the same time this does not mean there aren't a lot of interesting questions left to answer about the fundamental groups of curves over finite fields, as we shall see below.

Central character. If f is an eigenform then

$$\chi_f : \begin{array}{ccc} O^* \backslash \mathbf{A}^* / K^* & \rightarrow & \Lambda^* \\ (1, \dots, \pi_v, 1, \dots, 1) & \mapsto & u_v^{-1} \end{array}$$

is called the *central character*. It corresponds to the determinant of ρ via normalizations as above. Set

$$C(\Lambda) = \left\{ \begin{array}{l} \text{unr. cusp forms } f \text{ with coefficients in } \Lambda \\ \text{such that } U_v f = \varphi_v^{-1} f \forall v \end{array} \right\}$$

Proposition 44.109.5. *If Λ is Noetherian then $C(\Lambda)$ is a finitely generated Λ -module. Moreover, if Λ is a field with prime subfield $\mathbf{F} \subset \Lambda$ then*

$$C(\Lambda) = (C(\mathbf{F})) \otimes_{\mathbf{F}} \Lambda$$

compatibly with T_v acting.

Proof. See [dJ01, Proposition 4.7]. □

This proposition trivially implies the following lemma.

Lemma 44.109.6. *Algebraicity of eigenvalues. If Λ is a field then the eigenvalues t_v for $f \in C(\Lambda)$ are algebraic over the prime subfield $\mathbf{F} \subset \Lambda$.*

Proof. Follows from Proposition 44.109.5. □

Combining all of the above we can do the following very useful trick.

Lemma 44.109.7. *Switching l . Let E be a number field. Start with*

$$\rho : \pi_1(X) \rightarrow SL_2(E_\lambda)$$

absolutely irreducible continuous, where λ is a place of E not lying above p . Then for any second place λ' of E not lying above p there exists a finite extension $E'_{\lambda'}$ and a absolutely irreducible continuous representation

$$\rho' : \pi_1(X) \rightarrow SL_2(E'_{\lambda'})$$

which is compatible with ρ in the sense that the characteristic polynomials of all Frobenii are the same.

Note how this is an instance of Deligne’s conjecture!

Proof. To prove the switching lemma use Theorem 44.109.3 to obtain $f \in C(\overline{\mathbf{Q}}_l)$ eigenform ass. to ρ . Next, use Proposition 44.109.5 to see that we may choose $f \in C(E')$ with $E \subset E'$ finite. Next we may complete E' to see that we get $f \in C(E'_{\lambda'})$ eigenform with $E'_{\lambda'}$ a finite extension of $E_{\lambda'}$. And finally we use Theorem 44.109.2 to obtain $\rho' : \pi_1(X) \rightarrow SL_2(E'_{\lambda'})$ abs. irred. and continuous after perhaps enlarging $E'_{\lambda'}$ a bit again. □

Speculation: If for a (topological) ring Λ we have

$$\left(\begin{array}{l} \rho : \pi_1(X) \rightarrow SL_2(\Lambda) \\ \text{abs irred} \end{array} \right) \leftrightarrow \text{eigen forms in } C(\Lambda)$$

then all eigenvalues of $\rho(F_v)$ algebraic (won’t work in an easy way if Λ is a finite ring. Based on the speculation that the Langlands correspondence works more generally than just over fields one arrives at the following conjecture.

Conjecture. (See [dJ01]) For any continuous

$$\rho : \pi_1(X) \rightarrow \mathrm{GL}_n(\mathbf{F}_l[[t]])$$

we have $\#\rho(\pi_1(X_{\bar{k}})) < \infty$.

A rephrasing in the language of sheaves: "For any lisse sheaf of $\overline{\mathbf{F}_l((t))}$ -modules the geom monodromy is finite."

Theorem 44.109.8. *The Conjecture holds if $n \leq 2$.*

Proof. See [dJ01]. □

Theorem 44.109.9. *Conjecture holds if $l > 2n$ modulo some unproven things.*

Proof. See [Gai07]. □

It turns out the conjecture is useful for something. See work of Drinfeld on Kashiwara's conjectures. But there is also the much more down to earth application as follows.

Theorem 44.109.10. (See [dJ01, Theorem 3.5]) *Suppose*

$$\rho_0 : \pi_1(X) \rightarrow \mathrm{GL}_n(\mathbf{F}_l)$$

is a continuous, $l \neq p$. Assume

- (1) *Conj. holds for X ,*
- (2) *$\rho_0|_{\pi_1(X_{\bar{k}})}$ abs. irred., and*
- (3) *l does not divide n .*

Then the universal determination ring R_{univ} of ρ_0 is finite flat over \mathbf{Z}_l .

Explanation: There is a representation $\rho_{\mathrm{univ}} : \pi_1(X) \rightarrow \mathrm{GL}_n(R_{\mathrm{univ}})$ (Univ. Defo ring) R_{univ} loc. complete, residue field \mathbf{F}_l and $(R_{\mathrm{univ}} \rightarrow \mathbf{F}_l) \circ \rho_{\mathrm{univ}} \cong \rho_0$. And given any $R \rightarrow \mathbf{F}_l$, R local complete and $\rho : \pi_1(X) \rightarrow \mathrm{GL}_n(R)$ then there exists $\psi : R_{\mathrm{univ}} \rightarrow R$ such that $\psi \circ \rho_{\mathrm{univ}} \cong \rho$. The theorem says that the morphism

$$\mathrm{Spec}(R_{\mathrm{univ}}) \longrightarrow \mathrm{Spec}(\mathbf{Z}_l)$$

is finite and flat. In particular, such a ρ_0 lifts to a $\rho : \pi_1(X) \rightarrow \mathrm{GL}_n(\overline{\mathbf{Q}}_l)$.

Notes:

- (1) The theorem on deformations is easy.
- (2) Any result towards the conjecture seems hard.
- (3) It would be interesting to have more conjectures on $\pi_1(X)$!

44.110. Counting points

Let X be a smooth, geometrically irreducible, projective curve over k and $q = \#k$. The trace formula gives: there exists algebraic integers w_1, \dots, w_{2g} such that

$$\#X(k_n) = q^n - \sum_{i=1}^{2g_X} w_i^n + 1.$$

If $\sigma \in \mathrm{Aut}(X)$ then for all i , there exists j such that $\sigma(w_i) = w_j$.

Riemann-Hypothesis. For all i we have $|\omega_i| = \sqrt{q}$.

This was formulated by Emil Artin, in 1924, for hyperelliptic curves. Proved by Weil 1940. Weil gave two proofs

- using intersection theory on $X \times X$, using the Hodge index theorem, and

- using the Jacobian of X .

There is another proof whose initial idea is due to Stephanov, and which was given by Bombieri: it uses the function field $k(X)$ and its Frobenius operator (1969). The starting point is that given $f \in k(X)$ one observes that $f^q - f$ is a rational function which vanishes in all the \mathbf{F}_q -rational points of X , and that one can try to use this idea to give an upper bound for the number of points.

44.111. Precise form of Chebotarev

As a first application let us prove a precise form of Chebotarev for a finite étale Galois covering of curves. Let $\varphi : Y \rightarrow X$ be a finite étale Galois covering with group G . This corresponds to a homomorphism

$$\pi_1(X) \longrightarrow G = \text{Aut}(Y/X)$$

Assume $Y_{\bar{k}}$ is irreducible. If $C \subset G$ is a conjugacy class then for all $n > 0$, we have

$$|\#\{x \in X(k_n) \mid F_x \in C\} - \frac{\#C}{\#G} \cdot \#X(k_n)| \leq (\#C)(2g - 2)\sqrt{q^n}$$

(Warning: Please check the coefficient $\#C$ on the right hand side carefully before using.)

Sketch. Write

$$\varphi_*(\overline{\mathbf{Q}}_l) = \oplus_{\pi \in \widehat{G}} \mathcal{F}_\pi$$

where \widehat{G} is the set of isomorphism classes of irred representations of G over $\overline{\mathbf{Q}}_l$. For $\pi \in \widehat{G}$ let $\chi_\pi : G \rightarrow \overline{\mathbf{Q}}_l$ be the character of π . Then

$$H^*(Y_{\bar{k}}, \overline{\mathbf{Q}}_l) = \oplus_{\pi \in \widehat{G}} H^*(Y_{\bar{k}}, \overline{\mathbf{Q}}_l)_\pi =_{(\varphi \text{ finite})} \oplus_{\pi \in \widehat{G}} H^*(X_{\bar{k}}, \mathcal{F}_\pi)$$

If $\pi \neq 1$ then we have

$$H^0(X_{\bar{k}}, \mathcal{F}_\pi) = H^2(X_{\bar{k}}, \mathcal{F}_\pi) = 0, \quad \dim H^1(X_{\bar{k}}, \mathcal{F}_\pi) = (2g_X - 2)d_\pi^2$$

(can get this from trace formula for acting on ...) and we see that

$$\left| \sum_{x \in X(k_n)} \chi_\pi(\mathcal{F}_x) \right| \leq (2g_X - 2)d_\pi^2 \sqrt{q^n}$$

Write $1_C = \sum_\pi a_\pi \chi_\pi$, then $a_\pi = \langle 1_C, \chi_\pi \rangle$, and $a_1 = \langle 1_C, \chi_1 \rangle = \frac{\#C}{\#G}$ where

$$\langle f, h \rangle = \frac{1}{\#G} \sum_{g \in G} f(g) \overline{h(g)}$$

Thus we have the relation

$$\frac{\#C}{\#G} = \|1_C\|^2 = \sum |a_\pi|^2$$

Final step:

$$\begin{aligned} \#\{x \in X(k_n) \mid F_x \in C\} &= \sum_{x \in X(k_n)} 1_C(x) \\ &= \sum_{x \in X(k_n)} \sum_{\pi} a_{\pi} \chi_{\pi}(F_x) \\ &= \underbrace{\frac{\#C}{\#G} \#X(k_n)}_{\text{term for } \pi=1} + \underbrace{\sum_{\pi \neq 1} a_{\pi} \sum_{x \in X(k_n)} \chi_{\pi}(F_x)}_{\text{error term (to be bounded by } E)} \end{aligned}$$

We can bound the error term by

$$\begin{aligned} |E| &\leq \sum_{\substack{\pi \in \widehat{G}, \\ \pi \neq 1}} |a_{\pi}| (2g - 2) d_{\pi}^2 \sqrt{q^n} \\ &\leq \sum_{\pi \neq 1} \frac{\#C}{\#G} (2g_X - 2) d_{\pi}^3 \sqrt{q^n} \end{aligned}$$

By Weil’s conjecture, $\#X(k_n) \sim q^n$. □

44.112. How many primes decompose completely?

This section gives a second application of the Riemann Hypothesis for curves over a finite field. For number theorists it may be nice to look at the paper by Ihara, entitled “How many primes decompose completely in an infinite unramified Galois extension of a global field?”, see [Iha83]. Consider the fundamental exact sequence

$$1 \rightarrow \pi_1(X_{\bar{k}}) \rightarrow \pi_1(X) \xrightarrow{\text{deg}} \widehat{\mathbf{Z}} \rightarrow 1$$

Proposition 44.112.1. *There exists a finite set x_1, \dots, x_n of closed points of X such that that set of all frobenius elements corresponding to these points topologically generate $\pi_1(X)$.*

Another way to state this is: There exist $x_1, \dots, x_n \in |X|$ such that the smallest normal closed subgroup Γ of $\pi_1(X)$ containing 1 frobenius element for each x_i is all of $\pi_1(X)$. i.e., $\Gamma = \pi_1(X)$.

Proof. Pick $N \gg 0$ and let

$$\{x_1, \dots, x_n\} = \begin{array}{l} \text{set of all closed points of} \\ X \text{ of degree } \leq N \text{ over } k \end{array}$$

Let $\Gamma \subset \pi_1(X)$ be as in the variant statement for these points. Assume $\Gamma \neq \pi_1(X)$. Then we can pick a normal open subgroup U of $\pi_1(X)$ containing Γ with $U \neq \pi_1(X)$. By R.H. for X our set of points will have some x_{i_1} of degree N , some x_{i_2} of degree $N - 1$. This shows $\text{deg} : \Gamma \rightarrow \widehat{\mathbf{Z}}$ is surjective and so the same holds for U . This exactly means if $Y \rightarrow X$ is the finite étale Galois covering corresponding to U , then $Y_{\bar{k}}$ irreducible. Set $G = \text{Aut}(Y/X)$. Picture

$$Y \xrightarrow{G} X, \quad G = \pi_1(X)/U$$

By construction all points of X of degree $\leq N$, split completely in Y . So, in particular

$$\#Y(k_N) \geq (\#G)\#X(k_N)$$

Use R.H. on both sides. So you get

$$q^N + 1 + 2g_Y q^{N/2} \geq \#G\#X(k_N) \geq \#G(q^N + 1 - 2g_X q^{N/2})$$

Since $2g_Y - 2 = (\#G)(2g_X - 2)$, this means

$$q^N + 1 + (\#G)(2g_X - 1 + 1)q^{N/2} \geq \#G(q^N + 1 - 2g_X q^{N/2})$$

Thus we see that G has to be the trivial group if N is large enough. □

Weird Question. Set $W_X = \text{deg}^{-1}(\mathbf{Z}) \subset \pi_1(X)$. Is it true that for some finite set of closed points x_1, \dots, x_n of X the set of all Frobenii corresponding to these points *algebraically* generate W_X ?

By a Baire category argument this translates into the same question for all Frobenii.

44.113. How many points are there really?

If the genus of the curve is large relative to q , then the main term in the formula $\#X(k) = q - \sum \omega_i + 1$ is not q but the second term $\sum \omega_i$ which can (a priori) have size about $2g_X \sqrt{q}$. In the paper [VD83] the authors Drinfeld and Vladut show that this maximum is (as predicted by Ihara earlier) actually at most about $g\sqrt{q}$.

Fix q and let k be a field with k elements. Set

$$A(q) = \limsup_{g_X \rightarrow \infty} \frac{\#X(k)}{g_X}$$

where X runs over geometrically irreducible smooth projective curves over k . With this definition we have the following results:

- RH $\Rightarrow A(q) \leq 2\sqrt{q}$
- Ihara $\Rightarrow A(q) \leq \sqrt{2q}$
- DV $\Rightarrow A(q) \leq \sqrt{q} - 1$ (actually this is sharp if q is a square)

Proof. Given X let w_1, \dots, w_{2g} and $g = g_X$ be as before. Set $\alpha_i = \frac{w_i}{\sqrt{q}}$, so $|\alpha_i| = 1$. If α_i occurs then $\bar{\alpha}_i = \alpha_i^{-1}$ also occurs. Then

$$N = \#X(k) \leq X(k_r) = q^r + 1 - \left(\sum_i \alpha_i^r\right)q^{r/2}$$

Rewriting we see that for every $r \geq 1$

$$-\sum_i \alpha_i^r \geq Nq^{-r/2} - q^{r/2} - q^{-r/2}$$

Observe that

$$0 \leq |\alpha_i^n + \alpha_i^{n-1} + \dots + \alpha_i + 1|^2 = (n+1) + \sum_{j=1}^n (n+1-j)(\alpha_i^j + \alpha_i^{-j})$$

So

$$\begin{aligned} 2g(n+1) &\geq -\sum_i \left(\sum_{j=1}^n (n+1-j)(\alpha_i^j + \alpha_i^{-j}) \right) \\ &= -\sum_{j=1}^n (n+1-j) \left(\sum_i \alpha_i^j + \sum_i \alpha_i^{-j} \right) \end{aligned}$$

Take half of this to get

$$\begin{aligned} g(n+1) &\geq -\sum_{j=1}^n (n+1-j) \left(\sum_i \alpha_i^j \right) \\ &\geq N \sum_{j=1}^n (n+1-j) q^{-j/2} - \sum_{j=1}^n (n+1-j) (q^{j/2} + q^{-j/2}) \end{aligned}$$

This gives

$$\frac{N}{g} \leq \left(\sum_{j=1}^n \frac{n+1-j}{n+1} q^{-j/2} \right)^{-1} \cdot \left(1 + \frac{1}{g} \sum_{j=1}^n \frac{n+1-j}{n+1} (q^{j/2} + q^{-j/2}) \right)$$

Fix n let $g \rightarrow \infty$

$$A(q) \leq \left(\sum_{j=1}^n \frac{n+1-j}{n+1} q^{-j/2} \right)^{-1}$$

So

$$A(q) \leq \lim_{n \rightarrow \infty} (\dots) = \left(\sum_{j=1}^{\infty} q^{-j/2} \right)^{-1} = \sqrt{q} - 1$$

Crystalline Cohomology

45.1. Introduction

This chapter is based on a lecture series given by Johan de Jong held in 2012 at Columbia University. The goals of this chapter are to give a quick introduction to crystalline cohomology. A reference is the book [Ber74].

We have moved the more elementary purely algebraic discussion of divided power rings to a preliminary chapter as it is also useful in discussing Tate resolutions in commutative algebra. Please see Divided Power Algebra, Section 23.1.

45.2. Divided power envelope

The construction of the following lemma will be dubbed the divided power envelope. It will play an important role later.

Lemma 45.2.1. *Let (A, I, γ) be a divided power ring. Let $A \rightarrow B$ be a ring map. Let $J \subset B$ be an ideal with $IB \subset J$. There exists a homomorphism of divided power rings*

$$(A, I, \gamma) \longrightarrow (D, \bar{J}, \bar{\gamma})$$

such that

$$\mathrm{Hom}_{(A, I, \gamma)}((D, \bar{J}, \bar{\gamma}), (C, K, \delta)) = \mathrm{Hom}_{(A, I)}((B, J), (C, K))$$

functorially in the divided power algebra (C, K, δ) over (A, I, γ) . Here the LHS is morphisms of divided power rings over (A, I, γ) and the RHS is morphisms of (ring, ideal) pairs over (A, I) .

Proof. Denote \mathcal{C} the category of divided power rings (C, K, δ) . Consider the functor $F : \mathcal{C} \rightarrow \text{Sets}$ defined by

$$F(C, K, \delta) = \left\{ (\varphi, \psi) \left| \begin{array}{l} \varphi : (A, I, \gamma) \rightarrow (C, K, \delta) \text{ homomorphism of divided power rings} \\ \psi : (B, J) \rightarrow (C, K) \text{ an } A\text{-algebra homomorphism with } \psi(J) \subset K \end{array} \right. \right\}$$

We will show that Divided Power Algebra, Lemma 23.3.3 applies to this functor which will prove the lemma. Suppose that $(\varphi, \psi) \in F(C, K, \delta)$. Let $C' \subset C$ be the subring generated by $\varphi(A)$, $\psi(B)$, and $\delta_n(\psi(f))$ for all $f \in J$. Let $K' \subset K \cap C'$ be the ideal of C' generated by $\varphi(I)$ and $\delta_n(\psi(f))$ for $f \in J$. Then $(C', K', \delta|_{K'})$ is a divided power ring and C' has cardinality bounded by the cardinal $\kappa = |A| \otimes |B|^{\aleph_0}$. Moreover, φ factors as $A \rightarrow C' \rightarrow C$ and ψ factors as $B \rightarrow B' \rightarrow B$. This proves assumption (1) of Divided Power Algebra, Lemma 23.3.3 holds. Assumption (2) is clear as limits in the category of divided power rings commute with the forgetful functor $(C, K, \delta) \mapsto (C, K)$, see Divided Power Algebra, Lemma 23.3.2 and its proof. \square

Definition 45.2.2. Let (A, I, γ) be a divided power ring. Let $A \rightarrow B$ be a ring map. Let $J \subset B$ be an ideal with $IB \subset J$. The divided power algebra $(D, \bar{J}, \bar{\gamma})$ constructed in Lemma 45.2.1 is called the *divided power envelope of J in B relative to (A, I, γ)* and is denoted $D_B(J)$ or $D_{B,\gamma}(J)$.

Let $(A, I, \gamma) \rightarrow (C, K, \delta)$ be a homomorphism of divided power rings. The universal property of $D_{B,\gamma}(J) = (D, \bar{J}, \bar{\gamma})$ is

$$\begin{array}{ccc} \text{ring maps } B \rightarrow C & & \text{divided power homomorphisms} \\ \text{which map } J \text{ into } K & \longleftrightarrow & (D, \bar{J}, \bar{\gamma}) \rightarrow (C, K, \delta) \end{array}$$

and the correspondence is given by precomposing with the map $B \rightarrow D$ which corresponds to id_D . Here are some properties of $(D, \bar{J}, \bar{\gamma})$ which follow directly from the universal property. There are A -algebra maps

$$(45.2.2.1) \quad B \longrightarrow D \longrightarrow B/J$$

The first arrow maps J into \bar{J} and \bar{J} is the kernel of the second arrow. The elements $\bar{\gamma}_n(x)$ where $n > 0$ and x is an element in the image of $J \rightarrow D$ generate \bar{J} as an ideal in D and generate D as a B -algebra.

Lemma 45.2.3. *Let (A, I, γ) be a divided power ring. Let $\varphi : B' \rightarrow B$ be a surjection of A -algebras with kernel K . Let $IB \subset J \subset B$ be an ideal. Let $J' \subset B'$ be the inverse image of J . Write $D_{B',\gamma}(J') = (D', \bar{J}', \bar{\gamma}')$. Then $D_{B,\gamma}(J) = (D'/K', \bar{J}'/K', \bar{\gamma}')$ where K' is the ideal generated by the elements $\bar{\gamma}_n(k)$ for $n \geq 1$ and $k \in K$.*

Proof. Write $D_{B,\gamma}(J) = (D, \bar{J}, \bar{\gamma})$. The universal property of D' gives us a homomorphism $D' \rightarrow D$ of divided power algebras. As $B' \rightarrow B$ and $J' \rightarrow J$ are surjective, we see that $D' \rightarrow D$ is surjective (see remarks above). It is clear that $\bar{\gamma}_n(k)$ is in the kernel for $n \geq 1$ and $k \in K$, i.e., we obtain a homomorphism $D'/K' \rightarrow D$. Conversely, there exists a divided power structure on $\bar{J}'/K' \subset D'/K'$, see Divided Power Algebra, Lemma 23.4.3. Hence the universal property of D gives an inverse $D \rightarrow D'/K'$ and we win. \square

In the situation of Definition 45.2.2 we can choose a surjection $P \rightarrow B$ where P is a polynomial algebra over A and let $J' \subset P$ be the inverse image of J . The previous lemma describes $D_{B,\gamma}(J)$ in terms of $D_{P,\gamma}(J')$. Note that γ extends to a divided power structure γ' on IP by Divided Power Algebra, Lemma 23.4.2. Hence $D_{P,\gamma}(J') = D_{P,\gamma'}(J')$ is an example of a special case of divided power envelopes we describe in the following lemma.

Lemma 45.2.4. *Let (B, I, γ) be a divided power algebra. Let $I \subset J \subset B$ be an ideal. Let $(D, \bar{J}, \bar{\gamma})$ be the divided power envelope of J relative to γ . Choose elements $f_t \in J$, $t \in T$ such that $J = I + (f_t)$. Then there exists a surjection*

$$\Psi : B\langle x_t \rangle \longrightarrow D$$

of divided power rings mapping x_t to the image of f_t in D . The kernel of Ψ is generated by the elements $x_t - f_t$ and all

$$\delta_n \left(\sum r_t x_t - r_0 \right)$$

whenever $\sum r_t f_t = r_0$ in B for some $r_t \in B$, $r_0 \in I$.

Proof. In the statement of the lemma we think of $B\langle x_t \rangle$ as a divided power ring with ideal $J' = IB\langle x_t \rangle + B\langle x_t \rangle_+$, see Divided Power Algebra, Remark 23.5.2. The existence of Ψ follows from the universal property of divided power polynomial rings. Surjectivity of Ψ follows from the fact that its image is a divided power subring of D , hence equal to D by the universal property of D . It is clear that $x_t - f_t$ is in the kernel. Set

$$\mathcal{R} = \{(r_0, r_t) \in I \oplus \bigoplus_{t \in T} B \mid \sum r_t f_t = r_0 \text{ in } B\}$$

If $(r_0, r_t) \in \mathcal{R}$ then it is clear that $\sum r_t x_t - r_0$ is in the kernel. As Ψ is a homomorphism of divided power rings and $\sum r_t x_t = r_0 \in J'$ it follows that $\delta_n(\sum r_t x_t - r_0)$ is in the kernel as well. Let $K \subset B\langle x_t \rangle$ be the ideal generated by $x_t - f_t$ and the elements $\delta_n(\sum r_t x_t - r_0)$ for $(r_0, r_t) \in \mathcal{R}$. To show that $K = \text{Ker}(\Psi)$ it suffices to show that δ extends to $B\langle x_t \rangle/K$. Namely, if so the universal property of D gives a map $D \rightarrow B\langle x_t \rangle/K$ inverse to Ψ . Hence we have to show that $K \cap J'$ is preserved by δ_n , see Divided Power Algebra, Lemma 23.4.3. Let $K' \subset B\langle x_t \rangle$ be the ideal generated by the elements

- (1) $\delta_m(\sum r_t x_t - r_0)$ where $m > 0$ and $(r_0, r_t) \in \mathcal{R}$,
- (2) $x_{t'}^{[m]}(x_t - f_t)$ where $m > 0$ and $t', t \in I$.

We claim that $K' = K \cap J'$. The claim proves that $K \cap J'$ is preserved by δ_n , $n > 0$ by the criterion of Divided Power Algebra, Lemma 23.4.3 (2)(c) and a computation of δ_n of the elements listed which we leave to the reader. To prove the claim note that $K' \subset K \cap J'$. Conversely, if $h \in K \cap J'$ then, modulo K' we can write

$$h = \sum r_t(x_t - f_t)$$

for some $r_t \in B$. As $h \in K \cap J' \subset J'$ we see that $r_0 = \sum r_t f_t \in I$. Hence $(r_0, r_t) \in \mathcal{R}$ and we see that

$$h = \sum r_t x_t - r_0$$

is in K' as desired. □

Lemma 45.2.5. *Let (A, I, γ) be a divided power ring. Let B be an A -algebra and $IB \subset J \subset B$ an ideal. Let x_i be a set of variables. Then*

$$D_{B[x_i], \gamma}(JB[x_i] + (x_i)) = D_{B, \gamma}(J)\langle x_i \rangle$$

Proof. One possible proof is to deduce this from Lemma 45.2.4 as any relation between x_i in $B[x_i]$ is trivial. On the other hand, the lemma follows from the universal property of the divided power polynomial algebra and the universal property of divided power envelopes. □

Conditions (1) and (2) of the following lemma hold if $B \rightarrow B'$ is flat at all primes of $V(IB') \subset \text{Spec}(B')$ and is very closely related to that condition, see Algebra, Lemma 10.95.8. It in particular says that taking the divided power envelope commutes with localization.

Lemma 45.2.6. *Let (A, I, γ) be a divided power ring. Let $B \rightarrow B'$ be a homomorphism of A -algebras. Assume that*

- (1) $B/IB \rightarrow B'/IB'$ is flat, and
- (2) $\text{Tor}_1^B(B', B/IB) = 0$.

Then for any ideal $IB \subset J \subset B$ the canonical map

$$D_B(J) \otimes_B B' \longrightarrow D_{B'}(JB')$$

is an isomorphism.

Proof. Set $D = D_B(J)$ and denote $\bar{J} \subset D$ its divided power ideal with divided power structure $\bar{\gamma}$. The universal property of D produces a B -algebra map $D \rightarrow D_{B'}(JB')$, whence a map as in the lemma. It suffices to show that the divided powers $\bar{\gamma}$ extend to $D \otimes_B B'$ since then the universal property of $D_{B'}(JB')$ will produce a map $D_{B'}(JB') \rightarrow D \otimes_B B'$ inverse to the one in the lemma.

Choose a surjection $P \rightarrow B'$ where P is a polynomial algebra over B . In particular $B \rightarrow P$ is flat, hence $D \rightarrow D \otimes_B P$ is flat by Algebra, Lemma 10.38.6. Then $\bar{\gamma}$ extends to $D \otimes_B P$ by Divided Power Algebra, Lemma 23.4.2; we will denote this extension $\bar{\gamma}$ also. Set $\mathfrak{a} = \text{Ker}(P \rightarrow B')$ so that we have the short exact sequence

$$0 \rightarrow \mathfrak{a} \rightarrow P \rightarrow B' \rightarrow 0$$

Thus $\text{Tor}_1^B(B', B/IB) = 0$ implies that $\mathfrak{a} \cap IP = I\mathfrak{a}$. Now we have the following commutative diagram

$$\begin{array}{ccccc} B/J \otimes_B \mathfrak{a} & \xrightarrow{\beta} & B/J \otimes_B P & \longrightarrow & B/J \otimes_B B' \\ \uparrow & & \uparrow & & \uparrow \\ D \otimes_B \mathfrak{a} & \xrightarrow{\alpha} & D \otimes_B P & \longrightarrow & D \otimes_B B' \\ \uparrow & & \uparrow & & \uparrow \\ \bar{J} \otimes_B \mathfrak{a} & \longrightarrow & \bar{J} \otimes_B P & \longrightarrow & \bar{J} \otimes_B B' \end{array}$$

This diagram is exact even with 0's added at the top and the right. We have to show the divided powers on the ideal $\bar{J} \otimes_B P$ preserve the ideal $\text{Im}(\alpha) \cap \bar{J} \otimes_B P$, see Divided Power Algebra, Lemma 23.4.3. Consider the exact sequence

$$0 \rightarrow \mathfrak{a}/I\mathfrak{a} \rightarrow P/IP \rightarrow B'/IB' \rightarrow 0$$

(which uses that $\mathfrak{a} \cap IP = I\mathfrak{a}$ as seen above). As B'/IB' is flat over B/IB this sequence remains exact after applying $B/J \otimes_{B/IB} -$, see Algebra, Lemma 10.38.11. Hence

$$\text{Ker}(B/J \otimes_{B/IB} \mathfrak{a}/I\mathfrak{a} \rightarrow B/J \otimes_{B/IB} P/IP) = \text{Ker}(\mathfrak{a}/J\mathfrak{a} \rightarrow P/JP)$$

is zero. Thus β is injective. It follows that $\text{Im}(\alpha) \cap \bar{J} \otimes_B P$ is the image of $\bar{J} \otimes_B \mathfrak{a}$. Now if $f \in \bar{J}$ and $a \in \mathfrak{a}$, then $\bar{\gamma}_n(f \otimes a) = \bar{\gamma}_n(f) \otimes a^n$ hence the result is clear. \square

The following lemma is a special case of [dJ95, Proposition 2.1.7] which in turn is a generalization of [Ber74, Proposition 2.8.2].

Lemma 45.2.7. *Let $(B, I, \gamma) \rightarrow (B', I', \gamma')$ be a homomorphism of divided power rings. Let $I \subset J \subset B$ and $I' \subset J' \subset B'$ be ideals. Assume*

- (1) $B/I \rightarrow B'/I'$ is flat, and
- (2) $J' = JB' + I'$.

Then the canonical map

$$D_{B,\gamma}(J) \otimes_B B' \longrightarrow D_{B',\gamma'}(J')$$

is an isomorphism.

Proof. Set $D = D_B(J)$ and denote $\bar{J} \subset D$ its divided power ideal with divided power structure $\bar{\gamma}$. The universal property of D produces a homomorphism of divided power rings $D \rightarrow D_{B'}(J')$, whence a map as in the lemma. It suffices to show that there exist divided powers on the image of $D \otimes_B I' + \bar{J} \otimes_B B' \rightarrow D \otimes_B B'$ compatible with $\bar{\gamma}$ and γ' since then the universal property of $D_{B'}(J')$ will produce a map $D_{B'}(J') \rightarrow D \otimes_B B'$ inverse to the one in the lemma.

Choose elements $f_t \in J$ which generate J/I . Set $\mathcal{R} = \{(r_0, r_t) \in I \oplus \bigoplus_{t \in T} B \mid \sum r_t f_t = r_0 \text{ in } B\}$ as in the proof of Lemma 45.2.4. This lemma shows that

$$D = B\langle x_t \rangle / K$$

where K is generated by the elements $x_t - f_t$ and $\delta_n(\sum r_t x_t - r_0)$ for $(r_0, r_t) \in \mathcal{R}$. Thus we see that

$$(45.2.7.1) \quad D \otimes_B B' = B'\langle x_t \rangle / K'$$

where K' is generated by the images in $B'\langle x_t \rangle$ of the generators of K listed above. Let $f'_t \in B'$ be the image of f_t . By assumption (1) we see that the elements $f'_t \in J'$ generate J'/I' and we see that $x_t - f'_t \in K'$. Set

$$\mathcal{R}' = \{(r'_0, r'_t) \in I' \oplus \bigoplus_{t \in T} B' \mid \sum r'_t f'_t = r'_0 \text{ in } B'\}$$

To finish the proof we have to show that $\delta'_n(\sum r'_t x_t - r'_0) \in K'$ for $(r'_0, r'_t) \in \mathcal{R}'$, because then the presentation (45.2.7.1) of $D \otimes_B B'$ is identical to the presentation of $D_{B', \gamma'}(J')$ obtain in Lemma 45.2.4 from the generators f'_t . Suppose that $(r'_0, r'_t) \in \mathcal{R}'$. Then $\sum r'_t f'_t = 0$ in B'/I' . As $B/I \rightarrow B'/I'$ is flat by assumption (1) we can apply the equational criterion of flatness (Algebra, Lemma 10.38.10) to see that there exist an $m > 0$ and $r_{jt} \in B$ and $c_j \in B'$, $j = 1, \dots, m$ such that

$$r_{j0} = \sum r_{jt} f_t \in I \text{ for } j = 1, \dots, m, \quad \text{and} \quad r'_t = \sum c_j r_{jt}.$$

Note that this also implies that $r'_0 = \sum c_j r_{j0}$. Then we have

$$\begin{aligned} \delta'_n(\sum r'_t x_t - r'_0) &= \delta'_n(\sum c_j (\sum r_{jt} x_t - r_{j0})) \\ &= \sum c_1^{n_1} \dots c_m^{n_m} \delta_{n_1}(\sum r_{1t} x_t - r_{10}) \dots \delta_{n_m}(\sum r_{mt} x_t - r_{m0}) \end{aligned}$$

where the sum is over $n_1 + \dots + n_m = n$. This proves what we want. □

45.3. Some explicit divided power thickenings

The constructions in this section will help us to define the connection on a crystal in modules on the crystalline site.

Lemma 45.3.1. *Let (A, I, γ) be a divided power ring. Let M be an A -module. Let $B = A \oplus M$ as an A -algebra where M is an ideal of square zero and set $J = I \oplus M$. Set*

$$\delta_n(x + z) = \gamma_n(x) + \gamma_{n-1}(x)z$$

for $x \in I$ and $z \in M$. Then δ is a divided power structure and $A \rightarrow B$ is a homomorphism of divided power rings from (A, I, γ) to (B, J, δ) .

Proof. We have to check conditions (1) – (5) of Divided Power Algebra, Definition 23.2.1. We will prove this directly for this case, but please see the proof of the next

lemma for a method which avoids calculations. Conditions (1) and (3) are clear. Condition (2) follows from

$$\begin{aligned} \delta_n(x+z)\delta_m(x+z) &= (\gamma_n(x) + \gamma_{n-1}(x)z)(\gamma_m(x) + \gamma_{m-1}(x)z) \\ &= \gamma_n(x)\gamma_m(x) + \gamma_n(x)\gamma_{m-1}(x)z + \gamma_{n-1}(x)\gamma_m(x)z \\ &= \frac{(n+m)!}{n!m!}\gamma_{n+m}(x) + \left(\frac{(n+m-1)!}{n!(m-1)!} + \frac{(n+m-1)!}{(n-1)!m!}\right)\gamma_{n+m-1}(x)z \\ &= \frac{(n+m)!}{n!m!}\delta_{n+m}(x+z) \end{aligned}$$

Condition (5) follows from

$$\begin{aligned} \delta_n(\delta_m(x+z)) &= \delta_n(\gamma_m(x) + \gamma_{m-1}(x)z) \\ &= \gamma_n(\gamma_m(x)) + \gamma_{n-1}(\gamma_m(x))\gamma_{m-1}(x)z \\ &= \frac{(nm)!}{n!(m!)^n}\gamma_{nm}(x) + \frac{((n-1)m)!}{(n-1)!(m!)^{n-1}}\gamma_{(n-1)m}(x)\gamma_{m-1}(x)z \\ &= \frac{(nm)!}{n!(m!)^n}(\gamma_{nm}(x) + \gamma_{nm-1}(x)z) \end{aligned}$$

by elementary number theory. To prove (4) we have to see that

$$\delta_n(x+x'+z+z') = \gamma_n(x+x') + \gamma_{n-1}(x+x')(z+z')$$

is equal to

$$\sum_{i=0}^n (\gamma_i(x) + \gamma_{i-1}(x)z)(\gamma_{n-i}(x') + \gamma_{n-i-1}(x')z')$$

This follows easily on collecting the coefficients of 1, z, and z' and using condition (4) for γ . □

Lemma 45.3.2. *Let (A, I, γ) be a divided power ring. Let M, N be A -modules. Let $q : M \times M \rightarrow N$ be an A -bilinear map. Let $B = A \oplus M \oplus N$ as an A -algebra with multiplication*

$$(x, z, w) \cdot (x', z', w') = (xx', xz' + x'z, xw' + x'w + q(z, z') + q(z', z))$$

and set $J = I \oplus M \oplus N$. Set

$$\delta_n(x, z, w) = (\gamma_n(x), \gamma_{n-1}(x)z, \gamma_{n-1}(z)w + \gamma_{n-2}(x)q(z, z))$$

for $(a, m, n) \in J$. Then δ is a divided power structure and $A \rightarrow B$ is a homomorphism of divided power rings from (A, I, γ) to (B, J, δ) .

Proof. Suppose we want to prove that property (4) of Divided Power Algebra, Definition 23.2.1 is satisfied. Pick (x, z, w) and (x', z', w') in J . Pick a map

$$A_0 = \mathbf{Z}\langle s, s' \rangle \longrightarrow A, \quad s \longmapsto x, s' \longmapsto x'$$

which is possible by the universal property of divided power polynomial rings. Set $M_0 = A_0 \oplus A_0$ and $N_0 = A_0 \oplus A_0 \oplus M_0 \otimes_{A_0} M_0$. Let $q_0 : M_0 \times M_0 \rightarrow N_0$ be the obvious map. Define $M_0 \rightarrow M$ as the A_0 -linear map which sends the basis vectors of M_0 to z and z' . Define $N_0 \rightarrow N$ as the A_0 linear map which sends the first two basis vectors of N_0 to w and w' and uses $M_0 \otimes_{A_0} M_0 \rightarrow M \otimes_A M \xrightarrow{q} N$ on the last summand. Then we see that it suffices to prove the identity (4) for the situation (A_0, M_0, N_0, q_0) . Similarly for the other identities. This reduces us to the case of a

Z-torsion free ring A and A -torsion free modules. In this case all we have to do is show that

$$n!\delta_n(x, z, w) = (x, z, w)^n$$

in the ring A , see Divided Power Algebra, Lemma 23.2.2. To see this note that

$$(x, z, w)^2 = (x^2, 2xz, 2xw + 2q(z, z))$$

and by induction

$$(x, z, w)^n = (x^n, nx^{n-1}z, nx^{n-1}w + n(n-1)x^{n-2}q(z, z))$$

On the other hand,

$$n!\delta_n(x, z, w) = (n!\gamma_n(x), n!\gamma_{n-1}(x)z, n!\gamma_{n-1}(x)w + n!\gamma_{n-2}(x)q(z, z))$$

which matches. This finishes the proof. \square

45.4. Compatibility

This section isn't required reading; it explains how our discussion fits with that of [Ber74]. Consider the following technical notion.

Definition 45.4.1. Let (A, I, γ) and (B, J, δ) be divided power rings. Let $A \rightarrow B$ be a ring map. We say δ is compatible with γ if there exists a divided power structure $\bar{\gamma}$ on $J + IB$ such that

$$(A, I, \gamma) \rightarrow (B, J + IB, \bar{\gamma}) \quad \text{and} \quad (B, J, \delta) \rightarrow (B, J + IB, \bar{\gamma})$$

are homomorphisms of divided power rings.

Let p be a prime number. Let (A, I, γ) be a divided power ring. Let $A \rightarrow C$ be a ring map with p nilpotent in C . Assume that γ extends to IC (see Divided Power Algebra, Lemma 23.4.2). In this situation, the (big affine) crystalline site of $\text{Spec}(C)$ over $\text{Spec}(A)$ as defined in [Ber74] is the opposite of the category of systems

$$(B, J, \delta, A \rightarrow B, C \rightarrow B/J)$$

where

- (1) (B, J, δ) is a divided power ring with p nilpotent in B ,
- (2) δ is compatible with γ , and
- (3) the diagram

$$\begin{array}{ccc} B & \longrightarrow & B/J \\ \uparrow & & \uparrow \\ A & \longrightarrow & C \end{array}$$

is commutative.

The conditions “ γ extends to C and δ compatible with γ ” are used in [Ber74] to insure that the crystalline cohomology of $\text{Spec}(C)$ is the same as the crystalline cohomology of $\text{Spec}(C/IC)$. We will avoid this issue by working exclusively with C such that $IC = 0$ ¹. In this case, for a system $(B, J, \delta, A \rightarrow B, C \rightarrow B/J)$ as above, the commutativity of the displayed diagram above implies $IB \subset J$ and compatibility is equivalent to the condition that $(A, I, \gamma) \rightarrow (B, J, \delta)$ is a homomorphism of divided power rings.

¹Of course there will be a price to pay.

45.5. Affine crystalline site

In this section we discuss the algebraic variant of the crystalline site. Our basic situation in which we discuss this material will be as follows.

Situation 45.5.1. Here p is a prime number, (A, I, γ) is a divided power ring such that A is a $\mathbf{Z}_{(p)}$ -algebra, and $A \rightarrow C$ is a ring map such that $IC = 0$ and such that p is nilpotent in C .

Usually the prime number p will be contained in the divided power ideal I .

Definition 45.5.2. In Situation 45.5.1.

- (1) A *divided power thickening* of C over (A, I, γ) is a homomorphism of divided power algebras $(A, I, \gamma) \rightarrow (B, J, \delta)$ such that p is nilpotent in B and a ring map $C \rightarrow B/J$ such that

$$\begin{array}{ccc}
 B & \longrightarrow & B/J \\
 \uparrow & & \uparrow \\
 & & C \\
 & & \uparrow \\
 A & \longrightarrow & A/I
 \end{array}$$

is commutative.

- (2) A *homomorphism of divided power thickenings*

$$(B, J, \delta, C \rightarrow B/J) \rightarrow (B', J', \delta', C \rightarrow B'/J')$$

is a homomorphism $\varphi : B \rightarrow B'$ of divided power A -algebras such that $C \rightarrow B/J \rightarrow B'/J'$ is the given map $C \rightarrow B'/J'$.

- (3) We denote $\text{CRIS}(C/A, I, \gamma)$ or simply $\text{CRIS}(C/A)$ the category of divided power thickenings of C over (A, I, γ) .
- (4) We denote $\text{Cris}(C/A, I, \gamma)$ or simply $\text{Cris}(C/A)$ the full subcategory consisting of $(B, J, \delta, C \rightarrow B/J)$ such that $C \rightarrow B/J$ is an isomorphism. We often denote such an object $(B \rightarrow C, \delta)$ with $J = \text{Ker}(B \rightarrow C)$ being understood.

Note that for a divided power thickening (B, J, δ) as above the ideal J is locally nilpotent, see Divided Power Algebra, Lemma 23.2.6. There is a canonical functor

$$(45.5.2.1) \quad \text{CRIS}(C/A) \longrightarrow C\text{-algebras}, \quad (B, J, \delta) \longmapsto B/J$$

This category does not have equalizers or fibre products in general. It also doesn't have an initial object (= empty colimit) in general.

Lemma 45.5.3. *In Situation 45.5.1.*

- (1) $\text{CRIS}(C/A)$ has products,
- (2) $\text{CRIS}(C/A)$ has all finite nonempty colimits and (45.5.2.1) commutes with these, and
- (3) $\text{Cris}(C/A)$ has all finite nonempty colimits and $\text{Cris}(C/A) \rightarrow \text{CRIS}(C/A)$ commutes with them.

Proof. The empty product is $(C, 0, \emptyset)$. If (B_t, J_t, δ_t) is a family of objects of $\text{CRIS}(C/A)$ then we can form the product $(\prod B_t, \prod J_t, \prod \delta_t)$ as in Divided Power Algebra, Lemma 23.3.4. The map $C \rightarrow \prod B_t / \prod J_t = \prod B_t / J_t$ is clear.

Given two objects (B, J, γ) and (B', J', γ') of $\text{CRIS}(C/A)$ we can form a cocartesian diagram

$$\begin{array}{ccc} (B, J, \delta) & \longrightarrow & (B'', J'', \delta'') \\ \uparrow & & \uparrow \\ (A, I, \gamma) & \longrightarrow & (B', J', \delta') \end{array}$$

in the category of divided power rings. Then we see that we have

$$B''/J'' = B/J \otimes_{A/I} B'/J' \longleftarrow C \otimes_{A/I} C$$

see Divided Power Algebra, Remark 23.3.5. Denote $J'' \subset K \subset B''$ the ideal such that

$$\begin{array}{ccc} B''/J'' & \longrightarrow & B''/K \\ \uparrow & & \uparrow \\ C \otimes_{A/I} C & \longrightarrow & C \end{array}$$

is a pushout, i.e., $B''/K \cong B/J \otimes_C B'/J'$. Let $D_{B''}(K) = (D, \bar{K}, \bar{\delta})$ be the divided power envelope of K in B'' relative to (B'', J'', δ'') . Then it is easily verified that $(D, \bar{K}, \bar{\delta})$ is a coproduct of (B, J, δ) and (B', J', δ') in $\text{CRIS}(C/A)$.

Next, we come to coequalizers. Let $\alpha, \beta : (B, J, \delta) \rightarrow (B', J', \delta')$ be morphisms of $\text{CRIS}(C/A)$. Consider $B'' = B'/(\alpha(b) - \beta(b))$. Let $J'' \subset B''$ be the image of J' . Let $D_{B''}(J'') = (D, \bar{J}, \bar{\delta})$ be the divided power envelope of J'' in B'' relative to (B', J', δ') . Then it is easily verified that $(D, \bar{J}, \bar{\delta})$ is the coequalizer of (B, J, δ) and (B', J', δ') in $\text{CRIS}(C/A)$.

By Categories, Lemma 4.18.6 we have all finite nonempty colimits in $\text{CRIS}(C/A)$. The constructions above shows that (45.5.2.1) commutes with them. This formally implies part (3) as $\text{Cris}(C/A)$ is the fibre category of (45.5.2.1) over C . \square

Remark 45.5.4. In Situation 45.5.1 we denote $\text{Cris}^\wedge(C/A)$ the category whose objects are pairs $(B \rightarrow C, \delta)$ such that

- (1) B is a p -adically complete A -algebra,
- (2) $B \rightarrow C$ is a surjection of A -algebras,
- (3) δ is a divided power structure on $\text{Ker}(B \rightarrow C)$,
- (4) $A \rightarrow B$ is a homomorphism of divided power rings.

Morphisms are defined as in Definition 45.5.2. Then $\text{Cris}(C/A) \subset \text{Cris}^\wedge(C/A)$ is the full subcategory consisting of those B such that p is nilpotent in B . Conversely, any object $(B \rightarrow C, \delta)$ of $\text{Cris}^\wedge(C/A)$ is equal to the limit

$$(B \rightarrow C, \delta) = \lim_e (B/p^e B \rightarrow C, \delta)$$

where for $e \gg 0$ the object $(B/p^e B \rightarrow C, \delta)$ lies in $\text{Cris}(C/A)$, see Divided Power Algebra, Lemma 23.4.5. In particular, we see that $\text{Cris}^\wedge(C/A)$ is a full subcategory of the category of pro-objects of $\text{Cris}(C/A)$, see Categories, Remark 4.22.4.

Lemma 45.5.5. *In Situation 45.5.1. Let $P \rightarrow C$ be a surjection of A -algebras with kernel J . Write $D_{P,\gamma}(J) = (D, \bar{J}, \bar{\gamma})$. Let $(D^\wedge, J^\wedge, \bar{\gamma}^\wedge)$ be the p -adic completion of D , see Divided Power Algebra, Lemma 23.4.5. For every $e \geq 1$ set $P_e = P/p^e P$ and $J_e \subset P_e$ the image of J and write $D_{P_e,\gamma}(J_e) = (D_e, \bar{J}_e, \bar{\gamma})$. Then for all e large enough we have*

- (1) $p^e D \subset \bar{J}$ and $p^e D^\wedge \subset \bar{J}^\wedge$ are preserved by divided powers,
- (2) $D^\wedge/p^e D^\wedge = D/p^e D = D_e$ as divided power rings,
- (3) $(D_e, \bar{J}_e, \bar{\gamma})$ is an object of $\text{Cris}(C/A)$,
- (4) $(D^\wedge, \bar{J}^\wedge, \bar{\gamma}^\wedge)$ is equal to $\lim_e (D_e, \bar{J}_e, \bar{\gamma})$, and
- (5) $(D^\wedge, \bar{J}^\wedge, \bar{\gamma}^\wedge)$ is an object of $\text{Cris}^\wedge(C/A)$.

Proof. Part (1) follows from Divided Power Algebra, Lemma 23.4.5. It is a general property of p -adic completion that $D/p^e D = D^\wedge/p^e D^\wedge$. Since $D/p^e D$ is a divided power ring and since $P \rightarrow D/p^e D$ factors through P_e , the universal property of D_e produces a map $D_e \rightarrow D/p^e D$. Conversely, the universal property of D produces a map $D \rightarrow D_e$ which factors through $D/p^e D$. We omit the verification that these maps are mutually inverse. This proves (2). If e is large enough, then $p^e C = 0$, hence we see (3) holds. Part (4) follows from Divided Power Algebra, Lemma 23.4.5. Part (5) is clear from the definitions. \square

Lemma 45.5.6. *In Situation 45.5.1. Let P be a polynomial algebra over A and let $P \rightarrow C$ be a surjection of A -algebras with kernel J . With $(D_e, \bar{J}_e, \bar{\gamma})$ as in Lemma 45.5.5: for every object (B, J_B, δ) of $\text{CRIS}(C/A)$ there exists an e and a morphism $D_e \rightarrow B$ of $\text{CRIS}(C/A)$.*

Proof. We can find an A -algebra homomorphism $P \rightarrow B$ lifting the map $C \rightarrow B/J_B$. By our definition of $\text{CRIS}(C/A)$ we see that $p^e B = 0$ for some e hence $P \rightarrow B$ factors as $P \rightarrow P_e \rightarrow B$. By the universal property of the divided power envelope we conclude that $P_e \rightarrow B$ factors through D_e . \square

Lemma 45.5.7. *In Situation 45.5.1. Let P be a polynomial algebra over A and let $P \rightarrow C$ be a surjection of A -algebras with kernel J . Let $(D, \bar{J}, \bar{\gamma})$ be the p -adic completion of $D_{P,\gamma}(J)$. For every object $(B \rightarrow C, \delta)$ of $\text{Cris}^\wedge(C/A)$ there exists a morphism $D \rightarrow B$ of $\text{Cris}^\wedge(C/A)$.*

Proof. We can find an A -algebra homomorphism $P \rightarrow B$ compatible with maps to C . By our definition of $\text{Cris}(C/A)$ we see that $P \rightarrow B$ factors as $P \rightarrow D_{P,\gamma}(J) \rightarrow B$. As B is p -adically complete we can factor this map through D . \square

45.6. Module of differentials

In this section we develop a theory of modules of differentials for divided power rings.

Definition 45.6.1. Let A be a ring. Let (B, J, δ) be a divided power ring. Let $A \rightarrow B$ be a ring map. Let M be an B -module. A *divided power A -derivation* into M is a map $\theta : B \rightarrow M$ which is additive, annihilates the elements of A , satisfies the Leibniz rule $\theta(bb') = b\theta(b') + b'\theta(b)$ and satisfies

$$\theta(\gamma_n(x)) = \gamma_{n-1}(x)\theta(x)$$

for all $n \geq 1$ and all $x \in J$.

In the situation of the definition, just as in the case of usual derivations, there exists a *universal divided power A-derivation*

$$d_{B/A,\delta} : B \rightarrow \Omega_{B/A,\delta}$$

such that any divided power A-derivation $\theta : B \rightarrow M$ is equal to $\theta = \xi \circ d_{B/A,\delta}$ for some B-linear map $\Omega_{B/A,\delta} \rightarrow M$. If $(A, I, \gamma) \rightarrow (B, J, \delta)$ is a homomorphism of divided power rings, then we can forget the divided powers on A and consider the divided power derivations of B over A. Here are some basic properties of the divided power module of differentials.

Lemma 45.6.2. *Let A be a ring. Let (B, J, δ) be a divided power ring and A → B a ring map.*

- (1) *Consider B[x] with divided power ideal (JB[x], δ') where δ' is the extension of δ to B[x]. Then*

$$\Omega_{B[x]/A,\delta'} = \Omega_{B/A,\delta} \otimes_B B[x] \oplus B[x]dx.$$

- (2) *Consider B⟨x⟩ with divided power ideal (JB⟨x⟩ + B⟨x⟩₊, δ'). Then*

$$\Omega_{B\langle x \rangle/A,\delta'} = \Omega_{B/A,\delta} \otimes_B B\langle x \rangle \oplus B\langle x \rangle dx.$$

- (3) *Let K ⊂ J be an ideal preserved by δ_n for all n > 0. Set B' = B/K and denote δ' the induced divided power on J/K. Then Ω_{B'/A,δ'} is the quotient of Ω_{B/A,δ} ⊗_B B' by the B'-submodule generated by dk for k ∈ K.*

Proof. These are proved directly from the construction of Ω_{B/A,δ} as the free B-module on the elements db modulo the relations

- (1) d(b + b') = db + db', b, b' ∈ B,
- (2) da = 0, a ∈ A,
- (3) d(bb') = bdb' + b'db, b, b' ∈ B,
- (4) dδ_n(f) = δ_{n-1}(f)df, f ∈ J, n > 1.

Note that the last relation explains why we get “the same” answer for the divided power polynomial algebra and the usual polynomial algebra: in the first case x is an element of the divided power ideal and hence dx^[n] = x^[n-1]dx. □

Let (A, I, γ) be a divided power ring. In this setting the correct version of the powers of I is given by the divided powers

$$I^{[n]} = \text{ideal generate by } \gamma_{e_1}(x_1) \dots \gamma_{e_t}(x_t) \text{ with } \sum e_j \geq n \text{ and } x_j \in I.$$

Of course we have Iⁿ ⊂ I^[n]. Note that I^[1] = I. Sometimes we also set I^[0] = A.

Lemma 45.6.3. *Let (A, I, γ) → (B, J, δ) be a homomorphism of divided power rings. Let (B(1), J(1), δ(1)) be the coproduct of (B, J, δ) with itself over (A, I, γ), i.e., such that*

$$\begin{array}{ccc} (B, J, \delta) & \longrightarrow & (B(1), J(1), \delta(1)) \\ \uparrow & & \uparrow \\ (A, I, \gamma) & \longrightarrow & (B, J, \delta) \end{array}$$

is cocartesian. Denote K = Ker(B(1) → B). Then K ∩ J(1) ⊂ J(1) is preserved by the divided power structure and

$$\Omega_{B/A,\delta} = K / \left(K^2 + (K \cap J(1))^{[2]} \right)$$

canonically.

Proof. The fact that $K \cap J(1) \subset J(1)$ is preserved by the divided power structure follows from the fact that $B(1) \rightarrow B$ is a homomorphism of divided power rings.

Recall that K/K^2 has a canonical B -module structure. Denote $s_0, s_1 : B \rightarrow B(1)$ the two coprojections and consider the map $d : B \rightarrow K/K^2 + (K \cap J(1))^{[2]}$ given by $b \mapsto s_1(b) - s_0(b)$. It is clear that d is additive, annihilates A , and satisfies the Leibniz rule. We claim that d is an A -derivation. Let $x \in J$. Set $y = s_1(x)$ and $z = s_0(x)$. Denote δ the divided power structure on $J(1)$. We have to show that $\delta_n(y) - \delta_n(z) = \delta_{n-1}(y)(y - z)$ modulo $K^2 + (K \cap J(1))^{[2]}$ for $n \geq 1$. We will show this by induction on n . It is true for $n = 1$. Let $n > 1$ and that it holds for all smaller values. Note that

$$\delta_n(z - y) = \sum_{i=0}^n (-1)^{n-i} \delta_i(z) \delta_{n-i}(y)$$

is an element of $K^2 + (K \cap J(1))^{[2]}$. From this and induction we see that working modulo $K^2 + (K \cap J(1))^{[2]}$ we have

$$\begin{aligned} & \delta_n(y) - \delta_n(z) \\ &= \delta_n(y) + \sum_{i=0}^{n-1} (-1)^{n-i} \delta_i(z) \delta_{n-i}(y) \\ &= \delta_n(y) + (-1)^n \delta_n(y) + \sum_{i=1}^{n-1} (-1)^{n-i} (\delta_i(y) - \delta_{i-1}(y)(y - z)) \delta_{n-i}(y) \end{aligned}$$

Using that $\delta_i(y) \delta_{n-i}(y) = \binom{n}{i} \delta_n(y)$ and that $\delta_{i-1}(y) \delta_{n-i}(y) = \binom{n-1}{i} \delta_{n-1}(y)$ the reader easily verifies that this expression comes out to give $\delta_{n-1}(y)(y - z)$ as desired.

Let M be a B -module. Let $\theta : B \rightarrow M$ be a divided power A -derivation. Set $D = B \oplus M$ where M is an ideal of square zero. Define a divided power structure on $J \oplus M \subset D$ by setting $\delta_n(x + m) = \delta_n(x) + \delta_{n-1}(x)m$ for $n > 1$, see Lemma 45.3.1. There are two divided power algebra homomorphisms $B \rightarrow D$: the first is given by the inclusion and the second by the map $b \mapsto b + \theta(b)$. Hence we get a canonical homomorphism $B(1) \rightarrow D$ of divided power algebras over (A, I, γ) . This induces a map $K \rightarrow M$ which annihilates K^2 (as M is an ideal of square zero) and $(K \cap J(1))^{[2]}$ as $M^{[2]} = 0$. The composition $B \rightarrow K/K^2 + (K \cap J(1))^{[2]} \rightarrow M$ equals θ by construction. It follows that d is a universal divided power A -derivation and we win. \square

Remark 45.6.4. Let $A \rightarrow B$ be a ring map and let (J, δ) be a divided power structure on B . The universal module $\Omega_{B/A, \delta}$ comes with a little bit of extra structure, namely the B -submodule N of $\Omega_{B/A, \delta}$ generated by $d_{B/A, \delta}(J)$. In terms of the isomorphism given in Lemma 45.6.3 this corresponds to the image of $K \cap J(1)$ in $\Omega_{B/A, \delta}$. Consider the A -algebra $D = B \oplus \Omega_{B/A, \delta}^1$ with ideal $\bar{J} = J \oplus N$ and divided powers $\bar{\delta}$ as in the proof of the lemma. Then $(D, \bar{J}, \bar{\delta})$ is a divided power ring and the two maps $B \rightarrow D$ given by $b \mapsto b$ and $b \mapsto b + d_{B/A, \delta}(b)$ are homomorphisms of divided power rings over A . Moreover, N is the smallest submodule of $\Omega_{B/A, \delta}$ such that this is true.

Lemma 45.6.5. *In Situation 45.5.1. Let (B, J, δ) be an object of $\text{CRIS}(C/A)$. Let $(B(1), J(1), \delta(1))$ be the coproduct of (B, J, δ) with itself in $\text{CRIS}(C/A)$. Denote $K = \text{Ker}(B(1) \rightarrow B)$. Then $K \cap J(1) \subset J(1)$ is preserved by the divided power*

structure and

$$\Omega_{B/A,\delta} = K / \left(K^2 + (K \cap J(1))^{[2]} \right)$$

canonically.

Proof. Word for word the same as the proof of Lemma 45.6.3. The only point that has to be checked is that the divided power ring $D = B \oplus M$ is an object of $\text{CRIS}(C/A)$ and that the two maps $B \rightarrow C$ are morphisms of $\text{CRIS}(C/A)$. Since $D/(J \oplus M) = B/J$ we can use $C \rightarrow B/J$ to view D as an object of $\text{CRIS}(C/A)$ and the statement on morphisms is clear from the construction. \square

Lemma 45.6.6. *Let (A, I, γ) be a divided power ring. Let $A \rightarrow B$ be a ring map and let $IB \subset J \subset B$ be an ideal. Let $D_{B,\gamma}(J) = (D, \bar{J}, \bar{\gamma})$ be the divided power envelope. Then we have*

$$\Omega_{D/A,\bar{\gamma}} = \Omega_{B/A} \otimes_B D$$

Proof. We will prove this first when B is flat over A . In this case γ extends to a divided power structure γ' on IB , see Divided Power Algebra, Lemma 23.4.2. Hence $D = D_{B',\gamma'}(J)$ is equal to a quotient of the divided power ring (D', J', δ) where $D' = B\langle x_t \rangle$ and $J' = IB\langle x_t \rangle + B\langle x_t \rangle_+$ by the elements $x_t - f_t$ and $\delta_n(\sum r_t x_t - r_0)$, see Lemma 45.2.4 for notation and explanation. Write $d : D' \rightarrow \Omega_{D'/A,\delta}$ for the universal derivation. Note that

$$\Omega_{D'/A,\delta} = \Omega_{B/A} \otimes_B D' \oplus \bigoplus D' dx_t,$$

see Lemma 45.6.2. We conclude that $\Omega_{D/A,\bar{\gamma}}$ is the quotient of $\Omega_{D'/A,\delta} \otimes_{D'} D$ by the submodule generated by d applied to the generators of the kernel of $D' \rightarrow D$ listed above, see Lemma 45.6.2. Since $d(x_t - f_t) = -df_t + dx_t$ we see that we have $dx_t = df_t$ in the quotient. In particular we see that $\Omega_{B/A} \otimes_B D \rightarrow \Omega_{D/A,\bar{\gamma}}$ is surjective with kernel given by the images of d applied to the elements $\delta_n(\sum r_t x_t - r_0)$. However, given a relation $\sum r_t f_t - r_0 = 0$ in B with $r_t \in B$ and $r_0 \in IB$ we see that

$$\begin{aligned} d\delta_n(\sum r_t x_t - r_0) &= \delta_{n-1}(\sum r_t x_t - r_0)d(\sum r_t x_t - r_0) \\ &= \delta_{n-1}(\sum r_t x_t - r_0) \left(\sum r_t d(x_t - f_t) + \sum (x_t - f_t) dr_t \right) \end{aligned}$$

because $\sum r_t f_t - r_0 = 0$ in B . Hence this is already zero in $\Omega_{B/A} \otimes_A D$ and we win in the case that B is flat over A .

In the general case we write B as a quotient of a polynomial ring $P \rightarrow B$ and let $J' \subset P$ be the inverse image of J . Then $D = D'/K'$ with notation as in Lemma 45.2.3. By the case handled in the first paragraph of the proof we have $\Omega_{D'/A,\bar{\gamma}'} = \Omega_{P/A} \otimes_P D'$. Then $\Omega_{D/A,\bar{\gamma}}$ is the quotient of $\Omega_{P/A} \otimes_P D$ by the submodule generated by $d\bar{\gamma}'_n(k)$ where k is an element of the kernel of $P \rightarrow B$, see Lemma 45.6.2 and the description of K' from Lemma 45.2.3. Since $d\bar{\gamma}'_n(k) = \bar{\gamma}'_{n-1}(k)dk$ we see again that it suffices to divided by the submodule generated by dk with $k \in \text{Ker}(P \rightarrow B)$ and since $\Omega_{B/A}$ is the quotient of $\Omega_{P/A} \otimes_A B$ by these elements (Algebra, Lemma 10.127.9) we win. \square

Remark 45.6.7. Let B be a ring. Write $\Omega_B = \Omega_{B/\mathbf{Z}}$ for the absolute² module of differentials of B . Let $d : B \rightarrow \Omega_B$ denote the universal derivation. Set $\Omega_B^i = \wedge_B^i(\Omega_B)$ as in Algebra, Section 10.12. The absolute *de Rham complex*

$$\Omega_B^0 \rightarrow \Omega_B^1 \rightarrow \Omega_B^2 \rightarrow \dots$$

Here $d : \Omega_B^p \rightarrow \Omega_B^{p+1}$ is defined by the rule

$$d(b_0 db_1 \wedge \dots \wedge db_p) = db_0 \wedge db_1 \wedge \dots \wedge db_p$$

which we will show is well defined; note that $d \circ d = 0$ so we get a complex. Recall that Ω_B is the B -module generated by elements db subject to the relations $d(a+b) = da + db$ and $d(ab) = bda + adb$ for $a, b \in B$. To prove that our map is well defined for $p = 1$ we have to show that the elements

$$ad(b+c) - adb - adc \quad \text{and} \quad ad(bc) - acdb - abdc, \quad a, b, c \in B$$

are mapped to zero by our rule. This is clear by direct computation (using the Leibniz rule). Thus we get a map

$$\Omega_B \otimes_{\mathbf{Z}} \dots \otimes_{\mathbf{Z}} \Omega_B \longrightarrow \Omega_B^{p+1}$$

defined by the formula

$$\omega_1 \otimes \dots \otimes \omega_p \longmapsto \sum (-1)^{i+1} \omega_1 \wedge \dots \wedge d(\omega_i) \wedge \dots \wedge \omega_p$$

which matches our rule above on elements of the form $b_0 db_1 \otimes db_2 \otimes \dots \otimes db_p$. It is clear that this map is alternating. To finish we have to show that

$$\omega_1 \otimes \dots \otimes f\omega_i \otimes \dots \otimes \omega_p \quad \text{and} \quad \omega_1 \otimes \dots \otimes f\omega_j \otimes \dots \otimes \omega_p$$

are mapped to the same element. By \mathbf{Z} -linearity and the alternating property, it is enough to show this for $p = 2$, $i = 1$, $j = 2$, $\omega_1 = a_1 db_1$ and $\omega_2 = a_2 db_2$. Thus we need to show that

$$\begin{aligned} & dfa_1 \wedge db_1 \wedge a_2 db_2 - fa_1 db_1 \wedge da_2 \wedge db_2 \\ &= da_1 \wedge db_1 \wedge fa_2 db_2 - a_1 db_1 \wedge dfa_2 \wedge db_2 \end{aligned}$$

in other words that

$$(a_2 dfa_1 + fa_1 da_2 - fa_2 da_1 - a_1 dfa_2) \wedge db_1 \wedge db_2 = 0.$$

This follows from the Leibniz rule.

Lemma 45.6.8. *Let B be a ring. Let $\pi : \Omega_B \rightarrow \Omega$ be a surjective B -module map. Denote $d : B \rightarrow \Omega$ the composition of π with $d_B : B \rightarrow \Omega_B$. Set $\Omega^i = \wedge_B^i(\Omega)$. Assume that the kernel of π is generated, as a B -module, by elements $\omega \in \Omega_B$ such that $d_B(\omega) \in \Omega_B^2$ maps to zero in Ω^2 . Then there is a de Rham complex*

$$\Omega^0 \rightarrow \Omega^1 \rightarrow \Omega^2 \rightarrow \dots$$

whose differential is defined by the rule

$$d : \Omega^p \rightarrow \Omega^{p+1}, \quad d(f_0 df_1 \wedge \dots \wedge df_p) = df_0 \wedge df_1 \wedge \dots \wedge df_p$$

²This actually makes sense: if Ω_B is the module of differentials where we only assume the Leibniz rule and not the vanishing of $d1$, then the Leibniz rule gives $d1 = d(1 \cdot 1) = 1d1 + 1d1 = 2d1$ and hence $d1 = 0$ in Ω_B .

Proof. We will show that there exists a commutative diagram

$$\begin{array}{ccccccc}
 \Omega_B^0 & \xrightarrow{d_B} & \Omega_B^1 & \xrightarrow{d_B} & \Omega_B^2 & \xrightarrow{d_B} & \dots \\
 \downarrow & & \downarrow \pi & & \downarrow \wedge^2 \pi & & \\
 \Omega^0 & \xrightarrow{d} & \Omega^1 & \xrightarrow{d} & \Omega^2 & \xrightarrow{d} & \dots
 \end{array}$$

the description of the map d will follow from the construction of d_B in Remark 45.6.7. Since the left most vertical arrow is an isomorphism we have the first square. Because π is surjective, to get the second square it suffices to show that d_B maps the kernel of π into the kernel of $\wedge^2 \pi$. We are given that any element of the kernel of π is of the form $\sum b_i \omega_i$ with $\pi(\omega_i) = 0$ and $\wedge^2 \pi(d_B(\omega_i)) = 0$. By the Leibniz rule for d_B we have $d_B(\sum b_i \omega_i) = \sum b_i d_B(\omega_i) + \sum d_B(b_i) \wedge \omega_i$. Hence this maps to zero under $\wedge^2 \pi$.

For $i > 1$ we note that $\wedge^i \pi$ is surjective with kernel the image of $\text{Ker}(\pi) \wedge \Omega_B^{i-1} \rightarrow \Omega_B^i$. For $\omega_1 \in \text{Ker}(\pi)$ and $\omega_2 \in \Omega_B^{i-1}$ we have

$$d_B(\omega_1 \wedge \omega_2) = d_B(\omega_1) \wedge \omega_2 - \omega_1 \wedge d_B(\omega_2)$$

which is in the kernel of $\wedge^{i+1} \pi$ by what we just proved above. Hence we get the $(i + 1)$ st square in the diagram above. This concludes the proof. \square

Remark 45.6.9. Let $A \rightarrow B$ be a ring map and let (J, δ) be a divided power structure on B . Set $\Omega_{B/A, \delta}^i = \wedge_B^i \Omega_{B/A, \delta}$ where $\Omega_{B/A, \delta}$ is the target of the universal divided power A -derivation $d = d_{B/A} : B \rightarrow \Omega_{B/A, \delta}$. Note that $\Omega_{B/A, \delta}$ is the quotient of Ω_B by the B -submodule generated by the elements $da = 0$ for $a \in A$ and $d\delta_n(x) - \delta_{n-1}(x)dx$ for $x \in J$. We claim Lemma 45.6.8 applies. To see this it suffices to verify the elements da and $d\delta_n(x) - \delta_{n-1}(x)dx$ of Ω_B are mapped to zero in $\Omega_{B/A, \delta}^2$. This is clear for the first, and for the last we observe that

$$d(\delta_{n-1}(x)) \wedge dx = \delta_{n-2}(x)dx \wedge dx = 0$$

in $\Omega_{B/A, \delta}^2$ as desired. Hence we obtain a *divided power de Rham complex*

$$\Omega_{B/A, \delta}^0 \rightarrow \Omega_{B/A, \delta}^1 \rightarrow \Omega_{B/A, \delta}^2 \rightarrow \dots$$

which will play an important role in the sequel.

Remark 45.6.10. Let B be a ring. Let $\Omega_B \rightarrow \Omega$ be a quotient satisfying the assumptions of Lemma 45.6.8. Let M be a B -module. A *connection* is an additive map

$$\nabla : M \rightarrow M \otimes_B \Omega$$

such that $\nabla(bm) = b\nabla(m) + m \otimes db$ for $b \in B$ and $m \in M$. In this situation we can define maps

$$\nabla : M \otimes_B \Omega^i \rightarrow M \otimes_B \Omega^{i+1}$$

by the rule $\nabla(m \otimes \omega) = \nabla(m) \wedge \omega + m \otimes d\omega$. This works because if $b \in B$, then

$$\begin{aligned}
 \nabla(bm \otimes \omega) - \nabla(m \otimes b\omega) &= \nabla(bm) \otimes \omega + bm \otimes d\omega - \nabla(m) \otimes b\omega - m \otimes d(b\omega) \\
 &= b\nabla(m) \otimes \omega + m \otimes db \wedge \omega + bm \otimes d\omega \\
 &\quad - b\nabla(m) \otimes \omega - bm \otimes d(\omega) - m \otimes db \wedge \omega = 0
 \end{aligned}$$

As is customary we say the connection is *integrable* if and only if the composition

$$M \xrightarrow{\nabla} M \otimes_B \Omega^1 \xrightarrow{\nabla} M \otimes_B \Omega^2$$

is zero. In this case we obtain a complex

$$M \xrightarrow{\nabla} M \otimes_B \Omega^1 \xrightarrow{\nabla} M \otimes_B \Omega^2 \xrightarrow{\nabla} M \otimes_B \Omega^3 \xrightarrow{\nabla} M \otimes_B \Omega^4 \rightarrow \dots$$

which is called the de Rham complex of the connection.

Remark 45.6.11. Let $\varphi : B \rightarrow B'$ be a ring map. Let $\Omega_B \rightarrow \Omega$ and $\Omega_{B'} \rightarrow \Omega'$ be quotients satisfying the assumptions of Lemma 45.6.8. Assume that the map $\Omega_B \rightarrow \Omega_{B'}$, $b_1 db_2 \mapsto \varphi(b_1) d\varphi(b_2)$ fits into a commutative diagram

$$\begin{array}{ccccc} B & \longrightarrow & \Omega_B & \longrightarrow & \Omega \\ \downarrow & & \downarrow & & \downarrow \varphi \\ B' & \longrightarrow & \Omega_{B'} & \longrightarrow & \Omega' \end{array}$$

In this situation, given any pair (M, ∇) where M is a B -module and $\nabla : M \rightarrow M \otimes_B \Omega$ is a connection we obtain a *base change* $(M \otimes_B B', \nabla')$ where

$$\nabla' : M \otimes_B B' \longrightarrow (M \otimes_B B') \otimes_{B'} \Omega' = M \otimes_B \Omega'$$

is defined by the rule

$$\nabla'(m \otimes b') = \sum m_i \otimes b' d\varphi(b_i) + m \otimes db'$$

if $\nabla(m) = \sum m_i \otimes db_i$. If ∇ is integrable, then so is ∇' , and in this case there is a canonical map of de Rham complexes

$$(45.6.11.1) \quad M \otimes_B \Omega^\bullet \longrightarrow (M \otimes_B B') \otimes_{B'} (\Omega')^\bullet = M \otimes_B (\Omega')^\bullet$$

which maps $m \otimes \eta$ to $m \otimes \varphi(\eta)$.

Lemma 45.6.12. Let $A \rightarrow B$ be a ring map and let (J, δ) be a divided power structure on B . Let p be a prime number. Assume that A is a $\mathbf{Z}_{(p)}$ -algebra and that p is nilpotent in B/J . Then we have

$$\lim_e \Omega_{B_e/A, \bar{\delta}} = \lim_e \Omega_{B/A, \delta} / p^e \Omega_{B/A, \delta} = \lim_e \Omega_{B^\wedge/A, \delta^\wedge} / p^e \Omega_{B^\wedge/A, \delta^\wedge}$$

see proof for notation and explanation.

Proof. By Divided Power Algebra, Lemma 23.4.5 we see that δ extends to $B_e = B/p^e B$ for all sufficiently large e . Hence the first limit make sense. The lemma also produces a divided power structure δ^\wedge on the completion $B^\wedge = \lim_e B_e$, hence the last limit makes sense. By Lemma 45.6.2 and the fact that $dp^e = 0$ (always) we see that the surjection $\Omega_{B/A, \delta} \rightarrow \Omega_{B_e/A, \bar{\delta}}$ has kernel $p^e \Omega_{B/A, \delta}$. Similarly for the kernel of $\Omega_{B^\wedge/A, \delta^\wedge} \rightarrow \Omega_{B_e/A, \bar{\delta}}$. Hence the lemma is clear. \square

45.7. Divided power schemes

Some remarks on how to globalize the previous notions.

Definition 45.7.1. Let \mathcal{C} be a site. Let \mathcal{O} be a sheaf of rings on \mathcal{C} . Let $\mathcal{I} \subset \mathcal{O}$ be a sheaf of ideals. A *divided power structure* γ on \mathcal{I} is a sequence of maps $\gamma_n : \mathcal{I} \rightarrow \mathcal{I}$, $n \geq 1$ such that for any object U of \mathcal{C} the triple

$$(\mathcal{O}(U), \mathcal{I}(U), \gamma)$$

is a divided power ring.

To be sure this applies in particular to sheaves of rings on topological spaces. But it's good to be a little bit more general as the structure sheaf of the crystalline site lives on a... site! A triple $(\mathcal{C}, \mathcal{I}, \gamma)$ as in the definition above is sometimes called a *divided power topos* in this chapter. Given a second $(\mathcal{C}', \mathcal{I}', \gamma')$ and given a morphism of ringed topoi $(f, f^\#) : (\mathit{Sh}(\mathcal{C}), \mathcal{O}) \rightarrow (\mathit{Sh}(\mathcal{C}'), \mathcal{O}')$ we say that $(f, f^\#)$ induces a *morphism of divided power topoi* if $f^\#(f^{-1}\mathcal{I}') \subset \mathcal{I}$ and the diagrams

$$\begin{array}{ccc} f^{-1}\mathcal{I}' & \xrightarrow{\quad} & \mathcal{I} \\ f^{-1}\gamma'_n \downarrow & & \downarrow \gamma_n \\ f^{-1}\mathcal{I}' & \xrightarrow{f^\#} & \mathcal{I} \end{array}$$

are commutative for all $n \geq 1$. If f comes from a morphism of sites induced by a functor $u : \mathcal{C}' \rightarrow \mathcal{C}$ then this just means that

$$(\mathcal{O}'(U'), \mathcal{I}'(U'), \gamma') \longrightarrow (\mathcal{O}(u(U')), \mathcal{I}(u(U')), \gamma)$$

is a homomorphism of divided power rings for all $U' \in \text{Ob}(\mathcal{C}')$.

In the case of schemes we require the divided power ideal to be **quasi-coherent**. But apart from this the definition is exactly the same as in the case of topoi. Here it is.

Definition 45.7.2. A *divided power scheme* is a triple (S, \mathcal{I}, γ) where S is a scheme, \mathcal{I} is a quasi-coherent sheaf of ideals, and γ is a divided power structure on \mathcal{I} . A *morphism of divided power schemes* $(S, \mathcal{I}, \gamma) \rightarrow (S', \mathcal{I}', \gamma')$ is a morphism of schemes $f : S \rightarrow S'$ such that $f^{-1}\mathcal{I}'\mathcal{O}_S \subset \mathcal{I}$ and such that

$$(\mathcal{O}_S(U'), \mathcal{I}(U'), \gamma) \longrightarrow (\mathcal{O}_{S'}(f^{-1}U'), \mathcal{I}(f^{-1}U'), \gamma)$$

is a homomorphism of divided power rings for all $U' \subset S'$ open.

Recall that there is a 1-to-1 correspondence between quasi-coherent sheaves of ideals and closed immersions, see Morphisms, Section 28.2. Thus given a divided power scheme (T, \mathcal{J}, γ) we get a canonical closed immersion $U \rightarrow T$ defined by \mathcal{J} . Conversely, given a closed immersion $U \rightarrow T$ and a divided power structure γ on the sheaf of ideals \mathcal{J} associated to $U \rightarrow T$ we obtain a divided power scheme (T, \mathcal{J}, γ) . In many situations we only want to consider such triples (U, T, γ) when the morphism $U \rightarrow T$ is a thickening, see More on Morphisms, Definition 36.2.1.

Definition 45.7.3. A triple (U, T, γ) as above is called a *divided power thickening* if $U \rightarrow T$ is a thickening.

Fibre products of divided power schemes exist when one of the three is a divided power thickening. Here is a formal statement.

Lemma 45.7.4. *Let $(U', T', \delta') \rightarrow (S'_0, S', \gamma')$ and $(S_0, S, \gamma) \rightarrow (S'_0, S', \gamma')$ be morphisms of divided power schemes. If (U', T', δ') is a divided power thickening, then there exists a divided power scheme (T_0, T, δ) and*

$$\begin{array}{ccc} T & \longrightarrow & T' \\ \downarrow & & \downarrow \\ S & \longrightarrow & S' \end{array}$$

which is a cartesian diagram in the category of divided power schemes.

Proof. Omitted. Hints: If T exists, then $T_0 = S_0 \times_{S'_0} U'$ (argue as in Divided Power Algebra, Remark 23.3.5). Since T' is a divided power thickening, we see that T (if it exists) will be a divided power thickening too. Hence we can define T as the scheme with underlying topological space the underlying topological space of $T_0 = S_0 \times_{S'_0} U'$ and as structure sheaf on affine pieces the ring given by Lemma 45.5.3. \square

We make the following observation. Suppose that (U, T, γ) is triple as above. Assume that T is a scheme over $\mathbf{Z}_{(p)}$ and that p is locally nilpotent on U . Then

- (1) p locally nilpotent on $T \Leftrightarrow U \rightarrow T$ is a thickening (see Divided Power Algebra, Lemma 23.2.6), and
- (2) $p^e \mathcal{O}_T$ is locally on T preserved by γ for $e \gg 0$ (see Divided Power Algebra, Lemma 23.4.5).

This suggest that good results on divided power thickenings will be available under the following hypotheses.

Situation 45.7.5. Here p is a prime number and (S, \mathcal{I}, γ) is a divided power scheme over $\mathbf{Z}_{(p)}$. We set $S_0 = V(\mathcal{I}) \subset S$. Finally, $X \rightarrow S_0$ is a morphism of schemes such that p is locally nilpotent on X .

It is in this situation that we will define the big and small crystalline sites.

45.8. The big crystalline site

We first define the big site. Given a divided power scheme (S, \mathcal{I}, γ) we say (T, \mathcal{J}, δ) is a divided power scheme over (S, \mathcal{I}, γ) if T comes endowed with a morphism $T \rightarrow S$ of divided power schemes. Similarly, we say a divided power thickening (U, T, δ) is a divided power thickening over (S, \mathcal{I}, γ) if T comes endowed with a morphism $T \rightarrow S$ of divided power schemes.

Definition 45.8.1. In Situation 45.7.5.

- (1) A *divided power thickening of X relative to (S, \mathcal{I}, γ)* is given by a divided power thickening (U, T, δ) over (S, \mathcal{I}, γ) and an S -morphism $U \rightarrow X$.
- (2) A *morphism of divided power thickenings of X relative to (S, \mathcal{I}, γ)* is defined in the obvious manner.

The category of divided power thickenings of X relative to (S, \mathcal{I}, γ) is denoted $\text{CRIS}(X/S, \mathcal{I}, \gamma)$ or simply $\text{CRIS}(X/S)$.

For any (U, T, δ) in $\text{CRIS}(X/S)$ we have that p is locally nilpotent on T , see discussion after Definition 45.7.3. A good way to visualize all the data associated to (U, T, δ) is the commutative diagram

$$\begin{array}{ccc}
 T & \longleftarrow & U \\
 \downarrow & & \downarrow \\
 & & X \\
 \downarrow & & \downarrow \\
 S & \longleftarrow & S_0
 \end{array}$$

where $S_0 = V(\mathcal{I}) \subset S$. Morphisms of $\text{CRIS}(X/S)$ can be similarly visualized as huge commutative diagrams. In particular, there is a canonical forgetful functor

$$(45.8.1.1) \quad \text{CRIS}(X/S) \longrightarrow \text{Sch}/X, \quad (U, T, \delta) \longmapsto U$$

as well as its one sided inverse (and left adjoint)

$$(45.8.1.2) \quad \text{Sch}/X \longrightarrow \text{CRIS}(X/S), \quad U \longmapsto (U, U, \emptyset)$$

which is sometimes useful.

Lemma 45.8.2. *In Situation 45.7.5. The category $\text{CRIS}(X/S)$ has all finite nonempty limits, in particular products of pairs and fibre products. The functor (45.8.1.1) commutes with limits.*

Proof. Omitted. Hint: See Lemma 45.5.3 for the affine case. See also Divided Power Algebra, Remark 23.3.5. \square

Lemma 45.8.3. *In Situation 45.7.5. Let*

$$\begin{array}{ccc} (U_3, T_3, \delta_3) & \longrightarrow & (U_2, T_2, \delta_2) \\ \downarrow & & \downarrow \\ (U_1, T_1, \delta_1) & \longrightarrow & (U, T, \delta) \end{array}$$

be a fibre square in the category of divided power thickenings of X relative to (S, \mathcal{I}, γ) . If $T_2 \rightarrow T$ is flat, then $T_3 = T_1 \times_T T_2$ (as schemes).

Proof. This is true because a divided power structure extends uniquely along a flat ring map. See Divided Power Algebra, Lemma 23.4.2. \square

The lemma above means that the base change of a flat morphism of divided power thickenings is another flat morphism, and in fact is the “usual” base change of the morphism. This implies that the following definition makes sense.

Definition 45.8.4. In Situation 45.7.5.

- (1) A family of morphisms $\{(U_i, T_i, \delta_i) \rightarrow (U, T, \delta)\}$ of divided power thickenings of X/S is a *Zariski, étale, smooth, syntomic, or fppf covering* if and only if the family of morphisms of schemes $\{T_i \rightarrow T\}$ is one.
- (2) The *big crystalline site* of X over (S, \mathcal{I}, γ) , is the category $\text{CRIS}(X/S)$ endowed with the Zariski topology.
- (3) The topos of sheaves on $\text{CRIS}(X/S)$ is denoted $(X/S)_{\text{CRIS}}$ or sometimes $(X/S, \mathcal{I}, \gamma)_{\text{CRIS}}$ ³.

There are some obvious functorialities concerning these topoi.

Remark 45.8.5 (Functoriality). Let p be a prime number. Let $(S, \mathcal{I}, \gamma) \rightarrow (S', \mathcal{I}', \gamma')$ be a morphism of divided power schemes over $\mathbf{Z}_{(p)}$. Set $S_0 = V(\mathcal{I})$ and $S'_0 = V(\mathcal{I}')$. Let

$$\begin{array}{ccc} X & \xrightarrow{\quad} & Y \\ \downarrow & & \downarrow \\ S_0 & \longrightarrow & S'_0 \end{array}$$

³This clashes with our convention to denote the topos associated to a site \mathcal{C} by $Sh(\mathcal{C})$.

be a commutative diagram of morphisms of schemes and assume p is locally nilpotent on X and Y . Then we get a continuous and cocontinuous functor

$$\text{CRIS}(X/S) \longrightarrow \text{CRIS}(Y/S')$$

by letting (U, T, δ) correspond to (U, T, δ) with $U \rightarrow X \rightarrow Y$ as the S' -morphism from U to Y . Hence we get a morphism of topoi

$$f_{\text{CRIS}} : (X/S)_{\text{CRIS}} \longrightarrow (Y/S')_{\text{CRIS}}$$

see Sites, Section 7.20.

Remark 45.8.6 (Comparison with Zariski site). In Situation 45.7.5. The functor (45.8.1.1) is continuous, cocontinuous, and commutes with products and fibred products. Hence we obtain a morphism of topoi

$$U_{X/S} : (X/S)_{\text{CRIS}} \longrightarrow \text{Sh}((\text{Sch}/X)_{\text{Zar}})$$

from the big crystalline topos of X/S to the big Zariski topos of X . See Sites, Section 7.20.

Remark 45.8.7 (Structure morphism). In Situation 45.7.5. Consider the closed subscheme $S_0 = V(\mathcal{I}) \subset S$. If we assume that p is locally nilpotent on S_0 (which is always the case in practice) then we obtain a situation as in Definition 45.8.1 with S_0 instead of X . Hence we get a site $\text{CRIS}(S_0/S)$. If $f : X \rightarrow S_0$ is the structure morphism of X over S , then we get a commutative diagram of morphisms of ringed topoi

$$\begin{array}{ccc} (X/S)_{\text{CRIS}} & \xrightarrow{f_{\text{CRIS}}} & (S_0/S)_{\text{CRIS}} \\ U_{X/S} \downarrow & & \downarrow U_{S_0/S} \\ \text{Sh}((\text{Sch}/X)_{\text{Zar}}) & \xrightarrow{f_{\text{big}}} & \text{Sh}((\text{Sch}/S_0)_{\text{Zar}}) \\ & & \searrow \\ & & \text{Sh}((\text{Sch}/S)_{\text{Zar}}) \end{array}$$

by Remark 45.8.5. We think of the composition $(X/S)_{\text{CRIS}} \rightarrow \text{Sh}((\text{Sch}/S)_{\text{Zar}})$ as the structure morphism of the big crystalline site. Even if p is not locally nilpotent on S_0 the structure morphism

$$(X/S)_{\text{CRIS}} \longrightarrow \text{Sh}((\text{Sch}/S)_{\text{Zar}})$$

is defined as we can take the lower route through the diagram above. Thus it is the morphism of topoi corresponding to the cocontinuous functor $\text{CRIS}(X/S) \rightarrow (\text{Sch}/S)_{\text{Zar}}$ given by the rule $(U, T, \delta)/S \mapsto T/S$, see Sites, Section 7.20.

Remark 45.8.8 (Compatibilities). The morphisms defined above satisfy numerous compatibilities. For example, in the situation of Remark 45.8.5 we obtain a commutative diagram of ringed topoi

$$\begin{array}{ccc} (X/S)_{\text{CRIS}} & \longrightarrow & (Y/S')_{\text{CRIS}} \\ \downarrow & & \downarrow \\ \text{Sh}((\text{Sch}/S)_{\text{Zar}}) & \longrightarrow & \text{Sh}((\text{Sch}/S')_{\text{Zar}}) \end{array}$$

where the vertical arrows are the structure morphisms.

45.9. The crystalline site

Since (45.8.1.1) commutes with products and fibre products, we see that looking at those (U, T, δ) such that $U \rightarrow X$ is an open immersion defines a full subcategory preserved under fibre products (and more generally finite nonempty limits). Hence the following definition makes sense.

Definition 45.9.1. In Situation 45.7.5.

- (1) The (small) *crystalline site* of X over (S, \mathcal{I}, γ) , denoted $\text{Cris}(X/S, \mathcal{I}, \gamma)$ or simply $\text{Cris}(X/S)$ is the full subcategory of $\text{CRIS}(X/S)$ consisting of those (U, T, δ) in $\text{CRIS}(X/S)$ such that $U \rightarrow X$ is an open immersion. It comes endowed with the Zariski topology.
- (2) The topos of sheaves on $\text{Cris}(X/S)$ is denoted $(X/S)_{\text{cris}}$ or sometimes $(X/S, \mathcal{I}, \gamma)_{\text{cris}}$ ⁴.

For any (U, T, δ) in $\text{Cris}(X/S)$ the morphism $U \rightarrow X$ defines an object of the small Zariski site X_{Zar} of X . Hence a canonical forgetful functor

$$(45.9.1.1) \quad \text{Cris}(X/S) \longrightarrow X_{\text{Zar}}, \quad (U, T, \delta) \longmapsto U$$

and a left adjoint

$$(45.9.1.2) \quad X_{\text{Zar}} \longrightarrow \text{Cris}(X/S), \quad U \longmapsto (U, U, \emptyset)$$

which is sometimes useful.

We can compare the small and big crystalline sites, just like we can compare the small and big Zariski sites of a scheme, see Topologies, Lemma 33.3.13.

Lemma 45.9.2. *Assumptions as in Definition 45.8.1. The inclusion functor*

$$\text{Cris}(X/S) \rightarrow \text{CRIS}(X/S)$$

commutes with finite nonempty limits, is fully faithful, continuous, and cocontinuous. There are morphisms of topoi

$$(X/S)_{\text{cris}} \xrightarrow{i} (X/S)_{\text{CRIS}} \xrightarrow{\pi} (X/S)_{\text{cris}}$$

whose composition is the identity and of which the first is induced by the inclusion functor. Moreover, $\pi_ = i^{-1}$.*

Proof. For the first assertion see Lemma 45.8.2. This gives us a morphism of topoi $i : (X/S)_{\text{cris}} \rightarrow (X/S)_{\text{CRIS}}$ and a left adjoint $i_!$ such that $i^{-1}i_! = i^{-1}i_* = \text{id}$, see Sites, Lemmas 7.20.5, 7.20.6, and 7.20.7. We claim that $i_!$ is exact. If this is true, then we can define π by the rules $\pi^{-1} = i_!$ and $\pi_* = i^{-1}$ and everything is clear. To prove the claim, note that we already know that $i_!$ is right exact and preserves fibre products (see references given). Hence it suffices to show that $i_! * = *$ where $*$ indicates the final object in the category of sheaves of sets. To see this it suffices to produce a set of objects (U_i, T_i, δ_i) , $i \in I$ of $\text{Cris}(X/S)$ such that

$$\coprod_{i \in I} h_{(U_i, T_i, \delta_i)} \rightarrow *$$

is surjective in $(X/S)_{\text{CRIS}}$ (details omitted; hint: use that $\text{Cris}(X/S)$ has products and that the functor $\text{Cris}(X/S) \rightarrow \text{CRIS}(X/S)$ commutes with them). In the affine case this follows from Lemma 45.5.6. We omit the proof in general. \square

⁴This clashes with our convention to denote the topos associated to a site \mathcal{C} by $Sh(\mathcal{C})$.

Remark 45.9.3 (Functoriality). Let p be a prime number. Let $(S, \mathcal{I}, \gamma) \rightarrow (S', \mathcal{I}', \gamma')$ be a morphism of divided power schemes over $\mathbf{Z}_{(p)}$. Let

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow & & \downarrow \\ S_0 & \longrightarrow & S'_0 \end{array}$$

be a commutative diagram of morphisms of schemes and assume p is locally nilpotent on X and Y . By analogy with Topologies, Lemma 33.3.16 we define

$$f_{\text{cris}} : (X/S)_{\text{cris}} \longrightarrow (Y/S')_{\text{cris}}$$

by the formula $f_{\text{cris}} = \pi_Y \circ f_{\text{CRIS}} \circ i_X$ where i_X and π_Y are as in Lemma 45.9.2 for X and Y and where f_{CRIS} is as in Remark 45.8.5.

Remark 45.9.4 (Comparison with Zariski site). In Situation 45.7.5. The functor (45.9.1.1) is continuous, cocontinuous, and commutes with products and fibred products. Hence we obtain a morphism of topoi

$$u_{X/S} : (X/S)_{\text{cris}} \longrightarrow \text{Sh}(X_{\text{Zar}})$$

relating the small crystalline topoi of X/S with the small Zariski topoi of X . See Sites, Section 7.20.

Lemma 45.9.5. *In Situation 45.7.5. Let $X' \subset X$ and $S' \subset S$ be open subschemes such that X' maps into S' . Then there is a fully faithful functor $\text{Cris}(X'/S') \rightarrow \text{Cris}(X/S)$ which gives rise to a morphism of topoi fitting into the commutative diagram*

$$\begin{array}{ccc} (X'/S')_{\text{cris}} & \longrightarrow & (X/S)_{\text{cris}} \\ u_{X'/S'} \downarrow & & \downarrow u_{X/S} \\ \text{Sh}(X'_{\text{Zar}}) & \longrightarrow & \text{Sh}(X_{\text{Zar}}) \end{array}$$

Moreover, this diagram is an example of localization of morphisms of topoi as in Sites, Lemma 7.30.1.

Proof. The fully faithful functor comes from thinking of objects of $\text{Cris}(X'/S')$ as divided power thickenings (U, T, δ) of X' where $U \rightarrow X'$ factors through $X' \subset X$ (since then automatically $T \rightarrow S'$ will factor through S'). This functor is clearly cocontinuous hence we obtain a morphism of topoi as indicated. Let $h_{X'} \in \text{Sh}(X_{\text{Zar}})$ be the representable sheaf associated to X' viewed as an object of X_{Zar} . It is clear that $\text{Sh}(X'_{\text{Zar}})$ is the localization $\text{Sh}(X_{\text{Zar}})/h_{X'}$. On the other hand, the category $\text{Cris}(X/S)/u_{X/S}^{-1}h_{X'}$ (see Sites, Lemma 7.29.3) is canonically identified with $\text{Cris}(X'/S')$ by the functor above. This finishes the proof. \square

Remark 45.9.6 (Structure morphism). In Situation 45.7.5. Consider the closed subscheme $S_0 = V(\mathcal{I}) \subset S$. If we assume that p is locally nilpotent on S_0 (which is always the case in practice) then we obtain a situation as in Definition 45.8.1 with S_0 instead of X . Hence we get a site $\text{Cris}(S_0/S)$. If $f : X \rightarrow S_0$ is the structure

morphism of X over S , then we get a commutative diagram of ringed topoi

$$\begin{array}{ccc}
 (X/S)_{\text{cris}} & \xrightarrow{f_{\text{cris}}} & (S_0/S)_{\text{cris}} \\
 u_{X/S} \downarrow & & \downarrow u_{S_0/S} \\
 \text{Sh}(X_{Zar}) & \xrightarrow{f_{\text{small}}} & \text{Sh}(S_{0,Zar}) \\
 & & \searrow \\
 & & \text{Sh}(S_{Zar})
 \end{array}$$

see Remark 45.9.3. We think of the composition $(X/S)_{\text{cris}} \rightarrow \text{Sh}(S_{Zar})$ as the structure morphism of the crystalline site. Even if p is not locally nilpotent on S_0 the structure morphism

$$\tau_{X/S} : (X/S)_{\text{cris}} \longrightarrow \text{Sh}(S_{Zar})$$

is defined as we can take the lower route through the diagram above.

Remark 45.9.7 (Compatibilities). The morphisms defined above satisfy numerous compatibilities. For example, in the situation of Remark 45.9.3 we obtain a commutative diagram of ringed topoi

$$\begin{array}{ccc}
 (X/S)_{\text{cris}} & \longrightarrow & (Y/S')_{\text{cris}} \\
 \downarrow & & \downarrow \\
 \text{Sh}((\text{Sch}/S)_{Zar}) & \longrightarrow & \text{Sh}((\text{Sch}/S')_{Zar})
 \end{array}$$

where the vertical arrows are the structure morphisms.

45.10. Sheaves on the crystalline site

Notation and assumptions as in Situation 45.7.5. In order to discuss the small and big crystalline sites of X/S simultaneously in this section we let

$$\mathcal{C} = \text{CRIS}(X/S) \quad \text{or} \quad \mathcal{C} = \text{Cris}(X/S).$$

A sheaf \mathcal{F} on \mathcal{C} gives rise to a *restriction* \mathcal{F}_T for every object (U, T, δ) of \mathcal{C} . Namely, \mathcal{F}_T is the Zariski sheaf on the scheme T defined by the rule

$$\mathcal{F}_T(W) = \mathcal{F}(U \cap W, W, \delta|_W)$$

for $W \subset T$ is open. Moreover, if $f : T \rightarrow T'$ is a morphism between objects (U, T, δ) and (U', T', δ') of \mathcal{C} , then there is a canonical *comparison* map

$$(45.10.0.1) \quad c_f : f^{-1}\mathcal{F}_{T'} \longrightarrow \mathcal{F}_T.$$

Namely, if $W' \subset T'$ is open then f induces a morphism

$$f|_{f^{-1}W'} : (U \cap f^{-1}(W'), f^{-1}W', \delta|_{f^{-1}W'}) \longrightarrow (U' \cap W', W', \delta|_{W'})$$

of \mathcal{C} , hence we can use the restriction mapping $(f|_{f^{-1}W'})^*$ of \mathcal{F} to define a map $\mathcal{F}_{T'}(W') \rightarrow \mathcal{F}_T(f^{-1}W')$. These maps are clearly compatible with further restriction, hence define an f -map from $\mathcal{F}_{T'}$ to \mathcal{F}_T (see Sheaves, Section 6.21 and especially Sheaves, Definition 6.21.7). Thus a map c_f as in (45.10.0.1). Note that if f is an open immersion, then c_f is an isomorphism, because in that case \mathcal{F}_T is just the restriction of $\mathcal{F}_{T'}$ to T .

Conversely, given Zariski sheaves \mathcal{F}_T for every object (U, T, δ) of \mathcal{C} and comparison maps c_f as above which (a) are isomorphisms for open immersions, and (b) satisfy a suitable cocycle condition, we obtain a sheaf on \mathcal{C} . This is proved exactly as in Topologies, Lemma 33.3.18.

The *structure sheaf* on \mathcal{C} is the sheaf $\mathcal{O}_{X/S}$ defined by the rule

$$\mathcal{O}_{X/S} : (U, T, \delta) \longmapsto \Gamma(T, \mathcal{O}_T)$$

This is a sheaf by the definition of coverings in \mathcal{C} . Suppose that \mathcal{F} is a sheaf of $\mathcal{O}_{X/S}$ -modules. In this case the comparison mappings (45.10.0.1) define a comparison map

$$(45.10.0.2) \quad c_f : f^* \mathcal{F}_T \longrightarrow \mathcal{F}_{T'}$$

of \mathcal{O}_T -modules.

Another type of example comes by starting with a sheaf \mathcal{G} on $(Sch/X)_{Zar}$ or X_{Zar} (depending on whether $\mathcal{C} = CRIS(X/S)$ or $\mathcal{C} = Cris(X/S)$). Then $\underline{\mathcal{G}}$ defined by the rule

$$\underline{\mathcal{G}} : (U, T, \delta) \longmapsto \mathcal{G}(U)$$

is a sheaf on \mathcal{C} . In particular, if we take $\mathcal{G} = \mathbf{G}_a = \mathcal{O}_X$, then we obtain

$$\underline{\mathbf{G}}_a : (U, T, \delta) \longmapsto \Gamma(U, \mathcal{O}_U)$$

There is a surjective map of sheaves $\mathcal{O}_{X/S} \rightarrow \underline{\mathbf{G}}_a$ defined by the canonical maps $\Gamma(T, \mathcal{O}_T) \rightarrow \Gamma(U, \mathcal{O}_U)$ for objects (U, T, δ) . The kernel of this map is denoted $\mathcal{J}_{X/S}$, hence a short exact sequence

$$0 \rightarrow \mathcal{J}_{X/S} \rightarrow \mathcal{O}_{X/S} \rightarrow \underline{\mathbf{G}}_a \rightarrow 0$$

Note that $\mathcal{J}_{X/S}$ comes equipped with a canonical divided power structure. After all, for each object (U, T, δ) the third component δ is a divided power structure on the kernel of $\mathcal{O}_T \rightarrow \mathcal{O}_U$. Hence the (big) crystalline topos is a divided power topos.

45.11. Crystals in modules

It turns out that a crystal is a very general gadget. However, the definition may be a bit hard to parse, so we first give the definition in the case of modules on the crystalline sites.

Definition 45.11.1. In Situation 45.7.5. Let $\mathcal{C} = CRIS(X/S)$ or $\mathcal{C} = Cris(X/S)$. Let \mathcal{F} be a sheaf of $\mathcal{O}_{X/S}$ -modules on \mathcal{C} .

- (1) We say \mathcal{F} is *locally quasi-coherent* if for every object (U, T, δ) of \mathcal{C} the restriction \mathcal{F}_T is a quasi-coherent \mathcal{O}_T -module.
- (2) We say \mathcal{F} is *quasi-coherent* if it is quasi-coherent in the sense of Modules on Sites, Definition 18.23.1.
- (3) We say \mathcal{F} is a *crystal in $\mathcal{O}_{X/S}$ -modules* if all the comparison maps (45.10.0.2) are isomorphisms.

It turns out that we can relate these notions as follows.

Lemma 45.11.2. *With notation $X/S, \mathcal{I}, \gamma, \mathcal{C}, \mathcal{F}$ as in Definition 45.11.1. The following are equivalent*

- (1) \mathcal{F} is quasi-coherent, and
- (2) \mathcal{F} is locally quasi-coherent and a crystal in $\mathcal{O}_{X/S}$ -modules.

Proof. Assume (1). Let $f : (U', T', \delta') \rightarrow (U, T, \delta)$ be an object of \mathcal{C} . We have to prove (a) \mathcal{F}_T is a quasi-coherent \mathcal{O}_T -module and (b) $c_f : f^*\mathcal{F}_T \rightarrow \mathcal{F}_{T'}$ is an isomorphism. The assumption means that we can find a covering $\{(T_i, U_i, \delta_i) \rightarrow (T, U, \delta)\}$ and for each i the restriction of \mathcal{F} to $\mathcal{C}/(T_i, U_i, \delta_i)$ has a global presentation. Since it suffices to prove (a) and (b) Zariski locally, we may replace $f : (T', U', \delta') \rightarrow (T, U, \delta)$ by the base change to (T_i, U_i, δ_i) and assume that \mathcal{F} restricted to $\mathcal{C}/(T, U, \delta)$ has a global presentation

$$\bigoplus_{j \in J} \mathcal{O}_{X/S}|_{\mathcal{C}/(U, T, \delta)} \longrightarrow \bigoplus_{i \in I} \mathcal{O}_{X/S}|_{\mathcal{C}/(U, T, \delta)} \longrightarrow \mathcal{F}|_{\mathcal{C}/(U, T, \delta)} \longrightarrow 0$$

It is clear that this gives a presentation

$$\bigoplus_{j \in J} \mathcal{O}_T \longrightarrow \bigoplus_{i \in I} \mathcal{O}_T \longrightarrow \mathcal{F}_T \longrightarrow 0$$

and hence (a) holds. Moreover, the presentation restricts to T' to give a similar presentation of $\mathcal{F}_{T'}$, whence (b) holds.

Assume (2). Let (U, T, δ) be an object of \mathcal{C} . We have to find a covering of (U, T, δ) such that \mathcal{F} has a global presentation when we restrict to the localization of \mathcal{C} at the members of the covering. Thus we may assume that T is affine. In this case we can choose a presentation

$$\bigoplus_{j \in J} \mathcal{O}_T \longrightarrow \bigoplus_{i \in I} \mathcal{O}_T \longrightarrow \mathcal{F}_T \longrightarrow 0$$

as \mathcal{F}_T is assumed to be a quasi-coherent \mathcal{O}_T -module. Then by the crystal property of \mathcal{F} we see that this pulls back to a presentation of $\mathcal{F}_{T'}$ for any morphism $f : (U', T', \delta') \rightarrow (U, T, \delta)$ of \mathcal{C} . Thus the desired presentation of $\mathcal{F}|_{\mathcal{C}/(U, T, \delta)}$. \square

Definition 45.11.3. If \mathcal{F} satisfies the equivalent conditions of Lemma 45.11.2, then we say that \mathcal{F} is a *crystal in quasi-coherent modules*. We say that \mathcal{F} is a *crystal in finite locally free modules* if, in addition, \mathcal{F} is finite locally free.

Of course, as Lemma 45.11.2 shows, this notation is somewhat heavy since a quasi-coherent module is always a crystal. But it is standard terminology in the literature.

Remark 45.11.4. To formulate the general notion of a crystal we use the language of stacks and strongly cartesian morphisms, see Stacks, Definition 8.4.1 and Categories, Definition 4.31.1. In Situation 45.7.5 let $p : \mathcal{C} \rightarrow \text{Cris}(X/S)$ be a stack. A *crystal in objects of \mathcal{C} on X relative to S* is a *cartesian section* $\sigma : \text{Cris}(X/S) \rightarrow \mathcal{C}$, i.e., a functor σ such that $p \circ \sigma = \text{id}$ and such that $\sigma(f)$ is strongly cartesian for all morphisms f of $\text{Cris}(X/S)$. Similarly for the big crystalline site.

45.12. Sheaf of differentials

In this section we will stick with the (small) crystalline site as it seems more natural. We globalize Definition 45.6.1 as follows.

Definition 45.12.1. In Situation 45.7.5 let \mathcal{F} be a sheaf of $\mathcal{O}_{X/S}$ -modules on $\text{Cris}(X/S)$. An *S -derivation* $D : \mathcal{O}_{X/S} \rightarrow \mathcal{F}$ is a map of sheaves such that for every object (U, T, δ) of $\text{Cris}(X/S)$ the map

$$D : \Gamma(T, \mathcal{O}_T) \longrightarrow \Gamma(T, \mathcal{F})$$

is a divided power $\Gamma(V, \mathcal{O}_V)$ -derivation where $V \subset S$ is any open such that $T \rightarrow S$ factors through V .

This means that D is additive, satisfies the Leibniz rule, annihilates functions coming from S , and satisfies $D(f^{[n]}) = f^{[n-1]}D(f)$ for a local section f of the divided power ideal $\mathcal{J}_{X/S}$. This is a special case of a very general notion which we now describe.

Please compare the following discussion with Modules on Sites, Section 18.32. Let \mathcal{C} be a site, let $\mathcal{A} \rightarrow \mathcal{B}$ be a map of sheaves of rings on \mathcal{C} , let $\mathcal{J} \subset \mathcal{B}$ be a sheaf of ideals, let δ be a divided power structure on \mathcal{J} , and let \mathcal{F} be a sheaf of \mathcal{B} -modules. Then there is a notion of a *divided power \mathcal{A} -derivation* $D : \mathcal{B} \rightarrow \mathcal{F}$. This means that D is \mathcal{A} -linear, satisfies the Leibniz rule, and satisfies $D(\delta_n(x)) = \delta_{n-1}(x)D(x)$ for local sections x of \mathcal{J} . In this situation there exists a *universal divided power \mathcal{A} -derivation*

$$d_{\mathcal{B}/\mathcal{A},\delta} : \mathcal{B} \longrightarrow \Omega_{\mathcal{B}/\mathcal{A},\delta}$$

Moreover, $d_{\mathcal{B}/\mathcal{A},\delta}$ is the composition

$$\mathcal{B} \longrightarrow \Omega_{\mathcal{B}/\mathcal{A}} \longrightarrow \Omega_{\mathcal{B}/\mathcal{A},\delta}$$

where the first map is the universal derivation constructed in the proof of Modules on Sites, Lemma 18.32.2 and the second arrow is the quotient by the submodule generated by the local sections $d_{\mathcal{B}/\mathcal{A}}(\delta_n(x)) - \delta_{n-1}(x)d_{\mathcal{B}/\mathcal{A}}(x)$.

We translate this into a relative notion as follows. Suppose $(f, f^\#) : (Sh(\mathcal{C}), \mathcal{O}) \rightarrow (Sh(\mathcal{C}'), \mathcal{O}')$ is a morphism of ringed topoi, $\mathcal{J} \subset \mathcal{O}$ a sheaf of ideals, δ a divided power structure on \mathcal{J} , and \mathcal{F} a sheaf of \mathcal{O} -modules. In this situation we say $D : \mathcal{O} \rightarrow \mathcal{F}$ is a *divided power \mathcal{O}' -derivation* if D is a divided power $f^{-1}\mathcal{O}'$ -derivation as defined above. Moreover, we write

$$\Omega_{\mathcal{O}/\mathcal{O}',\delta} = \Omega_{\mathcal{O}/f^{-1}\mathcal{O}',\delta}$$

which is the receptacle of the universal divided power \mathcal{O}' -derivation.

Applying this to the structure morphism

$$(X/S)_{\text{Cris}} \longrightarrow Sh(S_{Zar})$$

(see Remark 45.9.6) we recover the notion of Definition 45.12.1 above. In particular, there is a universal divided power derivation

$$d_{X/S} : \mathcal{O}_{X/S} \rightarrow \Omega_{X/S}$$

Note that we omit from the notation the decoration indicating the module of differentials is compatible with divided powers (it seems unlikely anybody would ever consider the usual module of differentials of the structure sheaf on the crystalline site).

Lemma 45.12.2. *Let (T, \mathcal{J}, δ) be a divided power scheme. Let $T \rightarrow S$ be a morphism of schemes. The quotient $\Omega_{T/S} \rightarrow \Omega_{T/S,\delta}$ described above is a quasi-coherent \mathcal{O}_T -module. For $W \subset T$ affine open mapping into $V \subset S$ affine open we have*

$$\Gamma(W, \Omega_{T/S,\delta}) = \Omega_{\Gamma(W,\mathcal{O})/\Gamma(V,\mathcal{O}_V),\delta}$$

where the right hand side is as constructed in Section 45.6.

Proof. Omitted. □

Lemma 45.12.3. *In Situation 45.7.5. For (U, T, δ) in $\text{Cris}(X/S)$ the restriction $(\Omega_{X/S})_T$ to T is $\Omega_{T/S,\delta}$ and the restriction $d_{X/S}|_T$ is equal to $d_{T/S,\delta}$.*

Proof. Omitted. □

Lemma 45.12.4. *In Situation 45.7.5. For any affine object (U, T, δ) of $\text{Cris}(X/S)$ mapping into an affine open $V \subset S$ we have*

$$\Gamma((U, T, \delta), \Omega_{X/S}) = \Omega_{\Gamma(T, \mathcal{O})/\Gamma(V, \mathcal{O}_V), \delta}$$

where the right hand side is as constructed in Section 45.6.

Proof. Combine Lemmas 45.12.2 and 45.12.3. □

Lemma 45.12.5. *In Situation 45.7.5. Let (U, T, δ) be an object of $\text{Cris}(X/S)$. Let*

$$(U(1), T(1), \delta(1)) = (U, T, \delta) \times (U, T, \delta)$$

in $\text{Cris}(X/S)$. Let $\mathcal{K} \subset \mathcal{O}_{T(1)}$ be the quasi-coherent sheaf of ideals corresponding to the closed immersion $\Delta : T \rightarrow T(1)$. Then $\mathcal{K} \subset \mathcal{J}_{T(1)}$ is preserved by the divided structure on $\mathcal{J}_{T(1)}$ and we have

$$(\Omega_{X/S})_T = \mathcal{K}/\mathcal{K}^{[2]}$$

Proof. Note that $U = U(1)$ as $U \rightarrow X$ is an open immersion and as (45.9.1.1) commutes with products. Hence we see that $\mathcal{K} \subset \mathcal{J}_{T(1)}$. Given this fact the lemma follows by working affine locally on T and using Lemmas 45.12.4 and 45.6.5. □

It turns out that $\Omega_{X/S}$ is not a crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules. But it does satisfy two closely related properties (compare with Lemma 45.11.2).

Lemma 45.12.6. *In Situation 45.7.5. The sheaf of differentials $\Omega_{X/S}$ has the following two properties:*

- (1) $\Omega_{X/S}$ is locally quasi-coherent, and
- (2) for any morphism $(U, T, \delta) \rightarrow (U', T', \delta')$ of $\text{Cris}(X/S)$ where $f : T \rightarrow T'$ is a closed immersion the map $c_f : f^*(\Omega_{X/S})_{T'} \rightarrow (\Omega_{X/S})_T$ is surjective.

Proof. Part (1) follows from a combination of Lemmas 45.12.2 and 45.12.3. Part (2) follows from the fact that $(\Omega_{X/S})_T = \Omega_{T/S, \delta}$ is a quotient of $\Omega_{T/S}$ and that $f^*\Omega_{T'/S} \rightarrow \Omega_{T/S}$ is surjective. □

45.13. Two universal thickenings

The constructions in this section will help us define a connection on a crystal in modules on the crystalline site. In some sense the constructions here are the “sheafified, universal” versions of the constructions in Section 45.3.

Remark 45.13.1. In Situation 45.7.5. Let (U, T, δ) be an object of $\text{Cris}(X/S)$. Write $\Omega_{T/S, \delta} = (\Omega_{X/S})_T$, see Lemma 45.12.3. We explicitly describe a first order thickening T' of T . Namely, set

$$\mathcal{O}_{T'} = \mathcal{O}_T \oplus \Omega_{T/S, \delta}$$

with algebra structure such that $\Omega_{T/S, \delta}$ is an ideal of square zero. Let $\mathcal{J} \subset \mathcal{O}_T$ be the ideal sheaf of the closed immersion $U \rightarrow T$. Set $\mathcal{J}' = \mathcal{J} \oplus \Omega_{T/S, \delta}$. Define a divided power structure on \mathcal{J}' by setting

$$\delta'_n(f, \omega) = (\delta_n(f), \delta_{n-1}(f)\omega),$$

see Lemma 45.3.1. There are two ring maps

$$p_0, p_1 : \mathcal{O}_T \rightarrow \mathcal{O}_{T'}$$

The first is given by $f \mapsto (f, 0)$ and the second by $f \mapsto (f, d_{T/S, \delta}f)$. Note that both are compatible with the divided power structures on \mathcal{J} and \mathcal{J}' and so is the

quotient map $\mathcal{O}_{T'} \rightarrow \mathcal{O}_T$. Thus we get an object (U, T', δ') of $\text{Cris}(X/S)$ and a commutative diagram

$$\begin{array}{ccccc}
 & & T & & \\
 & \text{id} \swarrow & \downarrow i & \searrow \text{id} & \\
 T & \xleftarrow{p_0} & T' & \xrightarrow{p_1} & T
 \end{array}$$

of $\text{Cris}(X/S)$ such that i is a first order thickening whose ideal sheaf is identified with $\Omega_{T/S,\delta}$ and such that $p_1^* - p_0^* : \mathcal{O}_T \rightarrow \mathcal{O}_{T'}$ is identified with the universal derivation $d_{T/S,\delta}$ composed with the inclusion $\Omega_{T/S,\delta} \rightarrow \mathcal{O}_{T'}$.

Remark 45.13.2. In Situation 45.7.5. Let (U, T, δ) be an object of $\text{Cris}(X/S)$. Write $\Omega_{T/S,\delta} = (\Omega_{X/S})_T$, see Lemma 45.12.3. We also write $\Omega_{T/S,\delta}^2$ for its second exterior power. We explicitly describe a second order thickening T'' of T . Namely, set

$$\mathcal{O}_{T''} = \mathcal{O}_T \oplus \Omega_{T/S,\delta} \oplus \Omega_{T/S,\delta}^2$$

with algebra structure defined in the following way

$$(f, \omega_1, \omega_2, \eta) \cdot (f', \omega'_1, \omega'_2, \eta') = (ff', f\omega'_1 + f'\omega_1, f\omega'_2 + f'\omega_2, f\eta' + f'\eta + \omega_1 \wedge \omega'_2 + \omega'_1 \wedge \omega_2).$$

Let $\mathcal{J} \subset \mathcal{O}_T$ be the ideal sheaf of the closed immersion $U \rightarrow T$. Let \mathcal{J}'' be the inverse image of \mathcal{J} under the projection $\mathcal{O}_{T''} \rightarrow \mathcal{O}_T$. Define a divided power structure on \mathcal{J}'' by setting

$$\delta''_n(f, \omega_1, \omega_2, \eta) = (\delta_n(f), \delta_{n-1}(f)\omega_1, \delta_{n-1}(f)\omega_2, \delta_{n-1}(f)\eta + \delta_{n-2}(f)\omega_1 \wedge \omega_2)$$

see Lemma 45.3.2. There are three ring maps $q_0, q_1, q_2 : \mathcal{O}_T \rightarrow \mathcal{O}_{T''}$ given by

$$\begin{aligned}
 q_0(f) &= (f, 0, 0, 0), \\
 q_1(f) &= (f, df, 0, 0), \\
 q_2(f) &= (f, df, df, 0)
 \end{aligned}$$

where $d = d_{T/S,\delta}$. Note that all three are compatible with the divided power structures on \mathcal{J} and \mathcal{J}'' . There are three ring maps $q_{01}, q_{12}, q_{02} : \mathcal{O}_{T'} \rightarrow \mathcal{O}_{T''}$ where $\mathcal{O}_{T'}$ is as in Remark 45.13.1. Namely, set

$$\begin{aligned}
 q_{01}(f, \omega) &= (f, \omega, 0, 0), \\
 q_{12}(f, \omega) &= (f, df, \omega, d\omega), \\
 q_{02}(f, \omega) &= (f, \omega, \omega, 0)
 \end{aligned}$$

These are also compatible with the given divided power structures. Let's do the verifications for q_{12} : Note that q_{12} is a ring homomorphism as

$$\begin{aligned}
 q_{12}(f, \omega)q_{12}(g, \eta) &= (f, df, \omega, d\omega)(g, dg, \eta, d\eta) \\
 &= (fg, fdg + gdf, f\eta + g\omega, fd\eta + gd\omega + df \wedge \eta + dg \wedge \omega) \\
 &= q_{12}(fg, f\eta + g\omega) = q_{12}((f, \omega)(g, \eta))
 \end{aligned}$$

Note that q_{12} is compatible with divided powers because

$$\begin{aligned}
 \delta''_n(q_{12}(f, \omega)) &= \delta''_n((f, df, \omega, d\omega)) \\
 &= (\delta_n(f), \delta_{n-1}(f)df, \delta_{n-1}(f)\omega, \delta_{n-1}(f)d\omega + \delta_{n-2}(f)d(f) \wedge \omega) \\
 &= q_{12}((\delta_n(f), \delta_{n-1}(f)\omega)) = q_{12}(\delta'_n(f, \omega))
 \end{aligned}$$

The verifications for q_{01} and q_{02} are easier. Note that $q_0 = q_{01} \circ p_0$, $q_1 = q_{01} \circ p_1$, $q_1 = q_{12} \circ p_0$, $q_2 = q_{12} \circ p_1$, $q_0 = q_{02} \circ p_0$, and $q_2 = q_{02} \circ p_1$. Thus (U, T'', δ'') is an object of $\text{Cris}(X/S)$ and we get morphisms

$$T'' \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} T' \xrightarrow{\quad} T$$

of $\text{Cris}(X/S)$ satisfying the relations described above. In applications we will use $q_i : T'' \rightarrow T$ and $q_{ij} : T'' \rightarrow T'$ to denote the morphisms associated to the ring maps described above.

45.14. The de Rham complex

In Situation 45.7.5. Working on the (small) crystalline site, we define $\Omega_{X/S}^i = \wedge^i_{\mathcal{O}_{X/S}} \Omega_{X/S}$ for $i \geq 0$. The universal S -derivation $d_{X/S}$ gives rise to the *de Rham complex*

$$\mathcal{O}_{X/S} \rightarrow \Omega_{X/S}^1 \rightarrow \Omega_{X/S}^2 \rightarrow \dots$$

on $\text{Cris}(X/S)$, see Lemma 45.12.4 and Remark 45.6.9.

45.15. Connections

In Situation 45.7.5. Given an $\mathcal{O}_{X/S}$ -module \mathcal{F} on $\text{Cris}(X/S)$ a *connection* is a map of abelian sheaves

$$\nabla : \mathcal{F} \longrightarrow \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}$$

such that $\nabla(fs) = f\nabla(s) + s \otimes df$ for local sections s, f of \mathcal{F} and $\mathcal{O}_{X/S}$. Given a connection there are canonical maps $\nabla : \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^i \longrightarrow \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^{i+1}$ defined by the rule $\nabla(s \otimes \omega) = \nabla(s) \wedge \omega + s \otimes d\omega$ as in Remark 45.6.10. We say the connection is *integrable* if $\nabla \circ \nabla = 0$. If ∇ is integrable we obtain the *de Rham complex*

$$\mathcal{F} \rightarrow \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^1 \rightarrow \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^2 \rightarrow \dots$$

on $\text{Cris}(X/S)$. It turns out that any crystal in $\mathcal{O}_{X/S}$ -modules comes equipped with a canonical integrable connection.

Lemma 45.15.1. *In Situation 45.7.5. Let \mathcal{F} be a crystal in $\mathcal{O}_{X/S}$ -modules on $\text{Cris}(X/S)$. Then \mathcal{F} comes equipped with a canonical integrable connection.*

Proof. Say (U, T, δ) is an object of $\text{Cris}(X/S)$. Let (U, T', δ') be the infinitesimal thickening of T by $(\Omega_{X/S})_T = \Omega_{T/S, \delta}$ constructed in Remark 45.13.1. It comes with projections $p_0, p_1 : T' \rightarrow T$ and a diagonal $i : T \rightarrow T(1)$. By assumption we get isomorphisms

$$p_0^* \mathcal{F}_T \xrightarrow{c_0} \mathcal{F}_{T'} \xleftarrow{c_1} p_1^* \mathcal{F}_T$$

of $\mathcal{O}_{T'}$ -modules. Pulling $c = c_1^{-1} \circ c_0$ back to T by i we obtain the identity map of \mathcal{F}_T . Hence if $s \in \Gamma(T, \mathcal{F}_T)$ then $\nabla(s) = p_1^* s - c(p_0^* s)$ is a section of $p_1^* \mathcal{F}_T$ which vanishes on pulling back by Δ . Hence $\nabla(s)$ is a section of

$$\mathcal{F}_T \otimes_{\mathcal{O}_T} \Omega_{T/S, \delta}$$

because this is the kernel of $p_1^* \mathcal{F}_T \rightarrow \mathcal{F}_T$ as $\Omega_{T/S, \delta}$ is the kernel of $\mathcal{O}_{T'} \rightarrow \mathcal{O}_T$ by construction.

The collection of maps

$$\nabla : \Gamma(T, \mathcal{F}_T) \rightarrow \Gamma(T, \mathcal{F}_T \otimes_{\mathcal{O}_T} \Omega_{T/S, \delta})$$

so obtained is functorial in T because the construction of T' is functorial in T . Hence we obtain a connection.

To show that the connection is integrable we consider the object (U, T'', δ'') constructed in Remark 45.13.2. Because \mathcal{F} is a sheaf we see that

$$\begin{array}{ccc}
 q_0^* \mathcal{F}_T & \xrightarrow{\quad} & q_1^* \mathcal{F}_T \\
 & \searrow^{q_{0_1^* c}} & \swarrow_{q_{1_2^* c}} \\
 & & q_2^* \mathcal{F}_T
 \end{array}$$

is a commutative map of $\mathcal{O}_{T''}$ -modules. For $s \in \Gamma(T, \mathcal{F}_T)$ we have $c(p_0^* s) = p_1^* s - \nabla(s)$. Write $\nabla(s) = \sum p_1^* s_i \cdot \omega_i$ where s_i is a local section of \mathcal{F}_T and ω_i is a local section of $\Omega_{T/S, \delta}$. We think of ω_i as a local section of the structure sheaf of $\mathcal{O}_{T'}$ and hence we write product instead of tensor product. On the one hand

$$\begin{aligned}
 q_{1_2^*} c \circ q_{0_1^*} c(q_0^* s) &= q_{1_2^*} c(q_1^* s - \sum q_1^* s_i \cdot q_{0_1^*} \omega_i) \\
 &= q_2^* s - \sum q_2^* s_i \cdot q_{1_2^*} \omega_i - \sum q_2^* s_i \cdot q_{0_1^*} \omega_i + \sum q_{1_2^*} \nabla(s_i) \cdot q_{0_1^*} \omega_i
 \end{aligned}$$

and on the other hand

$$q_{0_2^*} c(q_0^* s) = q_2^* s - \sum q_2^* s_i \cdot q_{0_2^*} \omega_i.$$

From the formulae of Remark 45.13.2 we see that $q_{0_1^*} \omega_i + q_{1_2^*} \omega_i - q_{0_2^*} \omega_i = d\omega_i$. Hence the difference of the two expressions above is

$$\sum q_2^* s_i \cdot d\omega_i - \sum q_{1_2^*} \nabla(s_i) \cdot q_{0_1^*} \omega_i$$

Note that $q_{1_2^*} \omega \cdot q_{0_1^*} \omega' = \omega' \wedge \omega = -\omega \wedge \omega'$ by the definition of the multiplication on $\mathcal{O}_{T''}$. Thus the expression above is $\nabla^2(s)$ viewed as a section of the subsheaf $\mathcal{F}_T \otimes \Omega_{T/S, \delta}^2$ of $q_2^* \mathcal{F}$. Hence we get the integrability condition. \square

45.16. Cosimplicial algebra

This section should be moved somewhere else. A *cosimplicial ring* is a cosimplicial object in the category of rings. Given a ring R , a *cosimplicial R -algebra* is a cosimplicial object in the category of R -algebras. A *cosimplicial ideal* in a cosimplicial ring A_* is given by an ideal $I_n \subset A_n$ for all n such that $A(f)(I_n) \subset I_m$ for all $f : [n] \rightarrow [m]$ in Δ .

Let A_* be a cosimplicial ring. Let \mathcal{C} be the category of pairs (A, M) where A is a ring and M is a module over A . A morphism $(A, M) \rightarrow (A', M')$ consists of a ring map $A \rightarrow A'$ and an A -module map $M \rightarrow M'$ where M' is viewed as an A -module via $A \rightarrow A'$ and the A' -module structure on M' . Having said this we can define a *cosimplicial module M_* over A_** as a cosimplicial object (A_*, M_*) of \mathcal{C} whose first entry is equal to A_* . A *homomorphism $\varphi_* : M_* \rightarrow N_*$ of cosimplicial modules over A_** is a morphism $(A_*, M_*) \rightarrow (A_*, N_*)$ of cosimplicial objects in \mathcal{C} whose first component is 1_{A_*} .

A *homotopy* between homomorphisms $\varphi_*, \psi_* : M_* \rightarrow N_*$ of cosimplicial modules over A_* is a homotopy between the associated maps $(A_*, M_*) \rightarrow (A_*, N_*)$ whose first component is the trivial homotopy (dual to Simplicial, Example 14.25.3). We spell out what this means. Such a homotopy is a homotopy

$$h : M_* \longrightarrow \text{Hom}(\Delta[1], N_*)$$

between φ_* and ψ_* as homomorphisms of cosimplicial abelian groups such that for each n the map $h_n : M_n \rightarrow \prod_{\alpha \in \Delta[1]_n} N_n$ is A_n -linear. The following lemma is a version of Simplicial, Lemma 14.27.3 for cosimplicial modules.

Lemma 45.16.1. *Let A_* be a cosimplicial ring. Let $\varphi_*, \psi_* : K_* \rightarrow M_*$ be homomorphisms of cosimplicial A_* -modules.*

(1) *If φ_* and ψ_* are homotopic, then*

$$\varphi_* \otimes 1, \psi_* \otimes 1 : K_* \otimes_{A_*} L_* \longrightarrow M_* \otimes_{A_*} L_*$$

are homotopic for any cosimplicial A_ -module L_* .*

(2) *If φ_* and ψ_* are homotopic, then*

$$\wedge^i(\varphi_*), \wedge^i(\psi_*) : \wedge^i(K_*) \longrightarrow \wedge^i(M_*)$$

are homotopic.

(3) *If φ_* and ψ_* are homotopic, and $A_* \rightarrow B_*$ is a homomorphism of cosimplicial rings, then*

$$\varphi_* \otimes 1, \psi_* \otimes 1 : K_* \otimes_{A_*} B_* \longrightarrow M_* \otimes_{A_*} B_*$$

are homotopic as homomorphisms of cosimplicial B_ -modules.*

(4) *If $I_* \subset A_*$ is a cosimplicial ideal, then the induced maps*

$$\varphi_*^\wedge, \psi_*^\wedge : K_*^\wedge \longrightarrow M_*^\wedge$$

between completions are homotopic.

(5) *Add more here as needed, for example symmetric powers.*

Proof. Let $h : M_* \rightarrow \text{Hom}(\Delta[1], N_*)$ be the given homotopy. In degree n we have

$$h_n = (h_{n,\alpha}) : K_n \longrightarrow \prod_{\alpha \in \Delta[1]_n} K_n$$

see Simplicial, Section 14.27. In order for a collection of $h_{n,\alpha}$ to form a homotopy, it is necessary and sufficient if for every $f : [n] \rightarrow [m]$ we have

$$h_{m,\alpha} \circ M_*(f) = N_*(f) \circ h_{n,\alpha \circ f}$$

see Simplicial, Equation (14.27.1.1). We also should have that $\psi_n = h_{n,0:[n] \rightarrow [1]}$ and $\varphi_n = h_{n,1:[n] \rightarrow [1]}$.

In each of the cases of the lemma we can produce the corresponding maps. Case

(1). We can use the homotopy $h \otimes 1$ defined in degree n by setting

$$(h \otimes 1)_{n,\alpha} = h_{n,\alpha} \otimes 1_{L_n} : K_n \otimes_{A_n} L_n \longrightarrow M_n \otimes_{A_n} L_n.$$

Case (2). We can use the homotopy $\wedge^i h$ defined in degree n by setting

$$\wedge^i(h)_{n,\alpha} = \wedge^i(h_{n,\alpha}) : \wedge_{A_n}^i(K_n) \longrightarrow \wedge_{A_n}^i(M_n).$$

Case (3). We can use the homotopy $h \otimes 1$ defined in degree n by setting

$$(h \otimes 1)_{n,\alpha} = h_{n,\alpha} \otimes 1 : K_n \otimes_{A_n} B_n \longrightarrow M_n \otimes_{A_n} B_n.$$

Case (4). We can use the homotopy h^\wedge defined in degree n by setting

$$(h^\wedge)_{n,\alpha} = h_{n,\alpha}^\wedge : K_n^\wedge \longrightarrow M_n^\wedge.$$

This works because each $h_{n,\alpha}$ is A_n -linear. □

45.17. Crystals in quasi-coherent modules

In Situation 45.5.1. Set $X = \text{Spec}(C)$ and $S = \text{Spec}(A)$. We are going to classify crystals in quasi-coherent modules on $\text{Cris}(X/S)$. Before we do so we fix some notation.

Choose a polynomial ring $P = A[x_i]$ over A and a surjection $P \rightarrow C$ of A -algebras with kernel $J = \text{Ker}(P \rightarrow C)$. Set

$$(45.17.0.1) \quad D = \lim_e D_{P,\gamma}(J)/p^e D_{P,\gamma}(J)$$

for the p -adically completed divided power envelope. This ring comes with a divided power ideal \bar{J} and divided power structure $\bar{\gamma}$, see Lemma 45.5.5. Set $D_e = D/p^e D$ and denote \bar{J}_e the image of \bar{J} in D_e . We will use the short hand

$$(45.17.0.2) \quad \Omega_D = \lim_e \Omega_{D_e/A,\bar{\gamma}} = \lim_e \Omega_{D/A,\bar{\gamma}}/p^e \Omega_{D/A,\bar{\gamma}}$$

for the p -adic completion of the module of divided power differentials, see Lemma 45.6.12. It is also the p -adic completion of $\Omega_{D_{P,\gamma}(J)/A,\bar{\gamma}}$ which is free on dx_i , see Lemma 45.6.6. Hence any element of Ω_D can be written uniquely as a sum $\sum f_i dx_i$ with for all e only finitely many f_i not in $p^e D$. Moreover, the maps $d_{D_e/A,\bar{\gamma}} : D_e \rightarrow \Omega_{D_e/A,\bar{\gamma}}$ fit together to define a divided power A -derivation

$$(45.17.0.3) \quad d : D \longrightarrow \Omega_D$$

on p -adic completions.

We will also need the “products $\text{Spec}(D(n))$ of $\text{Spec}(D)$ ”, see Proposition 45.21.1 and its proof for an explanation. Formally these are defined as follows. For $n \geq 0$ let $J(n) = \text{Ker}(P \otimes_A \dots \otimes_A P \rightarrow C)$ where the tensor product has $n + 1$ factors. We set

$$(45.17.0.4) \quad D(n) = \lim_e D_{P \otimes_A \dots \otimes_A P,\gamma}(J(n))/p^e D_{P \otimes_A \dots \otimes_A P,\gamma}(J(n))$$

equal to the p -adic completion of the divided power envelope. We denote $\bar{J}(n)$ its divided power ideal and $\bar{\gamma}(n)$ its divided powers. We also introduce $D(n)_e = D(n)/p^e D(n)$ as well as the p -adically completed module of differentials

$$(45.17.0.5) \quad \Omega_{D(n)} = \lim_e \Omega_{D(n)_e/A,\bar{\gamma}} = \lim_e \Omega_{D(n)/A,\bar{\gamma}}/p^e \Omega_{D(n)/A,\bar{\gamma}}$$

and derivation

$$(45.17.0.6) \quad d : D(n) \longrightarrow \Omega_{D(n)}$$

Of course we have $D = D(0)$. Note that the rings $D(0), D(1), D(2), \dots$ form a cosimplicial object in the category of divided power rings.

Lemma 45.17.1. *Let D and $D(n)$ be as in (45.17.0.1) and (45.17.0.4). The coprojection $P \rightarrow P \otimes_A \dots \otimes_A P$, $f \mapsto f \otimes 1 \otimes \dots \otimes 1$ induces an isomorphism*

$$(45.17.1.1) \quad D(n) = \lim_e D\langle \xi_i(j) \rangle / p^e D\langle \xi_i(j) \rangle$$

of algebras over D with

$$\xi_i(j) = x_i \otimes 1 \otimes \dots \otimes 1 - 1 \otimes \dots \otimes 1 \otimes x_i \otimes 1 \otimes \dots \otimes 1$$

for $j = 1, \dots, n$.

Proof. We have

$$P \otimes_A \dots \otimes_A P = P[\xi_i(j)]$$

and $J(n)$ is generated by J and the elements $\xi_i(j)$. Hence the lemma follows from Lemma 45.2.5. □

Lemma 45.17.2. *Let D and $D(n)$ be as in (45.17.0.1) and (45.17.0.4). Then $(D, \bar{J}, \bar{\gamma})$ and $(D(n), \bar{J}(n), \bar{\gamma}(n))$ are objects of $\text{Cris}^\wedge(C/A)$, see Remark 45.5.4, and*

$$D(n) = \coprod_{j=0, \dots, n} D$$

in $\text{Cris}^\wedge(C/A)$.

Proof. The first assertion is clear. For the second, if $(B \rightarrow C, \delta)$ is an object of $\text{Cris}^\wedge(C/A)$, then we have

$$\text{Mor}_{\text{Cris}^\wedge(C/A)}(D, B) = \text{Hom}_A((P, J), (B, \text{Ker}(B \rightarrow C)))$$

and similarly for $D(n)$ replacing (P, J) by $(P \otimes_A \dots \otimes_A P, J(n))$. The property on coproducts follows as $P \otimes_A \dots \otimes_A P$ is a coproduct. \square

In the lemma below we will consider pairs (M, ∇) satisfying the following conditions

- (1) M is a p -adically complete D -module,
- (2) $\nabla : M \rightarrow M \otimes_D^\wedge \Omega_D$ is a connection, i.e., $\nabla(fm) = m \otimes df + f\nabla(m)$,
- (3) ∇ is integrable (see Remark 45.6.10), and
- (4) ∇ is *topologically quasi-nilpotent*: If we write $\nabla(m) = \sum \theta_i(m)dx_i$ for some operators $\theta_i : M \rightarrow M$, then for any $m \in M$ there are only finitely many pairs (i, k) such that $\theta_i^k(m) \notin pM$.

The operators θ_i are sometimes denoted $\nabla_{\partial/\partial x_i}$ in the literature. In the following lemma we construct a functor from crystals in quasi-coherent modules on $\text{Cris}(X/S)$ to the category of such pairs. We will show this functor is an equivalent in Proposition 45.17.4.

Lemma 45.17.3. *In the situation above there is a functor*

$$\begin{array}{ccc} \text{crystals in quasi-coherent} & \longrightarrow & \text{pairs } (M, \nabla) \text{ satisfying} \\ \mathcal{O}_{X/S}\text{-modules on } \text{Cris}(X/S) & & (1), (2), (3), \text{ and } (4) \end{array}$$

Proof. Let \mathcal{F} be a crystal in quasi-coherent modules on X/S . Set $T_e = \text{Spec}(D_e)$ so that $(X, T_e, \bar{\gamma})$ is an object of $\text{Cris}(X/S)$ for $e \gg 0$. We have morphisms

$$(X, T_e, \bar{\gamma}) \rightarrow (X, T_{e+1}, \bar{\gamma}) \rightarrow \dots$$

which are closed immersions. We set

$$M = \lim_e \Gamma((X, T_e, \bar{\gamma}), \mathcal{F}) = \lim_e \Gamma(T_e, \mathcal{F}_{T_e}) = \lim_e M_e$$

Note that since \mathcal{F} is locally quasi-coherent we have $\mathcal{F}_{T_e} = \widetilde{M}_e$. Since \mathcal{F} is a crystal we have $M_e = M_{e+1}/p^e M_{e+1}$. Hence we see that $M_e = M/p^e M$ and that M is p -adically complete.

By Lemma 45.15.1 we know that \mathcal{F} comes endowed with a canonical integrable connection $\nabla : \mathcal{F} \rightarrow \mathcal{F} \otimes \Omega_{X/S}$. If we evaluate this connection on the objects T_e constructed above we obtain a canonical integrable connection

$$\nabla : M \longrightarrow M \otimes_D^\wedge \Omega_D$$

To see that this is topologically nilpotent we work out what this means.

Now we can do the same procedure for the rings $D(n)$. This produces a p -adically complete $D(n)$ -module $M(n)$. Again using the crystal property of \mathcal{F} we obtain isomorphisms

$$M \otimes_{D, p_0}^\wedge D(1) \rightarrow M(1) \leftarrow M \otimes_{D, p_1}^\wedge D(1)$$

compare with the proof of Lemma 45.15.1. Denote c the composition from left to right. Pick $m \in M$. Write $\xi_i = x_i \otimes 1 - 1 \otimes x_i$. Using (45.17.1.1) we can write uniquely

$$c(m \otimes 1) = \sum_K \theta_K(m) \otimes \prod \xi_i^{[k_i]}$$

for some $\theta_K(m) \in M$ where the sum is over multi-indices $K = (k_i)$ with $k_i \geq 0$ and $\sum k_i < \infty$. Set $\theta_i = \theta_K$ where K has a 1 in the i th spot and zeros elsewhere. We have

$$\nabla(m) = \sum \theta_i(m) dx_i.$$

as can be seen by comparing with the definition of ∇ . Namely, the defining equation is $p_1^*m = \nabla(m) - c(p_0^*m)$ in Lemma 45.15.1 but the sign works out because in the stacks project we consistently use $df = p_1(f) - p_0(f)$ modulo the ideal of the diagonal squared, and hence $\xi_i = x_i \otimes 1 - 1 \otimes x_i$ maps to $-dx_i$ modulo the ideal of the diagonal squared.

Denote $q_i : D \rightarrow D(2)$ and $q_{ij} : D(1) \rightarrow D(2)$ the coprojections corresponding to the indices i, j . As in the last paragraph of the proof of Lemma 45.15.1 we see that

$$q_{02}^*c = q_{12}^*c \circ q_{01}^*c.$$

This means that

$$\sum_{K''} \theta_{K''}(m) \otimes \prod \zeta_i''^{[k_i'']} = \sum_{K',K} \theta_{K'}(\theta_K(m)) \otimes \prod \zeta_i'^{[k_i']} \prod \zeta_i^{[k_i]}$$

in $M \otimes_{\hat{D}, q_2} D(2)$ where

$$\begin{aligned} \zeta_i &= x_i \otimes 1 \otimes 1 - 1 \otimes x_i \otimes 1, \\ \zeta_i' &= 1 \otimes x_i \otimes 1 - 1 \otimes 1 \otimes x_i, \\ \zeta_i'' &= x_i \otimes 1 \otimes 1 - 1 \otimes 1 \otimes x_i. \end{aligned}$$

In particular $\zeta_i'' = \zeta_i + \zeta_i'$ and we have that $D(2)$ is the p -adic completion of the divided power polynomial ring in ζ_i, ζ_i' over $q_2(D)$, see Lemma 45.17.1. Comparing coefficients in the expression above it follows immediately that $\theta_i \circ \theta_j = \theta_j \circ \theta_i$ (this provides an alternative proof of the integrability of ∇) and that

$$\theta_K(m) = \left(\prod \theta_i^{k_i} \right)(m).$$

In particular, as the sum expressing $c(m \otimes 1)$ above has to converge p -adically we conclude that for each i and each $m \in M$ only a finite number of $\theta_i^{k_i}(m)$ are allowed to be nonzero modulo p . □

Proposition 45.17.4. *The functor*

$$\begin{array}{ccc} \text{crystals in quasi-coherent} & \longrightarrow & \text{pairs } (M, \nabla) \text{ satisfying} \\ \mathcal{O}_{X/S}\text{-modules on } \text{Cris}(X/S) & & (1), (2), (3), \text{ and } (4) \end{array}$$

of Lemma 45.17.3 is an equivalence of categories.

Proof. Let (M, ∇) be given. We are going to construct a crystal in quasi-coherent modules \mathcal{F} . Write $\nabla(m) = \sum \theta_i(m) dx_i$. Then $\theta_i \circ \theta_j = \theta_j \circ \theta_i$ and we can set $\theta_K(m) = \left(\prod \theta_i^{k_i} \right)(m)$ for any multi-index $K = (k_i)$ with $k_i \geq 0$ and $\sum k_i < \infty$.

Let (U, T, δ) be any object of $\text{Cris}(X/S)$ with T affine. Say $T = \text{Spec}(B)$ and the ideal of $U \rightarrow T$ is $J_B \subset B$. By Lemma 45.5.6 there exists an integer e and a morphism

$$f : (U, T, \delta) \longrightarrow (X, T_e, \bar{\gamma})$$

where $T_e = \text{Spec}(D_e)$ as in the proof of Lemma 45.17.3. Choose such an e and f ; denote $f : D \rightarrow B$ also the corresponding divided power A -algebra map. We will set \mathcal{F}_T equal to the quasi-coherent sheaf of \mathcal{O}_T -modules associated to the B -module

$$M \otimes_{D,f} B.$$

However, we have to show that this is independent of the choice of f . Suppose that $g : D \rightarrow B$ is a second such morphism. Since f and g are morphisms in $\text{Cris}(X/S)$ we see that the image of $f - g : D \rightarrow B$ is contained in the divided power ideal J_B . Write $\xi_i = f(x_i) - g(x_i) \in J_B$. By analogy with the proof of Lemma 45.17.3 we define an isomorphism

$$c_{f,g} : M \otimes_{D,f} B \longrightarrow M \otimes_{D,g} B$$

by the formula

$$m \otimes 1 \longmapsto \sum_K \theta_K(m) \otimes \prod \xi_i^{[k_i]}$$

which makes sense by our remarks above and the fact that ∇ is topologically quasi-nilpotent (so the sum is finite!). A computation shows that

$$c_{g,h} \circ c_{f,g} = c_{f,h}$$

if given a third morphism $h : (U, T, \delta) \rightarrow (X, T_e, \bar{\gamma})$. It is also true that $c_{f,f} = 1$. Hence these maps are all isomorphisms and we see that the module \mathcal{F}_T is independent of the choice of f .

If $a : (U', T', \delta') \rightarrow (U, T, \delta)$ is a morphism of affine objects of $\text{Cris}(X/S)$, then choosing $f' = f \circ a$ it is clear that there exists a canonical isomorphism $a^* \mathcal{F}_T \rightarrow \mathcal{F}_{T'}$. We omit the verification that this map is independent of the choice of f . Using these maps as the restriction maps it is clear that we obtain a crystal in quasi-coherent modules on the full subcategory of $\text{Cris}(X/S)$ consisting of affine objects. We omit the proof that this extends to a crystal on all of $\text{Cris}(X/S)$. We also omit the proof that this procedure is a functor and that it is quasi-inverse to the functor constructed in Lemma 45.17.3. \square

Lemma 45.17.5. *In Situation 45.5.1. Let $A \rightarrow P' \rightarrow C$ be ring maps with $A \rightarrow P'$ smooth and $P' \rightarrow C$ surjective with kernel J' . Let D' be the p -adic completion of $D_{P',\gamma}(J')$. There are homomorphisms of divided power A -algebras*

$$a : D \longrightarrow D', \quad b : D' \longrightarrow D$$

compatible with the maps $D \rightarrow C$ and $D' \rightarrow C$ such that $a \circ b = id_{D'}$. These maps induce an equivalence of categories of pairs (M, ∇) satisfying (1), (2), (3), and (4) over D and pairs (M', ∇') satisfying (1), (2), (3), and (4) over D' . In particular, the equivalence of categories of Proposition 45.17.4 also holds for the corresponding functor towards pairs over D' .

Proof. We can pick the map $P = A[x_i] \rightarrow C$ such that it factors through a surjection of A -algebras $P \rightarrow P'$ (we may have to increase the number of variables in P to do this). Hence we obtain a surjective map $a : D \rightarrow D'$ by functoriality of divided power envelopes and completion. Pick e large enough so that D_e is a divided power thickening of C over A . Then $D_e \rightarrow C$ is a surjection whose kernel is locally nilpotent, see Divided Power Algebra, Lemma 23.2.6. Setting $D'_e = D'/p^e D'$ we see that the kernel of $D_e \rightarrow D'_e$ is locally nilpotent. Hence by Algebra, Lemma 10.133.16 we can find a lift $\beta_e : P' \rightarrow D_e$ of the map $P' \rightarrow D'_e$. Note that $D_{e+i+1} \rightarrow D_{e+i} \times_{D'_{e+i}} D'_{e+i+1}$ is surjective with square zero kernel for any

$i \geq 0$ because $p^{e+i}D \rightarrow p^{e+i}D'$ is surjective. Applying the usual lifting property (Algebra, Proposition 10.133.13) successively to the diagrams

$$\begin{array}{ccc} P' & \longrightarrow & D_{e+i} \times_{D'_{e+i}} D'_{e+i+1} \\ \uparrow & & \uparrow \\ A & \longrightarrow & D_{e+i+1} \end{array}$$

we see that we can find an A -algebra map $\beta : P' \rightarrow D$ whose composition with a is the given map $P' \rightarrow D'$. By the universal property of the divided power envelope we obtain a map $D_{P',\gamma}(J') \rightarrow D$. As D is p -adically complete we obtain $b : D' \rightarrow D$ such that $a \circ b = \text{id}_{D'}$.

Consider the base change functor

$$(M, \nabla) \mapsto (M \otimes_D^\wedge D', \nabla')$$

from pairs for D to pairs for D' , see Remark 45.6.11. Similarly, we have the base change functor corresponding to the divided power homomorphism $D' \rightarrow D$. To finish the proof of the lemma we have to show that the base change for the compositions $b \circ a : D \rightarrow D$ and $a \circ b : D' \rightarrow D'$ are isomorphic to the identity functor. This is clear for the second as $a \circ b = \text{id}_{D'}$. To prove it for the first, we use the functorial isomorphism

$$c_{\text{id}_D, b \circ a} : M \otimes_{D, \text{id}_D} D \longrightarrow M \otimes_{D, b \circ a} D$$

of the proof of Proposition 45.17.4. The only thing to prove is that these maps are horizontal, which we omit.

The last statement of the proof now follows. □

Remark 45.17.6. The equivalence of Proposition 45.17.4 holds if we start with a surjection $P \rightarrow C$ where P/A satisfies the strong lifting property of Algebra, Lemma 10.133.16. To prove this we can argue as in the proof of Lemma 45.17.5. (Details will be added here if we ever need this.) Presumably there is also a direct proof of this result, but the advantage of using polynomial rings is that the rings $D(n)$ are p -adic completions of divided power polynomial rings and the algebra is simplified.

45.18. General remarks on cohomology

In this section we do a bit of work to translate the cohomology of modules on the crystalline site of an affine scheme into an algebraic question.

Lemma 45.18.1. *In Situation 45.7.5. Let \mathcal{F} be a locally quasi-coherent $\mathcal{O}_{X/S}$ -module on $\text{Cris}(X/S)$. Then we have*

$$H^p((U, T, \delta), \mathcal{F}) = 0$$

for all $p > 0$ and all (U, T, δ) with T or U affine.

Proof. As $U \rightarrow T$ is a thickening we see that U is affine if and only if T is affine, see Limits, Lemma 31.10.1. Having said this, let us apply Cohomology on Sites, Lemma 21.11.9 to the collection \mathcal{B} of affine objects (U, T, δ) and the collection Cov of affine open coverings $\mathcal{U} = \{(U_i, T_i, \delta_i) \rightarrow (U, T, \delta)\}$. The Čech complex $\check{C}^*(\mathcal{U}, \mathcal{F})$ for such a covering is simply the Čech complex of the quasi-coherent \mathcal{O}_T -module \mathcal{F}_T (here

we are using the assumption that \mathcal{F} is locally quasi-coherent) with respect to the affine open covering $\{T_i \rightarrow T\}$ of the affine scheme T . Hence the Čech cohomology is zero by Cohomology of Schemes, Lemma 29.2.5 and 29.2.2. Thus the hypothesis of Cohomology on Sites, Lemma 21.11.9 are satisfied and we win. \square

Lemma 45.18.2. *In Situation 45.7.5. Assume moreover X and S are affine schemes. Consider the full subcategory $\mathcal{C} \subset \text{Cris}(X/S)$ consisting of divided power thickenings (X, T, δ) endowed with the chaotic topology (see Sites, Example 7.6.6). For any locally quasi-coherent $\mathcal{O}_{X/S}$ -module \mathcal{F} we have*

$$R\Gamma(\mathcal{C}, \mathcal{F}|_{\mathcal{C}}) = R\Gamma(\text{Cris}(X/S), \mathcal{F})$$

Proof. We will use without further mention that \mathcal{C} and $\text{Cris}(X/S)$ have products and fibre products, see Lemma 45.8.2. Note that the inclusion functor $u : \mathcal{C} \rightarrow \text{Cris}(X/S)$ is fully faithful, continuous and commutes with products and fibre products. We claim it defines a morphism of ringed sites

$$f : (\text{Cris}(X/S), \mathcal{O}_{X/S}) \longrightarrow (\text{Sh}(\mathcal{C}), \mathcal{O}_{X/S}|_{\mathcal{C}})$$

To see this we will use Sites, Lemma 7.15.5. Note that \mathcal{C} has fibre products and u commutes with them so the categories $\mathcal{I}_{(U, T, \delta)}^u$ are disjoint unions of directed categories (by Sites, Lemma 7.5.1 and Categories, Lemma 4.19.7). Hence it suffices to show that $\mathcal{I}_{(U, T, \delta)}^u$ is connected. Nonempty follows from Lemma 45.5.6 and connectedness follows from the fact that \mathcal{C} has products and that u commutes with them (compare with the proof of Sites, Lemma 7.5.2).

Note that $f_*\mathcal{F} = \mathcal{F}|_{\mathcal{C}}$. Hence the lemma follows if $R^p f_*\mathcal{F} = 0$ for $p > 0$, see Cohomology on Sites, Lemma 21.14.6. By Cohomology on Sites, Lemma 21.8.4 it suffices to show that $H^p((X, T, \delta), \mathcal{F}) = 0$ for all (X, T, δ) . This follows from Lemma 45.18.1. \square

Lemma 45.18.3. *In Situation 45.5.1. Set $\mathcal{C} = (\text{Cris}(C/A))^{opp}$ and $\mathcal{C}^\wedge = (\text{Cris}^\wedge(C/A))^{opp}$ endowed with the chaotic topology, see Remark 45.5.4 for notation. There is a morphism of topoi*

$$g : \text{Sh}(\mathcal{C}) \longrightarrow \text{Sh}(\mathcal{C}^\wedge)$$

such that if \mathcal{F} is a sheaf of abelian groups on \mathcal{C} , then

$$R^p g_*\mathcal{F}(B \rightarrow C, \delta) = \begin{cases} \lim_e \mathcal{F}(B_e \rightarrow C, \delta) & \text{if } p = 0 \\ R^1 \lim_e \mathcal{F}(B_e \rightarrow C, \delta) & \text{if } p = 1 \\ 0 & \text{else} \end{cases}$$

where $B_e = B/p^e B$ for $e \gg 0$.

Proof. Any functor between categories defines a morphism between chaotic topoi in the same direction, for example because such a functor can be considered as a cocontinuous functor between sites, see Sites, Section 7.20. Proof of the description of $g_*\mathcal{F}$ is omitted. Note that in the statement we take $(B_e \rightarrow C, \delta)$ is an object of $\text{Cris}(C/A)$ only for e large enough. Let \mathcal{I} be an injective abelian sheaf on \mathcal{C} . Then the transition maps

$$\mathcal{I}(B_e \rightarrow C, \delta) \leftarrow \mathcal{I}(B_{e+1} \rightarrow C, \delta)$$

are surjective as the morphisms

$$(B_e \rightarrow C, \delta) \longrightarrow (B_{e+1} \rightarrow C, \delta)$$

are monomorphisms in the category \mathcal{C} . Hence for an injective abelian sheaf both sides of the displayed formula of the lemma agree. Taking an injective resolution of \mathcal{F} one easily obtains the result (sheaves are presheaves, so exactness is measured on the level of groups of sections over objects). \square

Lemma 45.18.4. *Let \mathcal{C} be a category endowed with the chaotic topology. Let X be an object of \mathcal{C} such that every object of \mathcal{C} has a morphism towards X . Assume that \mathcal{C} has products. Then for every abelian sheaf \mathcal{F} on \mathcal{C} the total cohomology $R\Gamma(\mathcal{C}, \mathcal{F})$ is represented by the complex*

$$\mathcal{F}(X) \rightarrow \mathcal{F}(X \times X) \rightarrow \mathcal{F}(X \times X \times X) \rightarrow \dots$$

associated to the cosimplicial abelian group $[n] \mapsto \mathcal{F}(X^n)$.

Proof. Note that $H^q(X^p, \mathcal{F}) = 0$ for all $q > 0$ as sheaves are presheaves on \mathcal{C} . The assumption on X is that $h_X \rightarrow *$ is surjective. Using that $H^q(X, \mathcal{F}) = H^p(h_X, \mathcal{F})$ and $H^p(\mathcal{C}, \mathcal{F}) = H^p(*, \mathcal{F})$ we see that our statement is a special case of Cohomology on Sites, Lemma 21.13.2. \square

45.19. Cosimplicial preparations

In this section we compare crystalline cohomology with de Rham cohomology. We follow [BdJ11].

Example 45.19.1. Suppose that A_* is any cosimplicial ring. Consider the cosimplicial module M_* defined by the rule

$$M_n = \bigoplus_{i=0, \dots, n} A_n e_i$$

For a map $f : [n] \rightarrow [m]$ define $M_*(f) : M_n \rightarrow M_m$ to be the unique $A_*(f)$ -linear map which maps e_i to $e_{f(i)}$. We claim the identity on M_* is homotopic to 0. Namely, a homotopy is given by a map of cosimplicial modules

$$h : M_* \longrightarrow \text{Hom}(\Delta[1], M_*)$$

see Section 45.16. For $j \in \{0, \dots, n + 1\}$ we let $\alpha_j^n : [n] \rightarrow [1]$ be the map defined by $\alpha_j^n(i) = 0 \Leftrightarrow i < j$. Then $\Delta[1]_n = \{\alpha_0^n, \dots, \alpha_{n+1}^n\}$ and correspondingly $\text{Hom}(\Delta[1], M_*)_n = \prod_{j=0, \dots, n+1} M_n$, see Simplicial, Sections 14.25 and 14.27. Instead of using this product representation, we think of an element in $\text{Hom}(\Delta[1], M_*)_n$ as a function $\Delta[1]_n \rightarrow M_n$. Using this notation, we define h in degree n by the rule

$$h_n(e_i)(\alpha_j^n) = \begin{cases} e_i & \text{if } i < j \\ 0 & \text{else} \end{cases}$$

We first check h is a morphism of cosimplicial modules. Namely, for $f : [n] \rightarrow [m]$ we will show that

$$(45.19.1.1) \quad h_m \circ M_*(f) = \text{Hom}(\Delta[1], M_*)(f) \circ h_n$$

The left hand side of (45.19.1.1) evaluated at e_i and then in turn evaluated at α_j^m is

$$h_m(e_{f(i)})(\alpha_j^m) = \begin{cases} e_{f(i)} & \text{if } f(i) < j \\ 0 & \text{else} \end{cases}$$

Note that $\alpha_j^m \circ f = \alpha_{j'}^n$, where $0 \leq j' \leq n + 1$ is the unique index such that $f(i) < j$ if and only if $i < j'$. Thus the right hand side of (45.19.1.1) evaluated at e_i and then in turn evaluated at α_j^m is

$$M_*(f)(h_n(e_i)(\alpha_j^m \circ f)) = M_*(f)(h_n(e_i)(\alpha_{j'}^n)) = \begin{cases} e_{f(i)} & \text{if } i < j' \\ 0 & \text{else} \end{cases}$$

It follows from our description of j' that the two answers are equal. Hence h is a map of cosimplicial modules. Let $0 : \Delta[0] \rightarrow \Delta[1]$ and $1 : \Delta[0] \rightarrow \Delta[1]$ be the obvious maps, and denote $ev_0, ev_1 : \text{Hom}(\Delta[1], M_*) \rightarrow M_*$ the corresponding evaluation maps. The reader verifies readily that the compositions

$$ev_0 \circ h, ev_1 \circ h : M_* \longrightarrow M_*$$

are 0 and 1 respectively, whence h is the desired homotopy between 0 and 1.

Lemma 45.19.2. *With notation as in (45.17.0.5) the complex*

$$\Omega_{D(0)} \rightarrow \Omega_{D(1)} \rightarrow \Omega_{D(2)} \rightarrow \dots$$

is homotopic to zero as a $D()$ -cosimplicial module.*

Proof. We are going to use the principle of Simplicial, Lemma 14.27.3 and more specifically Lemma 45.16.1 which tells us that homotopic maps between (co)simplicial objects are transformed by any functor into homotopic maps. The complex of the lemma is equal to the p -adic completion of the base change of the cosimplicial module

$$M_* = (\Omega_{P/A} \rightarrow \Omega_{P \otimes_A P/A} \rightarrow \Omega_{P \otimes_A P \otimes_A P/A} \rightarrow \dots)$$

via the cosimplicial ring map $P \otimes_A \dots \otimes_A P \rightarrow D(n)$. This follows from Lemma 45.6.6, see comments following (45.17.0.2). Hence it suffices to show that the cosimplicial module M_* is homotopic to zero (uses base change and p -adic completion). We can even assume $A = \mathbf{Z}$ and $P = \mathbf{Z}[\{x_i\}_{i \in I}]$ as we can use base change with $\mathbf{Z} \rightarrow A$. In this case $P^{\otimes n+1}$ is the polynomial algebra on the elements

$$x_i(e) = 1 \otimes \dots \otimes x_i \otimes \dots \otimes 1$$

with x_i in the i th slot. The modules of the complex are free on the generators $dx_i(e)$. Note that if $f : [n] \rightarrow [m]$ is a map then we see that

$$M_*(f)(dx_i(e)) = dx_i(f(e))$$

Hence we see that M_* is a direct sum over I of copies of the module studied in Example 45.19.1 and we win. □

Lemma 45.19.3. *With notation as in (45.17.0.4) and (45.17.0.5), given any cosimplicial module M_* over $D(*)$ and $i > 0$ the cosimplicial module*

$$M_0 \otimes_{D(0)}^\wedge \Omega_{D(0)}^i \rightarrow M_1 \otimes_{D(1)}^\wedge \Omega_{D(1)}^i \rightarrow M_2 \otimes_{D(2)}^\wedge \Omega_{D(2)}^i \rightarrow \dots$$

is homotopic to zero, where $\Omega_{D(n)}^i$ is the p -adic completion of the i th exterior power of $\Omega_{D(n)}$.

Proof. By Lemma 45.19.2 the endomorphisms 0 and 1 of $\Omega_{D(*)}$ are homotopic. If we apply the functor \wedge^i we see that the same is true for the cosimplicial module $\wedge^i \Omega_{D(*)}$, see Lemma 45.16.1. Another application of the same lemma shows the p -adic completion $\Omega_{D(*)}^i$ is homotopy equivalent to zero. Tensoring with M_* we see that $M_* \otimes_{D(*)} \Omega_{D(*)}^i$ is homotopic to zero, see Lemma 45.16.1 again. A final application of the p -adic completion functor finishes the proof. □

45.20. Divided power Poincaré lemma

Just the simplest possible version.

Lemma 45.20.1. *Let A be a ring. Let $P = A\langle x_i \rangle$ be a divided power polynomial ring over A . For any A -module M the complex*

$$0 \rightarrow M \rightarrow M \otimes_A P \rightarrow M \otimes_A \Omega_{P/A,\delta}^1 \rightarrow M \otimes_A \Omega_{P/A,\delta}^2 \rightarrow \dots$$

is exact. Let D be the p -adic completion of P . Let Ω_D^i be the p -adic completion of the i th exterior power of $\Omega_{D/A,\delta}$. For any p -adically complete A -module M the complex

$$0 \rightarrow M \rightarrow M \otimes_A^\wedge D \rightarrow M \otimes_A^\wedge \Omega_D^1 \rightarrow M \otimes_A^\wedge \Omega_D^2 \rightarrow \dots$$

is exact.

Proof. It suffices to show that the complex

$$E : (0 \rightarrow A \rightarrow P \rightarrow \Omega_{P/A,\delta}^1 \rightarrow \Omega_{P/A,\delta}^2 \rightarrow \dots)$$

is homotopy equivalent to zero as a complex of A -modules. For every multi-index $K = (k_i)$ we can consider the subcomplex $E(K)$ which in degree j consists of

$$\bigoplus_{I=\{i_1, \dots, i_j\} \subset \text{Supp}(K)} A \prod_{i \notin I} x_i^{[k_i]} \prod_{i \in I} x_i^{[k_i-1]} dx_{i_1} \wedge \dots \wedge dx_{i_j}$$

Since $E = \bigoplus E(K)$ we see that it suffices to prove each of the complexes $E(K)$ is homotopic to zero. If $K = 0$, then $E(K) : (A \rightarrow A)$ is homotopic to zero. If K has nonempty (finite) support S , then the complex $E(K)$ is isomorphic to the complex

$$0 \rightarrow A \rightarrow \bigoplus_{s \in S} A \rightarrow \wedge^2 \left(\bigoplus_{s \in S} A \right) \rightarrow \dots \rightarrow \wedge^{\#S} \left(\bigoplus_{s \in S} A \right) \rightarrow 0$$

which is homotopic to zero, for example by More on Algebra, Lemma 15.20.5. \square

An alternative (more direct) approach to the following lemma is explained in Example 45.25.2.

Lemma 45.20.2. *Let A be a ring. Let (B, J, δ) be a divided power ring. Let $P = B\langle x_i \rangle$ be a divided power polynomial ring over B with divided power ideal $J = IP + B\langle x_i \rangle_+$ as usual. Let M be a B -module endowed with an integrable connection $\nabla : M \rightarrow M \otimes_B \Omega_{B/A,\delta}^1$. Then the map of de Rham complexes*

$$M \otimes_B \Omega_{B/A,\delta}^* \longrightarrow M \otimes_P \Omega_{P/A,\delta}^*$$

is a quasi-isomorphism. Let D , resp. D' be the p -adic completion of B , resp. P and let Ω_D^i , resp. $\Omega_{D'}^i$ be the p -adic completion of $\Omega_{B/A,\delta}^i$, resp. $\Omega_{P/A,\delta}^i$. Let M be a p -adically complete D -module endowed with an integral connection $\nabla : M \rightarrow M \otimes_D^\wedge \Omega_D^1$. Then the map of de Rham complexes

$$M \otimes_D^\wedge \Omega_D^* \longrightarrow M \otimes_{D'}^\wedge \Omega_{D'}^*$$

is a quasi-isomorphism.

Proof. Consider the decreasing filtration F^* on $\Omega_{B/A,\delta}^*$ given by the subcomplexes $F^i(\Omega_{B/A,\delta}^*) = \sigma_{\geq i} \Omega_{B/A,\delta}^*$. See Homology, Section 12.13. This induces a decreasing filtration F^* on $\Omega_{P/A,\delta}^*$ by setting

$$F^i(\Omega_{P/A,\delta}^*) = F^i(\Omega_{B/A,\delta}^*) \wedge \Omega_{P/A,\delta}^*$$

We have a split short exact sequence

$$0 \rightarrow \Omega_{B/A,\delta}^1 \otimes_B P \rightarrow \Omega_{P/A,\delta}^1 \rightarrow \Omega_{P/B,\delta}^1 \rightarrow 0$$

and the last module is free on dx_i . It follows from this that $F^i(\Omega_{P/A,\delta}^*) \rightarrow \Omega_{P/A,\delta}^*$ is a termwise split injection and that

$$\mathrm{gr}_F^i(\Omega_{B/A,\delta}^*) = \Omega_{B/A,\delta}^i \otimes_B \Omega_{P/B,\delta}^*$$

as complexes. Thus we can define a filtration F^* on $M \otimes_B \Omega_{B/A,\delta}^*$ by setting

$$F^i(M \otimes_B \Omega_{P/A,\delta}^*) = M \otimes_B F^i(\Omega_{P/A,\delta}^*)$$

and we have

$$\mathrm{gr}_F^i(M \otimes_B \Omega_{P/A,\delta}^*) = M \otimes_B \Omega_{B/A,\delta}^i \otimes_B \Omega_{P/B,\delta}^*$$

as complexes. By Lemma 45.20.1 each of these complexes is quasi-isomorphic to $M \otimes_B \Omega_{B/A,\delta}^i$ placed in degree 0. Hence we see that the first displayed map of the lemma is a morphism of filtered complexes which induces a quasi-isomorphism on graded pieces. This implies that it is a quasi-isomorphism, for example by the spectral sequence associated to a filtered complex, see Homology, Section 12.21.

The proof of the second quasi-isomorphism is exactly the same. □

45.21. Cohomology in the affine case

Let's go back to the situation studied in Section 45.17. We start with (A, I, γ) and $A/I \rightarrow C$ and set $X = \mathrm{Spec}(C)$ and $S = \mathrm{Spec}(A)$. Then we choose a polynomial ring P over A and a surjection $P \rightarrow C$ with kernel J . We obtain D and $D(n)$ see (45.17.0.1) and (45.17.0.4). Set $T(n)_e = \mathrm{Spec}(D(n)/p^e D(n))$ so that $(X, T(n)_e, \delta(n))$ is an object of $\mathrm{Cris}(X/S)$. Let \mathcal{F} be a sheaf of $\mathcal{O}_{X/S}$ -modules and set

$$M(n) = \lim_e \Gamma((X, T(n)_e, \delta(n)), \mathcal{F})$$

for $n = 0, 1, 2, 3, \dots$. This forms a cosimplicial module over the cosimplicial ring $D(0), D(1), D(2), \dots$

Proposition 45.21.1. *With notations as above assume that*

- (1) \mathcal{F} is locally quasi-coherent, and
- (2) for any morphism $(U, T, \delta) \rightarrow (U', T', \delta')$ of $\mathrm{Cris}(X/S)$ where $f : T \rightarrow T'$ is a closed immersion the map $c_f : f^* \mathcal{F}_{T'} \rightarrow \mathcal{F}_T$ is surjective.

Then the complex

$$M(0) \rightarrow M(1) \rightarrow M(2) \rightarrow \dots$$

computes $R\Gamma(\mathrm{Cris}(X/S), \mathcal{F})$.

Proof. Using assumption (1) and Lemma 45.18.2 we see that $R\Gamma(\mathrm{Cris}(X/S), \mathcal{F})$ is isomorphic to $R\Gamma(\mathcal{C}, \mathcal{F})$. Note that the categories \mathcal{C} used in Lemmas 45.18.2 and 45.18.3 agree. Let $f : T \rightarrow T'$ be a closed immersion as in (2). Surjectivity of $c_f : f^* \mathcal{F}_{T'} \rightarrow \mathcal{F}_T$ is equivalent to surjectivity of $\mathcal{F}_{T'} \rightarrow f_* \mathcal{F}_T$. Hence, if \mathcal{F} satisfies (1) and (2), then we obtain a short exact sequence

$$0 \rightarrow \mathcal{K} \rightarrow \mathcal{F}_{T'} \rightarrow f_* \mathcal{F}_T \rightarrow 0$$

of quasi-coherent $\mathcal{O}_{T'}$ -modules on T' , see Schemes, Section 25.24 and in particular Lemma 25.24.1. Thus, if T' is affine, then we conclude that the restriction map $\mathcal{F}(U', T', \delta') \rightarrow \mathcal{F}(U, T, \delta)$ is surjective by the vanishing of $H^1(T', \mathcal{K})$, see Cohomology of Schemes, Lemma 29.2.2. Hence the transition maps of the inverse systems in

Lemma 45.18.3 are surjective. We conclude that that $R^p g_*(\mathcal{F}|_{\mathcal{C}}) = 0$ for all $p \geq 1$ where g is as in Lemma 45.18.3. The object D of the category \mathcal{C}^\wedge satisfies the assumption of Lemma 45.18.4 by Lemma 45.5.7 with

$$D \times \dots \times D = D(n)$$

in \mathcal{C} because $D(n)$ is the $n + 1$ -fold coproduct of D in $\text{Cris}^\wedge(C/A)$, see Lemma 45.17.2. Thus we win. \square

Lemma 45.21.2. *Assumptions and notation as in Proposition 45.21.1. Then*

$$H^j(\text{Cris}(X/S), \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^i) = 0$$

for all $i > 0$ and all $j \geq 0$.

Proof. Using Lemma 45.12.6 it follows that $\mathcal{H} = \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^i$ also satisfies assumptions (1) and (2) of Proposition 45.21.1. Write $M(n)_e = \Gamma((X, T(n)_e, \delta(n)), \mathcal{F})$ so that $M(n) = \lim_e M(n)_e$. Then

$$\begin{aligned} \lim_e \Gamma((X, T(n)_e, \delta(n)), \mathcal{H}) &= \lim_e M(n)_e \otimes_{D(n)_e} \Omega_{D(n)} / p^e \Omega_{D(n)} \\ &= \lim_e M(n)_e \otimes_{D(n)} \Omega_{D(n)} \end{aligned}$$

By Lemma 45.19.3 the cosimplicial modules

$$M(0)_e \otimes_{D(0)} \Omega_{D(0)}^i \rightarrow M(1)_e \otimes_{D(1)} \Omega_{D(1)}^i \rightarrow M(2)_e \otimes_{D(2)} \Omega_{D(2)}^i \rightarrow \dots$$

are homotopic to zero. Because the transition maps $M(n)_{e+1} \rightarrow M(n)_e$ are surjective, we see that the inverse limit of the associated complexes are acyclic⁵. Hence the vanishing of cohomology of \mathcal{H} by Proposition 45.21.1. \square

Proposition 45.21.3. *Assumptions as in Proposition 45.21.1 but now assume that \mathcal{F} is a crystal in quasi-coherent modules. Let (M, ∇) be the corresponding module with connection over D , see Proposition 45.17.4. Then the complex*

$$M \otimes_D^\wedge \Omega_D^*$$

computes $R\Gamma(\text{Cris}(X/S), \mathcal{F})$.

Proof. We will prove this using the two spectral sequences associated to the double complex $K^{*,*}$ with terms

$$K^{a,b} = M \otimes_D^\wedge \Omega_{D(b)}^a$$

What do we know so far? Well, Lemma 45.19.3 tells us that each column $K^{a,*}$, $a > 0$ is acyclic. Proposition 45.21.1 tells us that the first column $K^{0,*}$ is quasi-isomorphic to $R\Gamma(\text{Cris}(X/S), \mathcal{F})$. Hence the first spectral sequence associated to the double complex shows that there is a canonical quasi-isomorphism of $R\Gamma(\text{Cris}(X/S), \mathcal{F})$ with $\text{Tot}(K^{*,*})$.

Next, let's consider the rows $K^{*,b}$. By Lemma 45.17.1 each of the $b + 1$ maps $D \rightarrow D(b)$ presents $D(b)$ as the p -adic completion of a divided power polynomial algebra over D . Hence Lemma 45.20.2 shows that the map

$$M \otimes_D^\wedge \Omega_D^* \longrightarrow M \otimes_{D(b)}^\wedge \Omega_{D(b)}^* = K^{*,b}$$

⁵Actually, they are even homotopic to zero as the homotopies fit together, but we don't need this. The reason for this roundabout argument is that the limit $\lim_e M(n)_e \otimes_{D(n)} \Omega_{D(n)}^i$ isn't the p -adic completion of $M(n) \otimes_{D(n)} \Omega_{D(n)}^i$ as with the assumptions of the lemma we don't know that $M(n)_e = M(n)_{e+1}/p^e M(n)_{e+1}$. If \mathcal{F} is a crystal then this does hold.

is a quasi-isomorphism. Note that each of these maps defines the *same* map on cohomology (and even the same map in the derived category) as the inverse is given by the co-diagonal map $D(b) \rightarrow D$ (corresponding to the multiplication map $P \otimes_A \dots \otimes_A P \rightarrow P$). Hence if we look at the E_1 page of the second spectral sequence we obtain

$$E_1^{a,b} = H^a(M \otimes_D^{\wedge} \Omega_D^*)$$

with differentials

$$E_1^{a,0} \xrightarrow{0} E_1^{a,1} \xrightarrow{1} E_1^{a,2} \xrightarrow{0} E_1^{a,3} \xrightarrow{1} \dots$$

as each of these is the alternation sum of the given identifications $H^a(M \otimes_D^{\wedge} \Omega_D^*) = E_1^{a,0} = E_1^{a,1} = \dots$. Thus we see that the E_2 page is equal $H^a(M \otimes_D^{\wedge} \Omega_D^*)$ on the first row and zero elsewhere. It follows that the identification of $M \otimes_D^{\wedge} \Omega_D^*$ with the first row induces a quasi-isomorphism of $M \otimes_D^{\wedge} \Omega_D^*$ with $\text{Tot}(K^{*,*})$. \square

Lemma 45.21.4. *Assumptions as in Proposition 45.21.3. Let $A \rightarrow P' \rightarrow C$ be ring maps with $A \rightarrow P'$ smooth and $P' \rightarrow C$ surjective with kernel J' . Let D' be the p -adic completion of $D_{P',\gamma}(J')$. Let (M', ∇') be the pair over D' corresponding to \mathcal{F} , see Lemma 45.17.5. Then the complex*

$$M' \otimes_{D'}^{\wedge} \Omega_{D'}^*$$

computes $R\Gamma(\text{Cris}(X/S), \mathcal{F})$.

Proof. Choose $a : D \rightarrow D'$ and $b : D' \rightarrow D$ as in Lemma 45.17.5. Note that the base change $M = M' \otimes_{D',b} D$ with its connection ∇ corresponds to \mathcal{F} . Hence we know that $M \otimes_D^{\wedge} \Omega_D^*$ computes the crystalline cohomology of \mathcal{F} , see Proposition 45.21.3. Hence it suffices to show that the base change maps (induced by a and b)

$$M' \otimes_{D'}^{\wedge} \Omega_{D'}^* \longrightarrow M \otimes_D^{\wedge} \Omega_D^* \quad \text{and} \quad M \otimes_D^{\wedge} \Omega_D^* \longrightarrow M' \otimes_{D'}^{\wedge} \Omega_{D'}^*$$

are quasi-isomorphisms. Since $a \circ b = \text{id}_{D'}$ we see that the composition one way around is the identity on the complex $M' \otimes_{D'}^{\wedge} \Omega_{D'}^*$. Hence it suffices to show that the map

$$M \otimes_D^{\wedge} \Omega_D^* \longrightarrow M \otimes_{D'}^{\wedge} \Omega_{D'}^*$$

induced by $b \circ a : D \rightarrow D'$ is a quasi-isomorphism. (Note that we have the same complex on both sides as $M = M' \otimes_{D',b} D$, hence $M \otimes_{D',b \circ a} D = M' \otimes_{D',b \circ a \circ b} D = M' \otimes_{D',b} D = M$.) In fact, we claim that for any divided power A -algebra homomorphism $\rho : D \rightarrow D'$ compatible with the augmentation to C the induced map $M \otimes_D^{\wedge} \Omega_D^* \rightarrow M \otimes_{D',\rho}^{\wedge} \Omega_{D'}^*$ is a quasi-isomorphism.

Write $\rho(x_i) = x_i + z_i$. The elements z_i are in the divided power ideal of D because ρ is compatible with the augmentation to C . Hence we can factor the map ρ as a composition

$$D \xrightarrow{\sigma} D\langle \xi_i \rangle^{\wedge} \xrightarrow{\tau} D$$

where the first map is given by $x_i \mapsto x_i + \xi_i$ and the second map is the divided power D -algebra map which maps ξ_i to z_i . (This uses the universal properties of polynomial algebra, divided power polynomial algebras, divided power envelopes, and p -adic completion.) Note that there exists an *automorphism* α of $D\langle \xi_i \rangle^{\wedge}$ with $\alpha(x_i) = x_i - \xi_i$ and $\alpha(\xi_i) = \xi_i$. Applying Lemma 45.20.2 to $\alpha \circ \sigma$ (which maps x_i to x_i) and using that α is an isomorphism we conclude that σ induces a quasi-isomorphism of $M \otimes_D^{\wedge} \Omega_D^*$ with $M \otimes_{D',\sigma}^{\wedge} \Omega_{D\langle \xi_i \rangle^{\wedge}}^*$. On the other hand the map τ has as a left inverse the map $D \rightarrow D\langle x_i \rangle^{\wedge}$, $x_i \mapsto x_i$ and we conclude (using Lemma

45.20.2 once more) that τ induces a quasi-isomorphism of $M \otimes_{D,\sigma}^{\wedge} \Omega_{D(x_i)^\wedge}^*$ with $M \otimes_{D,\tau \circ \sigma}^{\wedge} \Omega_D^*$. Composing these two quasi-isomorphisms we obtain that ρ induces a quasi-isomorphism $M \otimes_D^{\wedge} \Omega_D^* \rightarrow M \otimes_{D,\rho}^{\wedge} \Omega_D^*$ as desired. \square

45.22. Two counter examples

Before we turn to some of the successes of crystalline cohomology, let us give two examples which explain why crystalline cohomology does not work very well if the schemes in question are either not proper over the base, or singular. The first example can be found in [BO83].

Example 45.22.1. Let $A = \mathbf{Z}_p$ with divided power ideal (p) endowed with its unique divided powers γ . Let $C = \mathbf{F}_p[x, y]/(x^2, xy, y^2)$. We choose the presentation

$$C = P/J = \mathbf{Z}_p[x, y]/(x^2, xy, y^2, p)$$

Let $D = D_{P,\gamma}(J)^\wedge$ with divided power ideal $(\bar{J}, \bar{\gamma})$ as in Section 45.17. We will denote x, y also the images of x and y in D . Consider the element

$$\tau = \bar{\gamma}_p(x^2)\bar{\gamma}_p(y^2) - \bar{\gamma}_p(xy)^2 \in D$$

We note that $p\tau = 0$ as

$$p!\bar{\gamma}_p(x^2)\bar{\gamma}_p(y^2) = x^{2p}\bar{\gamma}_p(y^2) = \bar{\gamma}_p(x^2y^2) = x^py^p\bar{\gamma}_p(xy) = p!\bar{\gamma}_p(xy)^2$$

in D . We also note that $d\tau = 0$ in Ω_D as

$$\begin{aligned} d(\bar{\gamma}_p(x^2)\bar{\gamma}_p(y^2)) &= \bar{\gamma}_{p-1}(x^2)\bar{\gamma}_p(y^2)dx^2 + \bar{\gamma}_p(x^2)\bar{\gamma}_{p-1}(y^2)dy^2 \\ &= 2x\bar{\gamma}_{p-1}(x^2)\bar{\gamma}_p(y^2)dx + 2y\bar{\gamma}_p(x^2)\bar{\gamma}_{p-1}(y^2)dy \\ &= 2/(p-1)!(x^{2p-1}\bar{\gamma}_p(y^2)dx + y^{2p-1}\bar{\gamma}_p(x^2)dy) \\ &= 2/(p-1)!(x^{p-1}\bar{\gamma}_p(xy^2)dx + y^{p-1}\bar{\gamma}_p(x^2y)dy) \\ &= 2/(p-1)!(x^{p-1}y^p\bar{\gamma}_p(xy)dx + x^py^{p-1}\bar{\gamma}_p(xy)dy) \\ &= 2\bar{\gamma}_{p-1}(xy)\bar{\gamma}_p(xy)(ydx + xdy) \\ &= d(\bar{\gamma}_p(xy)^2) \end{aligned}$$

Finally, we claim that $\tau \neq 0$ in D . To see this it suffices to produce an object $(B \rightarrow \mathbf{F}_p[x, y]/(x^2, xy, y^2), \delta)$ of $\text{Cris}(C/S)$ such that τ does not map to zero in B . To do this take

$$B = \mathbf{F}_p[x, y, u, v]/(x^3, x^2y, xy^2, y^3, xu, yu, xv, yv, u^2, v^2)$$

with the obvious surjection to C . Let $K = \text{Ker}(B \rightarrow C)$ and consider the map

$$\delta_p : K \longrightarrow K, \quad ay^2 + bxy + cy^2 + du + ev + fuv \longmapsto a^pu + c^pv$$

One checks this satisfies the assumptions (1), (2), (3) of Divided Power Algebra, Lemma 23.5.3 and hence defines a divided power structure. Moreover, we see that τ maps to uv which is not zero in B . Set $X = \text{Spec}(C)$ and $S = \text{Spec}(A)$. We draw the following conclusions

- (1) $H^0(\text{Cris}(X/S), \mathcal{O}_{X/S})$ has p -torsion, and
- (2) pulling back by Frobenius $F^* : H^0(\text{Cris}(X/S), \mathcal{O}_{X/S}) \rightarrow H^0(\text{Cris}(X/S), \mathcal{O}_{X/S})$ is not injective.

Namely, τ defines a nonzero torsion element of $H^0(\text{Cris}(X/S), \mathcal{O}_{X/S})$ by Proposition 45.21.3. Similarly, $F^*(\tau) = \sigma(\tau)$ where $\sigma : D \rightarrow D$ is the map induced by any lift of Frobenius on P . If we choose $\sigma(x) = x^p$ and $\sigma(y) = y^p$, then an easy computation shows that $F^*(\tau) = 0$.

The next example shows that even for affine n -space crystalline cohomology does not give the correct thing.

Example 45.22.2. Let $A = \mathbf{Z}_p$ with divided power ideal (p) endowed with its unique divided powers γ . Let $C = \mathbf{F}_p[x_1, \dots, x_r]$. We choose the presentation

$$C = P/J = P/pP \quad \text{with} \quad P = \mathbf{Z}_p[x_1, \dots, x_r]$$

Note that pP has divided powers by Divided Power Algebra, Lemma 23.4.2. Hence setting $D = P^\wedge$ with divided power ideal (p) we obtain a situation as in Section 45.17. We conclude that $R\Gamma(\text{Cris}(X/S), \mathcal{O}_{X/S})$ is represented by the complex

$$D \rightarrow \Omega_D^1 \rightarrow \Omega_D^2 \rightarrow \dots \rightarrow \Omega_D^r$$

see Proposition 45.21.3. Assuming $r > 0$ we conclude the following

- (1) The crystalline cohomology of the crystalline structure sheaf of $X = \mathbf{A}_{\mathbf{F}_p}^r$ over $S = \text{Spec}(\mathbf{Z}_p)$ is zero except in degrees $0, \dots, r$.
- (2) We have $H^0(\text{Cris}(X/S), \mathcal{O}_{X/S}) = \mathbf{Z}_p$.
- (3) The cohomology group $H^r(\text{Cris}(X/S), \mathcal{O}_{X/S})$ is infinite and is not a torsion abelian group.
- (4) The cohomology group $H^r(\text{Cris}(X/S), \mathcal{O}_{X/S})$ is not separated for the p -adic topology.

While the first two statements are reasonable, parts (3) and (4) are disconcerting! The truth of these statements follows immediately from working out what the complex displayed above looks like. Let's just do this in case $r = 1$. Then we are just looking at the two term complex of p -adically complete modules

$$d : D = \left(\bigoplus_{n \geq 0} \mathbf{Z}_p x^n \right)^\wedge \longrightarrow \Omega_D^1 = \left(\bigoplus_{n \geq 1} \mathbf{Z}_p x^{n-1} dx \right)^\wedge$$

The map is given by $\text{diag}(0, 1, 2, 3, 4, \dots)$ except that the first summand is missing on the right hand side. Now it is clear that $\bigoplus_{n > 0} \mathbf{Z}_p/n\mathbf{Z}_p$ is a subgroup of the cokernel, hence the cokernel is infinite. In fact, the element

$$\omega = \sum_{e > 0} p^e x^{p^{2e}-1} dx$$

is clearly not a torsion element of the cokernel. But it gets worse. Namely, consider the element

$$\eta = \sum_{e > 0} p^e x^{p^e-1} dx$$

For every $t > 0$ the element η is congruent to $\sum_{e > t} p^e x^{p^e-1} dx$ modulo the image of d which is divisible by p^t . But η is not in the image of d because it would have to be the image of $a + \sum_{e > 0} x^{p^e}$ for some $a \in \mathbf{Z}_p$ which is not an element of the left hand side. In fact, $p^N \eta$ is similarly not in the image of d for any integer N . This implies that η "generates" a copy of \mathbf{Q}_p inside of $H_{\text{cris}}^1(\mathbf{A}_{\mathbf{F}_p}^1/\text{Spec}(\mathbf{Z}_p))$.

45.23. Applications

In this section we collect some applications of the material in the previous sections.

Proposition 45.23.1. *In Situation 45.7.5. Let \mathcal{F} be a crystal in quasi-coherent modules on $\mathrm{Cris}(X/S)$. The truncation map of complexes*

$$(\mathcal{F} \rightarrow \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^1 \rightarrow \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^2 \rightarrow \dots) \longrightarrow \mathcal{F}[0],$$

while not a quasi-isomorphism, becomes a quasi-isomorphism after applying $Ru_{X/S,}$. In fact, for any $i > 0$, we have*

$$Ru_{X/S,*}(\mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^i) = 0.$$

Proof. By Lemma 45.15.1 we get a de Rham complex as indicated in the lemma. We abbreviate $\mathcal{H} = \mathcal{F} \otimes \Omega_{X/S}^i$. Let $X' \subset X$ be an affine open subscheme which maps into an affine open subscheme $S' \subset S$. Then

$$(Ru_{X/S,*}\mathcal{H})|_{X'_{Zar}} = Ru_{X'/S',*}(\mathcal{H}|_{\mathrm{Cris}(X'/S')}),$$

see Lemma 45.9.5. Thus Lemma 45.21.2 shows that $Ru_{X/S,*}\mathcal{H}$ is a complex of sheaves on X_{Zar} whose cohomology on any affine open is trivial. As X has a basis for its topology consisting of affine opens this implies that $Ru_{X/S,*}\mathcal{H}$ is quasi-isomorphic to zero. \square

Remark 45.23.2. The proof of Proposition 45.23.1 shows that the conclusion

$$Ru_{X/S,*}(\mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^i) = 0$$

for $i > 0$ is true for any $\mathcal{O}_{X/S}$ -module \mathcal{F} which satisfies conditions (1) and (2) of Proposition 45.21.1. This applies to the following non-crystals: $\Omega_{X/S}^i$ for all i , and any sheaf of the form $\underline{\mathcal{F}}$, where \mathcal{F} is a quasi-coherent \mathcal{O}_X -module. In particular, it applies to the sheaf $\underline{\mathcal{O}_X} = \underline{\mathbf{G}}_a$. But note that we need something like Lemma 45.15.1 to produce a de Rham complex which requires \mathcal{F} to be a crystal. Hence (currently) the collection of sheaves of modules for which the full statement of Proposition 45.23.1 holds is exactly the category of crystals in quasi-coherent modules.

In Situation 45.7.5. Let \mathcal{F} be a crystal in quasi-coherent modules on $\mathrm{Cris}(X/S)$. Let (U, T, δ) be an object of $\mathrm{Cris}(X/S)$. Proposition 45.23.1 allows us to construct a canonical map

$$(45.23.2.1) \quad R\Gamma(\mathrm{Cris}(X/S), \mathcal{F}) \longrightarrow R\Gamma(T, \mathcal{F}_T \otimes_{\mathcal{O}_T} \Omega_{T/S, \delta}^*)$$

Namely, we have $R\Gamma(\mathrm{Cris}(X/S), \mathcal{F}) = R\Gamma(\mathrm{Cris}(X/S), \mathcal{F} \otimes \Omega_{X/S}^*)$, we can restrict global cohomology classes to T , and $\Omega_{X/S}$ restricts to $\Omega_{T/S, \delta}$ by Lemma 45.12.3.

45.24. Some further results

In this section we mention some results whose proof is missing. We will formulate these as a series of remarks and we will convert them into actual lemmas and propositions only when we add detailed proofs.

Remark 45.24.1 (Higher direct images). Let p be a prime number. Let $(S, \mathcal{I}, \gamma) \rightarrow (S', \mathcal{I}', \gamma')$ be a morphism of divided power schemes over $\mathbf{Z}_{(p)}$. Let

$$\begin{array}{ccc} X & \xrightarrow{f} & X' \\ \downarrow & & \downarrow \\ S_0 & \longrightarrow & S'_0 \end{array}$$

be a commutative diagram of morphisms of schemes and assume p is locally nilpotent on X and X' . Let \mathcal{F} be an $\mathcal{O}_{X/S}$ -module on $\text{Cris}(X/S)$. Then $Rf_{\text{cris},*}\mathcal{F}$ can be computed as follows.

Given an object (U', T', δ') of $\text{Cris}(X'/S')$ set $U = X \times_{X'} U' = f^{-1}(U')$ (an open subscheme of X). Denote (T_0, T, δ) the divided power scheme over S such that

$$\begin{array}{ccc} T & \longrightarrow & T' \\ \downarrow & & \downarrow \\ S & \longrightarrow & S' \end{array}$$

is cartesian in the category of divided power schemes, see Lemma 45.7.4. There is an induced morphism $U \rightarrow T_0$ and we obtain a morphism $(U/T)_{\text{cris}} \rightarrow (X/S)_{\text{cris}}$, see Remark 45.9.3. Let \mathcal{F}_U be the pullback of \mathcal{F} . Let $\tau_{U/T} : (U/T)_{\text{cris}} \rightarrow T_{\text{Zar}}$ be the structure morphism. Then we have

$$(45.24.1.1) \quad (Rf_{\text{cris},*}\mathcal{F})_{T'} = R(T \rightarrow T')_* (R\tau_{U/T,*}\mathcal{F}_U)$$

where the left hand side is the restriction (see Section 45.10).

Hints: First, show that $\text{Cris}(U/T)$ is the localization (in the sense of Sites, Lemma 7.29.3) of $\text{Cris}(X/S)$ at the sheaf of sets $f_{\text{cris}}^{-1}h_{(U', T', \delta')}$. Next, reduce the statement to the case where \mathcal{F} is an injective module and pushforward of modules using that the pullback of an injective $\mathcal{O}_{X/S}$ -module is an injective $\mathcal{O}_{U/T}$ -module on $\text{Cris}(U/T)$. Finally, check the result holds for plain pushforward.

Remark 45.24.2 (Mayer-Vietoris). In the situation of Remark 45.24.1 suppose we have an open covering $X = X' \cup X''$. Denote $X''' = X' \cap X''$. Let f', f'' , and f''' be the restriction of f to X', X'' , and X''' . Moreover, let $\mathcal{F}', \mathcal{F}''$, and \mathcal{F}''' be the restriction of \mathcal{F} to the crystalline sites of X', X'' , and X''' . Then there exists a distinguished triangle

$$Rf_{\text{cris},*}\mathcal{F} \longrightarrow Rf'_{\text{cris},*}\mathcal{F}' \oplus Rf''_{\text{cris},*}\mathcal{F}'' \longrightarrow Rf'''_{\text{cris},*}\mathcal{F}''' \longrightarrow Rf_{\text{cris},*}\mathcal{F}[1]$$

in $D(\mathcal{O}_{X'/S'})$.

Hints: This is a formal consequence of the fact that the subcategories $\text{Cris}(X'/S)$, $\text{Cris}(X''/S)$, $\text{Cris}(X'''/S)$ correspond to open subobjects of the final sheaf on $\text{Cris}(X/S)$ and that the last is the intersection of the first two.

Remark 45.24.3 (Čech complex). Let p be a prime number. Let (A, I, γ) be a divided power ring with A a $\mathbf{Z}_{(p)}$ -algebra. Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let X be a separated⁶ scheme over S_0 such that p is locally nilpotent on X . Let \mathcal{F} be a crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules.

⁶This assumption is not strictly necessary, as using hypercoverings the construction of the remark can be extended to the general case.

Choose an affine open covering $X = \bigcup_{\lambda \in \Lambda} U_\lambda$ of X . Write $U_\lambda = \text{Spec}(C_\lambda)$. Choose a polynomial algebra P_λ over A and a surjection $P_\lambda \rightarrow C_\lambda$. Having fixed these choices we can construct a Čech complex which computes $R\Gamma(\text{Cris}(X/S), \mathcal{F})$.

Given $n \geq 0$ and $\lambda_0, \dots, \lambda_n \in \Lambda$ write $U_{\lambda_0 \dots \lambda_n} = U_{\lambda_0} \cap \dots \cap U_{\lambda_n}$. This is an affine scheme by assumption. Write $U_{\lambda_0 \dots \lambda_n} = \text{Spec}(C_{\lambda_0 \dots \lambda_n})$. Set

$$P_{\lambda_0 \dots \lambda_n} = P_{\lambda_0} \otimes_A \dots \otimes_A P_{\lambda_n}$$

which comes with a canonical surjection onto $C_{\lambda_0 \dots \lambda_n}$. Denote the kernel $J_{\lambda_0 \dots \lambda_n}$ and set $D_{\lambda_0 \dots \lambda_n}$ the p -adically completed divided power envelope of $J_{\lambda_0 \dots \lambda_n}$ in $P_{\lambda_0 \dots \lambda_n}$ relative to γ . Let $M_{\lambda_0 \dots \lambda_n}$ be the $P_{\lambda_0 \dots \lambda_n}$ -module corresponding to the restriction of \mathcal{F} to $\text{Cris}(U_{\lambda_0 \dots \lambda_n}/S)$ via Proposition 45.17.4. By construction we obtain a cosimplicial divided power ring $D(*)$ having in degree n the ring

$$D(n) = \prod_{\lambda_0 \dots \lambda_n} D_{\lambda_0 \dots \lambda_n}$$

(use that divided power envelopes are functorial and the trivial cosimplicial structure on the ring $P(*)$ defined similarly). Since $M_{\lambda_0 \dots \lambda_n}$ is the “value” of \mathcal{F} on the objects $\text{Spec}(D_{\lambda_0 \dots \lambda_n})$ we see that $M(*)$ defined by the rule

$$M(n) = \prod_{\lambda_0 \dots \lambda_n} M_{\lambda_0 \dots \lambda_n}$$

forms a cosimplicial $D(*)$ -module. Now we claim that we have

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) = s(M(*))$$

Here $s(-)$ denotes the cochain complex associated to a cosimplicial module (see Simplicial, Section 14.24).

Hints: The proof of this is similar to the proof of Proposition 45.21.1 (in particular the result holds for any module satisfying the assumptions of that proposition).

Remark 45.24.4 (Alternating Čech complex). Let p be a prime number. Let (A, I, γ) be a divided power ring with A a $\mathbf{Z}_{(p)}$ -algebra. Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let X be a separated quasi-compact scheme over S_0 such that p is locally nilpotent on X . Let \mathcal{F} be a crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules.

Choose a finite affine open covering $X = \bigcup_{\lambda \in \Lambda} U_\lambda$ of X and a total ordering on Λ . Write $U_\lambda = \text{Spec}(C_\lambda)$. Choose a polynomial algebra P_λ over A and a surjection $P_\lambda \rightarrow C_\lambda$. Having fixed these choices we can construct an alternating Čech complex which computes $R\Gamma(\text{Cris}(X/S), \mathcal{F})$.

We are going to use the notation introduced in Remark 45.24.3. Denote $\Omega_{\lambda_0 \dots \lambda_n}$ the p -adically completed module of differentials of $D_{\lambda_0 \dots \lambda_n}$ over A compatible with the divided power structure. Let ∇ be the integrable connection on $M_{\lambda_0 \dots \lambda_n}$ coming from Proposition 45.17.4. Consider the double complex $M^{\bullet, \bullet}$ with terms

$$M^{n,m} = \bigoplus_{\lambda_0 < \dots < \lambda_n} M_{\lambda_0 \dots \lambda_n} \otimes_{\hat{D}_{\lambda_0 \dots \lambda_n}} \Omega_{D_{\lambda_0 \dots \lambda_n}}^m.$$

For the differential d_1 (increasing n) we use the usual Čech differential and for the differential d_2 we use the connection, i.e., the differential of the de Rham complex. We claim that

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) = \text{Tot}(M^{\bullet, \bullet})$$

Here $\text{Tot}(-)$ denotes the total complex associated to a double complex, see Homology, Definition 12.22.3.

Hints: We have

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) = R\Gamma(\text{Cris}(X/S), \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^\bullet)$$

by Proposition 45.23.1. The right hand side of the formula is simply the alternating Čech complex for the covering $X = \bigcup_{\lambda \in \Lambda} U_\lambda$ (which induces an open covering of the final sheaf of $\text{Cris}(X/S)$) and the complex $\mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S}^\bullet$, see Proposition 45.21.3. Now the result follows from a general result in cohomology on sites, namely that the alternating Čech complex computes the cohomology provided it gives the correct answer on all the pieces (insert future reference here).

Remark 45.24.5 (Quasi-coherence). In the situation of Remark 45.24.1 assume that $S \rightarrow S'$ is quasi-compact and quasi-separated and that $X \rightarrow S_0$ is quasi-compact and quasi-separated. Then for a crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules \mathcal{F} the sheaves $R^i f_{\text{cris},*} \mathcal{F}$ are locally quasi-coherent.

Hints: We have to show that the restrictions to T' are quasi-coherent $\mathcal{O}_{T'}$ -modules, where (U', T', δ') is any object of $\text{Cris}(X'/S')$. It suffices to do this when T' is affine. We use the formula (45.24.1.1), the fact that $T \rightarrow T'$ is quasi-compact and quasi-separated (as T is affine over the base change of T' by $S \rightarrow S'$), and Cohomology of Schemes, Lemma 29.4.4 to see that it suffices to show that the sheaves $R^i \tau_{U/T,*} \mathcal{F}_U$ are quasi-coherent. Note that $U \rightarrow T_0$ is also quasi-compact and quasi-separated, see Schemes, Lemmas 25.21.15 and 25.21.15.

This reduces us to proving that $R^i \tau_{X/S,*} \mathcal{F}$ is quasi-coherent on S in the case that p locally nilpotent on S . Here $\tau_{X/S}$ is the structure morphism, see Remark 45.9.6. We may work locally on S , hence we may assume S affine (see Lemma 45.9.5). Induction on the number of affines covering X and Mayer-Vietoris (Remark 45.24.2) reduces the question to the case where X is also affine (as in the proof of Cohomology of Schemes, Lemma 29.4.4). Say $X = \text{Spec}(C)$ and $S = \text{Spec}(A)$ so that (A, I, γ) and $A \rightarrow C$ are as in Situation 45.5.1. Choose a polynomial algebra P over A and a surjection $P \rightarrow C$ as in Section 45.17. Let (M, ∇) be the module corresponding to \mathcal{F} , see Proposition 45.17.4. Applying Proposition 45.21.3 we see that $R\Gamma(\text{Cris}(X/S), \mathcal{F})$ is represented by $M \otimes_D \Omega_D^*$. Note that completion isn't necessary as p is nilpotent in A ! We have to show that this is compatible with taking principal opens in $S = \text{Spec}(A)$. Suppose that $g \in A$. Then we conclude that similarly $R\Gamma(\text{Cris}(X_g/S_g), \mathcal{F})$ is computed by $M_g \otimes_{D_g} \Omega_{D_g}^*$ (again this uses that p -adic completion isn't necessary). Hence we conclude because localization is an exact functor on A -modules.

Remark 45.24.6 (Boundedness). In the situation of Remark 45.24.1 assume that $S \rightarrow S'$ is quasi-compact and quasi-separated and that $X \rightarrow S_0$ is of finite type and quasi-separated. Then there exists an integer i_0 such that for any crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules \mathcal{F} we have $R^i f_{\text{cris},*} \mathcal{F} = 0$ for all $i > i_0$.

Hints: Arguing as in Remark 45.24.5 (using Cohomology of Schemes, Lemma 29.4.4) we reduce to proving that $H^i(\text{Cris}(X/S), \mathcal{F}) = 0$ for $i \gg 0$ in the situation of Proposition 45.21.3 when C is a finite type algebra over A . This is clear as we can choose a finite polynomial algebra and we see that $\Omega_D^i = 0$ for $i \gg 0$.

Remark 45.24.7 (Specific boundedness). In Situation 45.7.5 let \mathcal{F} be a crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules. Assume that S_0 has a unique point and that $X \rightarrow S_0$ is of finite presentation.

- (1) If $\dim X = d$ and X/S_0 has embedding dimension e , then $H^i(\mathrm{Cris}(X/S), \mathcal{F}) = 0$ for $i > d + e$.
- (2) If X is separated and can be covered by q affines, and X/S_0 has embedding dimension e , then $H^i(\mathrm{Cris}(X/S), \mathcal{F}) = 0$ for $i > q + e$.

Hints: In case (1) we can use that

$$H^i(\mathrm{Cris}(X/S), \mathcal{F}) = H^i(X_{Zar}, Ru_{X/S,*}\mathcal{F})$$

and that $Ru_{X/S,*}\mathcal{F}$ is locally calculated by a de Rham complex constructed using an embedding of X into a smooth scheme of dimension e over S (see Lemma 45.21.4). These de Rham complexes are zero in all degrees $> e$. Hence (1) follows from Cohomology, Proposition 20.21.6. In case (2) we use the alternating Čech complex (see Remark 45.24.4) to reduce to the case X affine. In the affine case we prove the result using the de Rham complex associated to an embedding of X into a smooth scheme of dimension e over S (it takes some work to construct such a thing).

Remark 45.24.8 (Base change map). In the situation of Remark 45.24.1 assume $S = \mathrm{Spec}(A)$ and $S' = \mathrm{Spec}(A')$ are affine. Let \mathcal{F}' be an $\mathcal{O}_{X'/S'}$ -module. Let \mathcal{F} be the pullback of \mathcal{F}' . Then there is a canonical base change map

$$L(S' \rightarrow S)^* R\tau_{X'/S',*}\mathcal{F}' \longrightarrow R\tau_{X/S,*}\mathcal{F}$$

where $\tau_{X/S}$ and $\tau_{X'/S'}$ are the structure morphisms, see Remark 45.9.6. On global sections this gives a base change map

$$(45.24.8.1) \quad R\Gamma(\mathrm{Cris}(X'/S'), \mathcal{F}') \otimes_{A'}^L A \longrightarrow R\Gamma(\mathrm{Cris}(X/S), \mathcal{F})$$

in $D(A)$.

Hint: Compose the very general base change map of Cohomology on Sites, Remark 21.19.2 with the canonical map $Lf_{\mathrm{cris}}^*\mathcal{F}' \rightarrow f_{\mathrm{cris}}^*\mathcal{F}' = \mathcal{F}$.

Remark 45.24.9 (Base change isomorphism). The map (45.24.8.1) is an isomorphism provided all of the following conditions are satisfied:

- (1) p is nilpotent in A' ,
- (2) \mathcal{F}' is a crystal in quasi-coherent $\mathcal{O}_{X'/S'}$ -modules,
- (3) $X' \rightarrow S'_0$ is a quasi-compact, quasi-separated morphism,
- (4) $X = X' \times_{S'_0} S_0$,
- (5) \mathcal{F}' is a flat $\mathcal{O}_{X'/S'}$ -module,
- (6) $X' \rightarrow S'_0$ is a local complete intersection morphism (see More on Morphisms, Definition 36.42.2; this holds for example if $X' \rightarrow S'_0$ is syntomic or smooth),
- (7) X' and S_0 are Tor independent over S'_0 (see More on Algebra, Definition 15.47.1; this holds for example if either $S_0 \rightarrow S'_0$ or $X' \rightarrow S'_0$ is flat).

Hints: Condition (1) means that in the arguments below p -adic completion does nothing and can be ignored. Using condition (3) and Mayer Vietoris (see Remark 45.24.2) this reduces to the case where X' is affine. In fact by condition (6), after shrinking further, we can assume that $X' = \mathrm{Spec}(C')$ and we are given a presentation $C' = A'/I'[x_1, \dots, x_n]/(\bar{f}'_1, \dots, \bar{f}'_c)$ where $\bar{f}'_1, \dots, \bar{f}'_c$ is a Koszul-regular sequence in A'/I' . (This means that smooth locally $\bar{f}'_1, \dots, \bar{f}'_c$ forms a regular sequence, see More on Algebra, Lemma 15.21.17.) We choose a lift of \bar{f}'_i to an element $f'_i \in A'[x_1, \dots, x_n]$. By (4) we see that $X = \mathrm{Spec}(C)$ with $C = A/I[x_1, \dots, x_n]/(\bar{f}_1, \dots, \bar{f}_c)$ where $f_i \in A[x_1, \dots, x_n]$ is the image of f'_i . By

property (7) we see that $\bar{f}_1, \dots, \bar{f}_c$ is a Koszul-regular sequence in $A/I[x_1, \dots, x_n]$. The divided power envelope of $I'A[x_1, \dots, x_n] + (f'_1, \dots, f'_c)$ in $A[x_1, \dots, x_n]$ relative to γ' is

$$D' = A[x_1, \dots, x_n]\langle \xi_1, \dots, \xi_c \rangle / (\xi_i - f'_i)$$

see Lemma 45.2.4. Then you check that $\xi_1 - f'_1, \dots, \xi_n - f'_n$ is a Koszul-regular sequence in the ring $A[x_1, \dots, x_n]\langle \xi_1, \dots, \xi_c \rangle$. Similarly the divided power envelope of $IA[x_1, \dots, x_n] + (f_1, \dots, f_c)$ in $A[x_1, \dots, x_n]$ relative to γ is

$$D = A[x_1, \dots, x_n]\langle \xi_1, \dots, \xi_c \rangle / (\xi_i - f_i)$$

and $\xi_1 - f_1, \dots, \xi_n - f_n$ is a Koszul-regular sequence in the ring $A[x_1, \dots, x_n]\langle \xi_1, \dots, \xi_c \rangle$. It follows that $D' \otimes_{A'}^L A = D$. Condition (2) implies \mathcal{F}' corresponds to a pair (M', ∇) consisting of a D' -module with connection, see Proposition 45.17.4. Then $M = M' \otimes_{D'} D$ corresponds to the pullback \mathcal{F} . By assumption (5) we see that M' is a flat D' -module, hence

$$M = M' \otimes_{D'} D = M' \otimes_{D'} D' \otimes_{A'}^L A = M' \otimes_{A'}^L A$$

Since the modules of differentials $\Omega_{D'}$ and Ω_D (as defined in Section 45.17) are free D' -modules on the same generators we see that

$$M \otimes_D \Omega_D^\bullet = M' \otimes_{D'} \Omega_{D'}^\bullet \otimes_{D'} D = M' \otimes_{D'} \Omega_{D'}^\bullet \otimes_{A'}^L A$$

which proves what we want by Proposition 45.21.3.

Remark 45.24.10 (Rlim). Let p be a prime number. Let (A, I, γ) be a divided power ring with A an algebra over $\mathbf{Z}_{(p)}$ with p nilpotent in A/I . Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let X be a scheme over S_0 with p locally nilpotent on X . Let \mathcal{F} be any $\mathcal{O}_{X/S}$ -module. For $e \gg 0$ we have $(p^e) \subset I$ is preserved by γ , see Divided Power Algebra, Lemma 23.4.5. Set $S_e = \text{Spec}(A/p^e A)$ for $e \gg 0$. Then $\text{Cris}(X/S_e)$ is a full subcategory of $\text{Cris}(X/S)$ and we denote \mathcal{F}_e the restriction of \mathcal{F} to $\text{Cris}(X/S_e)$. Then

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) = R\lim_e R\Gamma(\text{Cris}(X/S_e), \mathcal{F}_e)$$

Hints: Suffices to prove this for \mathcal{F} injective. In this case the sheaves \mathcal{F}_e are injective modules too, the transition maps $\Gamma(\mathcal{F}_{e+1}) \rightarrow \Gamma(\mathcal{F}_e)$ are surjective, and we have $\Gamma(\mathcal{F}) = \lim_e \Gamma(\mathcal{F}_e)$ because any object of $\text{Cris}(X/S)$ is locally an object of one of the categories $\text{Cris}(X/S_e)$ by definition of $\text{Cris}(X/S)$.

Remark 45.24.11 (Comparison). Let p be a prime number. Let (A, I, γ) be a divided power ring with p nilpotent in A . Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let Y be a smooth scheme over S and set $X = Y \times_S S_0$. Let \mathcal{F} be a crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules. Then

- (1) γ extends to a divided power structure on the ideal of X in Y so that (X, Y, γ) is an object of $\text{Cris}(X/S)$,
- (2) the restriction \mathcal{F}_Y (see Section 45.10) comes endowed with a canonical integrable connection $\nabla : \mathcal{F}_Y \rightarrow \mathcal{F}_Y \otimes_{\mathcal{O}_Y} \Omega_{Y/S}$, and
- (3) we have

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) = R\Gamma(Y, \mathcal{F}_Y \otimes_{\mathcal{O}_Y} \Omega_{Y/S}^\bullet)$$

in $D(A)$.

Hints: See Divided Power Algebra, Lemma 23.4.2 for (1). See Lemma 45.15.1 for (2). For Part (3) note that there is a map, see (45.23.2.1). This map is an isomorphism when X is affine, see Lemma 45.21.4. This shows that $Ru_{X/S,*}\mathcal{F}$ and $\mathcal{F}_Y \otimes \Omega_{Y/S}^\bullet$ are quasi-isomorphic as complexes on $Y_{Zar} = X_{Zar}$. Since $R\Gamma(\text{Cris}(X/S), \mathcal{F}) = R\Gamma(X_{Zar}, Ru_{X/S,*}\mathcal{F})$ the result follows.

Remark 45.24.12 (Perfectness). Let p be a prime number. Let (A, I, γ) be a divided power ring with p nilpotent in A . Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let X be a proper smooth scheme over S_0 . Let \mathcal{F} be a crystal in finite locally free quasi-coherent $\mathcal{O}_{X/S}$ -modules. Then $R\Gamma(\text{Cris}(X/S), \mathcal{F})$ is a perfect object of $D(A)$.

Hints: By Remark 45.24.9 we have

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) \otimes_A^L A/I \cong R\Gamma(\text{Cris}(X/S_0), \mathcal{F}|_{\text{Cris}(X/S_0)})$$

By Remark 45.24.11 we have

$$R\Gamma(\text{Cris}(X/S_0), \mathcal{F}|_{\text{Cris}(X/S_0)}) = R\Gamma(X, \mathcal{F}_X \otimes \Omega_{X/S_0}^\bullet)$$

Using the stupid filtration on the de Rham complex we see that the last displayed complex is perfect in $D(A/I)$ as soon as the complexes

$$R\Gamma(X, \mathcal{F}_X \otimes \Omega_{X/S_0}^q)$$

are perfect complexes in $D(A/I)$, see More on Algebra, Lemma 15.56.4. This is true by standard arguments in coherent cohomology using that $\mathcal{F}_X \otimes \Omega_{X/S_0}^q$ is a finite locally free sheaf and $X \rightarrow S_0$ is proper and flat (insert future reference here). Applying More on Algebra, Lemma 15.57.4 we see that

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) \otimes_A^L A/I^n$$

is a perfect object of $D(A/I^n)$ for all n . This isn't quite enough unless A is Noetherian. Namely, even though I is locally nilpotent by our assumption that p is nilpotent, see Divided Power Algebra, Lemma 23.2.6, we cannot conclude that $I^n = 0$ for some n . A counter example is $\mathbf{F}_p\langle x \rangle$. To prove it in general when $\mathcal{F} = \mathcal{O}_{X/S}$ the argument of <http://math.columbia.edu/~dejong/wordpress/?p=2227> works. When the coefficients \mathcal{F} are non-trivial the argument of [Fal99] seems to be as follows. Reduce to the case $pA = 0$ by More on Algebra, Lemma 15.57.4. In this case the Frobenius map $A \rightarrow A$, $a \mapsto a^p$ factors as $A \rightarrow A/I \xrightarrow{\varphi} A$ (as $x^p = 0$ for $x \in I$). Set $X^{(1)} = X \otimes_{A/I, \varphi} A$. The absolute Frobenius morphism of X factors through a morphism $F_X : X \rightarrow X^{(1)}$ (a kind of relative Frobenius). Affine locally if $X = \text{Spec}(C)$ then $X^{(1)} = \text{Spec}(C \otimes_{A/I, \varphi} A)$ and F_X corresponds to $C \otimes_{A/I, \varphi} A \rightarrow C$, $c \otimes a \mapsto c^p a$. This defines morphisms of ringed topoi

$$(X/S)_{\text{cris}} \xrightarrow{(F_X)_{\text{cris}}} (X^{(1)}/S)_{\text{cris}} \xrightarrow{u_{X^{(1)}/S}} Sh(X_{Zar}^{(1)})$$

whose composition is denoted Frob_X . One then shows that $R\text{Frob}_{X,*}\mathcal{F}$ is representable by a perfect complex of $\mathcal{O}_{X^{(1)}}$ -modules(!) by a local calculation.

Remark 45.24.13 (Complete perfectness). Let p be a prime number. Let (A, I, γ) be a divided power ring with A a p -adically complete ring and p nilpotent in A/I . Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let X be a proper smooth scheme over S_0 . Let \mathcal{F} be a crystal in finite locally free quasi-coherent $\mathcal{O}_{X/S}$ -modules. Then $R\Gamma(\text{Cris}(X/S), \mathcal{F})$ is a perfect object of $D(A)$.

Hints: We know that $K = R\Gamma(\text{Cris}(X/S), \mathcal{F})$ is the derived limit $K = R\lim K_e$ of the cohomologies over $A/p^e A$, see Remark 45.24.10. Each K_e is a perfect complex of $D(A/p^e A)$ by Remark 45.24.12. Since A is p -adically complete the result follows from More on Algebra, Lemma 15.65.3.

Remark 45.24.14 (Complete comparison). Let p be a prime number. Let (A, I, γ) be a divided power ring with A a Noetherian p -adically complete ring and p nilpotent in A/I . Set $S = \text{Spec}(A)$ and $S_0 = \text{Spec}(A/I)$. Let Y be a proper smooth scheme over S and set $X = Y \times_S S_0$. Let \mathcal{F} be a finite type crystal in quasi-coherent $\mathcal{O}_{X/S}$ -modules. Then

- (1) there exists a coherent \mathcal{O}_Y -module \mathcal{F}_Y endowed with integrable connection

$$\nabla : \mathcal{F}_Y \longrightarrow \mathcal{F}_Y \otimes_{\mathcal{O}_Y} \Omega_{Y/S}$$

such that $\mathcal{F}_Y/p^e \mathcal{F}_Y$ is the module with connection over $A/p^e A$ found in Remark 45.24.11, and

- (2) we have

$$R\Gamma(\text{Cris}(X/S), \mathcal{F}) = R\Gamma(Y, \mathcal{F}_Y \otimes_{\mathcal{O}_Y} \Omega_{Y/S}^\bullet)$$

in $D(A)$.

Hints: The existence of \mathcal{F}_Y is Grothendieck’s existence theorem (insert future reference here). The isomorphism of cohomologies follows as both sides are computed as $R\lim$ of the versions modulo p^e (see Remark 45.24.10 for the left hand side; use the theorem on formal functions, see Cohomology of Schemes, Theorem 29.18.5 for the right hand side). Each of the versions modulo p^e are isomorphic by Remark 45.24.11.

45.25. Pulling back along purely inseparable maps

By an α_p -cover we mean a morphism of the form

$$X' = \text{Spec}(C[z]/(z^p - c)) \longrightarrow \text{Spec}(C) = X$$

where C is an \mathbf{F}_p -algebra and $c \in C$. Equivalently, X' is an α_p -torsor over X . An *iterated α_p -cover*⁷ is a morphism of schemes in characteristic p which is locally on the target a composition of finitely many α_p -covers. In this section we prove that pullback along such a morphism induces a quasi-isomorphism on crystalline cohomology after inverting the prime p . In fact, we prove a precise version of this result. We begin with a preliminary lemma whose formulation needs some notation.

Assume we have a ring map $B \rightarrow B'$ and quotients $\Omega_B \rightarrow \Omega$ and $\Omega_{B'} \rightarrow \Omega'$ satisfying the assumptions of Remark 45.6.11. Thus (45.6.11.1) provides a canonical map of complexes

$$c_M^\bullet : M \otimes_B \Omega^\bullet \longrightarrow M \otimes_B (\Omega')^\bullet$$

for all B -modules M endowed with integrable connection $\nabla : M \rightarrow M \otimes_B \Omega_B$.

Suppose we have $a \in B$, $z \in B'$, and a map $\theta : B' \rightarrow B'$ satisfying the following assumptions

- (1) $d(a) = 0$,

⁷This is nonstandard notation.

- (2) $\Omega' = B' \otimes_B \Omega \oplus B' dz$; we write $d(f) = d_1(f) + \partial_z(f) dz$ with $d_1(f) \in B' \otimes \Omega$ and $\partial_z(f) \in N'$ for all $f \in B'$,
- (3) $\theta : B' \rightarrow B'$ is B -linear,
- (4) $\partial_z \circ \theta = a$,
- (5) $B \rightarrow B'$ is universally injective (and hence $\Omega \rightarrow \Omega'$ is injective),
- (6) $af - \theta(\partial_z(f)) \in B$ for all $f \in B'$,
- (7) $(\theta \otimes 1)(d_1(f)) - d_1(\theta(f)) \in \Omega$ for all $f \in B'$ where $\theta \otimes 1 : B' \otimes \Omega \rightarrow B' \otimes \Omega$

These conditions are not logically independent. For example, assumption (4) implies that $\partial_z(af - \theta(\partial_z(f))) = 0$. Hence if the image of $B \rightarrow B'$ is the collection of elements annihilated by ∂_z , then (6) follows. A similar argument can be made for condition (7).

Lemma 45.25.1. *In the situation above there exists a map of complexes*

$$e_M^\bullet : M \otimes_B (\Omega')^\bullet \longrightarrow M \otimes_B \Omega^\bullet$$

such that $c_M^\bullet \circ e_M^\bullet$ and $e_M^\bullet \circ c_M^\bullet$ are homotopic to multiplication by a .

Proof. In this proof all tensor products are over B . Assumption (2) implies that

$$M \otimes (\Omega')^i = (B' \otimes M \otimes \Omega^i) \oplus (B' dz \otimes M \otimes \Omega^{i-1})$$

for all $i \geq 0$. A collection of additive generators for $M \otimes (\Omega')^i$ is formed by elements of the form $f\omega$ and elements of the form $f dz \wedge \eta$ where $f \in B'$, $\omega \in M \otimes \Omega^i$, and $\eta \in M \otimes \Omega^{i-1}$.

For $f \in B'$ we write

$$\epsilon(f) = af - \theta(\partial_z(f)) \quad \text{and} \quad \epsilon'(f) = (\theta \otimes 1)(d_1(f)) - d_1(\theta(f))$$

so that $\epsilon(f) \in B$ and $\epsilon'(f) \in \Omega$ by assumptions (6) and (7). We define e_M^\bullet by the rules $e_M^i(f\omega) = \epsilon(f)\omega$ and $e_M^i(f dz \wedge \eta) = \epsilon'(f) \wedge \eta$. We will see below that the collection of maps e_M^i is a map of complexes.

We define

$$h^i : M \otimes_B (\Omega')^i \longrightarrow M \otimes_B (\Omega')^{i-1}$$

by the rules $h^i(f\omega) = 0$ and $h^i(f dz \wedge \eta) = \theta(f)\eta$ for elements as above. We claim that

$$d \circ h + h \circ d = a - c_M^\bullet \circ e_M^\bullet$$

Note that multiplication by a is a map of complexes by (1). Hence, since c_M^\bullet is an injective map of complexes by assumption (5), we conclude that e_M^\bullet is a map of complexes. To prove the claim we compute

$$\begin{aligned} (d \circ h + h \circ d)(f\omega) &= h(d(f) \wedge \omega + f \nabla(\omega)) \\ &= \theta(\partial_z(f))\omega \\ &= af\omega - \epsilon(f)\omega \\ &= af\omega - c_M^i(e_M^i(f\omega)) \end{aligned}$$

The second equality because dz does not occur in $\nabla(\omega)$ and the third equality by assumption (6). Similarly, we have

$$\begin{aligned} (d \circ h + h \circ d)(fdz \wedge \eta) &= d(\theta(f)\eta) + h(d(f) \wedge dz \wedge \eta - fdz \wedge \nabla(\eta)) \\ &= d(\theta(f)) \wedge \eta + \theta(f)\nabla(\eta) - (\theta \otimes 1)(d_1(f)) \wedge \eta - \theta(f)\nabla(\eta) \\ &= d_1(\theta(f)) \wedge \eta + \partial_z(\theta(f))dz \wedge \eta - (\theta \otimes 1)(d_1(f)) \wedge \eta \\ &= afdz \wedge \eta - \epsilon'(f) \wedge \eta \\ &= afdz \wedge \eta - c_M^i(e_M^i(fdz \wedge \eta)) \end{aligned}$$

The second equality because $d(f) \wedge dz \wedge \eta = -dz \wedge d_1(f) \wedge \eta$. The fourth equality by assumption (4). On the other hand it is immediate from the definitions that $e_M^i(c_M^i(\omega)) = \epsilon(1)\omega = a\omega$. This proves the lemma. \square

Example 45.25.2. A standard example of the situation above occurs when $B' = B\langle z \rangle$ is the divided power polynomial ring over a divided power ring (B, J, δ) with divided powers δ' on $J' = B'_+ + JB' \subset B'$. Namely, we take $\Omega = \Omega_{B, \delta}$ and $\Omega' = \Omega_{B', \delta'}$. In this case we can take $a = 1$ and

$$\theta(\sum b_m z^{[m]}) = \sum b_m z^{[m+1]}$$

Note that

$$f - \theta(\partial_z(f)) = f(0)$$

equals the constant term. It follows that in this case Lemma 45.25.1 recovers the crystalline Poincaré lemma (Lemma 45.20.2).

Lemma 45.25.3. *In Situation 45.5.1. Assume D and Ω_D are as in (45.17.0.1) and (45.17.0.2). Let $\lambda \in D$. Let D' be the p -adic completion of*

$$D[z]\langle \xi \rangle / (\xi - (z^p - \lambda))$$

and let $\Omega_{D'}$ be the p -adic completion of the module of divided power differentials of D' over A . For any pair (M, ∇) over D satisfying (1), (2), (3), and (4) the canonical map of complexes (45.6.11.1)

$$c_M^\bullet : M \otimes_D^\wedge \Omega_D^\bullet \longrightarrow M \otimes_D^\wedge \Omega_{D'}^\bullet$$

has the following property: There exists a map e_M^\bullet in the opposite direction such that both $c_M^\bullet \circ e_M^\bullet$ and $e_M^\bullet \circ c_M^\bullet$ are homotopic to multiplication by p .

Proof. We will prove this using Lemma 45.25.1 with $a = p$. Thus we have to find $\theta : D' \rightarrow D'$ and prove (1), (2), (3), (4), (5), (6), (7). We first collect some information about the rings D and D' and the modules Ω_D and $\Omega_{D'}$.

Writing

$$D[z]\langle \xi \rangle / (\xi - (z^p - \lambda)) = D\langle \xi \rangle[z] / (z^p - \xi - \lambda)$$

we see that D' is the p -adic completion of the free D -module

$$\bigoplus_{i=0, \dots, p-1} \bigoplus_{n \geq 0} z^i \xi^{[n]} D$$

where $\xi^{[0]} = 1$. It follows that $D \rightarrow D'$ has a continuous D -linear section, in particular $D \rightarrow D'$ is universally injective, i.e., (5) holds. We think of D' as a divided power algebra over A with divided power ideal $\bar{J}' = \bar{J}D' + (\xi)$. Then D' is

also the p -adic completion of the divided power envelope of the ideal generated by $z^p - \lambda$ in D , see Lemma 45.2.4. Hence

$$\Omega_{D'} = \Omega_D \otimes_D^\wedge D' \oplus D' dz$$

by Lemma 45.6.6. This proves (2). Note that (1) is obvious.

At this point we construct θ . (We wrote a PARI/gp script theta.gp verifying some of the formulas in this proof which can be found in the scripts subdirectory of the stacks project.) Before we do so we compute the derivative of the elements $z^i \xi^{[n]}$. We have $dz^i = iz^{i-1} dz$. For $n \geq 1$ we have

$$d\xi^{[n]} = \xi^{[n-1]} d\xi = -\xi^{[n-1]} d\lambda + pz^{p-1} \xi^{[n-1]} dz$$

because $\xi = z^p - \lambda$. For $0 < i < p$ and $n \geq 1$ we have

$$\begin{aligned} d(z^i \xi^{[n]}) &= iz^{i-1} \xi^{[n]} dz + z^i \xi^{[n-1]} d\xi \\ &= iz^{i-1} \xi^{[n]} dz + z^i \xi^{[n-1]} d(z^p - \lambda) \\ &= -z^i \xi^{[n-1]} d\lambda + (iz^{i-1} \xi^{[n]} + pz^{i+p-1} \xi^{[n-1]}) dz \\ &= -z^i \xi^{[n-1]} d\lambda + (iz^{i-1} \xi^{[n]} + pz^{i-1} (\xi + \lambda) \xi^{[n-1]}) dz \\ &= -z^i \xi^{[n-1]} d\lambda + ((i + pn) z^{i-1} \xi^{[n]} + p\lambda z^{i-1} \xi^{[n-1]}) dz \end{aligned}$$

the last equality because $\xi \xi^{[n-1]} = n \xi^{[n]}$. Thus we see that

$$\begin{aligned} \partial_z(z^i) &= iz^{i-1} \\ \partial_z(\xi^{[n]}) &= pz^{p-1} \xi^{[n-1]} \\ \partial_z(z^i \xi^{[n]}) &= (i + pn) z^{i-1} \xi^{[n]} + p\lambda z^{i-1} \xi^{[n-1]} \end{aligned}$$

Motivated by these formulas we define θ by the rules

$$\begin{aligned} \theta(z^j) &= p \frac{z^{j+1}}{j+1} & j = 0, \dots, p-1, \\ \theta(z^{p-1} \xi^{[m]}) &= \xi^{[m+1]} & m \geq 1, \\ \theta(z^j \xi^{[m]}) &= \frac{pz^{j+1} \xi^{[m]} - \theta(p\lambda z^j \xi^{[m-1]})}{(j+1+pm)} & 0 \leq j < p-1, m \geq 1 \end{aligned}$$

where in the last line we use induction on m to define our choice of θ . Working this out we get (for $0 \leq j < p-1$ and $1 \leq m$)

$$\theta(z^j \xi^{[m]}) = \frac{pz^{j+1} \xi^{[m]}}{(j+1+pm)} - \frac{p^2 \lambda z^{j+1} \xi^{[m-1]}}{(j+1+pm)(j+1+p(m-1))} + \dots + \frac{(-1)^m p^{m+1} \lambda^m z^{j+1}}{(j+1+pm) \dots (j+1)}$$

although we will not use this expression below. It is clear that θ extends uniquely to a p -adically continuous D -linear map on D' . By construction we have (3) and (4). It remains to prove (6) and (7).

Proof of (6) and (7). As θ is D -linear and continuous it suffices to prove that $p - \theta \circ \partial_z$, resp. $(\theta \otimes 1) \circ d_1 - d_1 \circ \theta$ gives an element of D , resp. Ω_D when evaluated on the elements $z^i \xi^{[n]}$ ⁸. Set $D_0 = \mathbf{Z}_{(p)}[\lambda]$ and $D'_0 = \mathbf{Z}_{(p)}[z, \lambda] \langle \xi \rangle / (\xi - z^p + \lambda)$. Observe that each of the expressions above is an element of D'_0 or $\Omega_{D'_0}$. Hence it suffices to prove the result in the case of $D_0 \rightarrow D'_0$. Note that D_0 and D'_0 are torsion free rings and that $D_0 \otimes \mathbf{Q} = \mathbf{Q}[\lambda]$ and $D'_0 \otimes \mathbf{Q} = \mathbf{Q}[z, \lambda]$. Hence $D_0 \subset D'_0$ is the

⁸This can be done by direct computation: It turns out that $p - \theta \circ \partial_z$ evaluated on $z^i \xi^{[n]}$ gives zero except for 1 which is mapped to p and ξ which is mapped to $-p\lambda$. It turns out that $(\theta \otimes 1) \circ d_1 - d_1 \circ \theta$ evaluated on $z^i \xi^{[n]}$ gives zero except for $z^{p-1} \xi$ which is mapped to $-\lambda$.

subring of elements annihilated by ∂_z and (6) follows from (4), see the discussion directly preceding Lemma 45.25.1. Similarly, we have $d_1(f) = \partial_\lambda(f)d\lambda$ hence

$$((\theta \otimes 1) \circ d_1 - d_1 \circ \theta)(f) = (\theta(\partial_\lambda(f)) - \partial_\lambda(\theta(f)))d\lambda$$

Applying ∂_z to the coefficient we obtain

$$\begin{aligned} \partial_z(\theta(\partial_\lambda(f)) - \partial_\lambda(\theta(f))) &= p\partial_\lambda(f) - \partial_z(\partial_\lambda(\theta(f))) \\ &= p\partial_\lambda(f) - \partial_\lambda(\partial_z(\theta(f))) \\ &= p\partial_\lambda(f) - \partial_\lambda(pf) = 0 \end{aligned}$$

whence the coefficient does not depend on z as desired. This finishes the proof of the lemma. \square

Note that an iterated α_p -cover $X' \rightarrow X$ (as defined in the introduction to this section) is finite locally free. Hence if X is connected the degree of $X' \rightarrow X$ is constant and is a power of p .

Lemma 45.25.4. *Let p be a prime number. Let (S, \mathcal{I}, γ) be a divided power scheme over $\mathbf{Z}_{(p)}$ with $p \in \mathcal{I}$. We set $S_0 = V(\mathcal{I}) \subset S$. Let $f : X' \rightarrow X$ be an iterated α_p -cover of schemes over S_0 with constant degree q . Let \mathcal{F} be any crystal in quasi-coherent sheaves on X and set $\mathcal{F}' = f_{cris}^* \mathcal{F}$. In the distinguished triangle*

$$Ru_{X/S,*} \mathcal{F} \longrightarrow f_* Ru_{X'/S,*} \mathcal{F}' \longrightarrow E \longrightarrow Ru_{X/S,*} \mathcal{F}[1]$$

the object E has cohomology sheaves annihilated by q .

Proof. Note that $X' \rightarrow X$ is a homeomorphism hence we can identify the underlying topological spaces of X and X' . The question is clearly local on X , hence we may assume X, X' , and S affine and $X' \rightarrow X$ given as a composition

$$X' = X_n \rightarrow X_{n-1} \rightarrow X_{n-2} \rightarrow \dots \rightarrow X_0 = X$$

where each morphism $X_{i+1} \rightarrow X_i$ is an α_p -cover. Denote \mathcal{F}_i the pullback of \mathcal{F} to X_i . It suffices to prove that each of the maps

$$R\Gamma(\text{Cris}(X_i/S), \mathcal{F}_i) \longrightarrow R\Gamma(\text{Cris}(X_{i+1}/S), \mathcal{F}_{i+1})$$

fits into a triangle whose third member has cohomology groups annihilated by p . (This uses axiom TR4 for the triangulated category $D(X)$. Details omitted.)

Hence we may assume that $S = \text{Spec}(A)$, $X = \text{Spec}(C)$, $X' = \text{Spec}(C')$ and $C' = C[z]/(z^p - c)$ for some $c \in C$. Choose a polynomial algebra P over A and a surjection $P \rightarrow C$. Let D be the p -adically completed divided power envelope of $\text{Ker}(P \rightarrow C)$ in P as in (45.17.0.1). Set $P' = P[z]$ with surjection $P' \rightarrow C'$ mapping z to the class of z in C' . Choose a lift $\lambda \in D$ of $c \in C$. Then we see that the p -adically completed divided power envelope D' of $\text{Ker}(P' \rightarrow C')$ in P' is isomorphic to the p -adic completion of $D[z][\xi]/(\xi - (z^p - \lambda))$, see Lemma 45.25.3 and its proof. Thus we see that the result follows from this lemma by the computation of cohomology of crystals in quasi-coherent modules in Proposition 45.21.3. \square

The bound in the following lemma is probably not optimal.

Lemma 45.25.5. *With notations and assumptions as in Lemma 45.25.4 the map*

$$f^* : H^i(\text{Cris}(X/S), \mathcal{F}) \longrightarrow H^i(\text{Cris}(X'/S), \mathcal{F}')$$

has kernel and cokernel annihilated by q^{i+1} .

Proof. This follows from the fact that E has nonzero cohomology sheaves in degrees -1 and up, so that the spectral sequence $H^a(\mathcal{H}^b(E)) \Rightarrow H^{a+b}(E)$ converges. This combined with the long exact cohomology sequence associated to a distinguished triangle gives the bound. \square

In Situation 45.7.5 assume that $p \in \mathcal{I}$. Set

$$X^{(1)} = X \times_{S_0, F_{S_0}} S_0.$$

Denote $F_{X/S_0} : X \rightarrow X^{(1)}$ the relative Frobenius morphism.

Lemma 45.25.6. *In the situation above, assume that $X \rightarrow S_0$ is smooth of relative dimension d . Then F_{X/S_0} is an iterated α_p -cover of degree p^d . Hence Lemmas 45.25.4 and 45.25.5 apply to this situation. In particular, for any crystal in quasi-coherent modules \mathcal{G} on $\text{Cris}(X^{(1)}/S)$ the map*

$$F_{X/S_0}^* : H^i(\text{Cris}(X^{(1)}/S), \mathcal{G}) \longrightarrow H^i(\text{Cris}(X/S), F_{X/S_0, \text{cris}}^* \mathcal{G})$$

has kernel and cokernel annihilated by $p^{d(i+1)}$.

Proof. It suffices to prove the first statement. To see this we may assume that X is étale over $\mathbf{A}_{S_0}^d$, see Morphisms, Lemma 28.37.20. Denote $\varphi : X \rightarrow \mathbf{A}_{S_0}^d$ this étale morphism. In this case the relative Frobenius of X/S_0 fits into a diagram

$$\begin{array}{ccc} X & \longrightarrow & X^{(1)} \\ \downarrow & & \downarrow \\ \mathbf{A}_{S_0}^d & \longrightarrow & \mathbf{A}_{S_0}^d \end{array}$$

where the lower horizontal arrow is the relative Frobenius morphism of $\mathbf{A}_{S_0}^d$ over S_0 . This is the morphism which raises all the coordinates to the p th power, hence it is an iterated α_p -cover. The proof is finished by observing that the diagram is a fibre square, see the proof of Étale Cohomology, Theorem 44.80.4. \square

45.26. Frobenius action on crystalline cohomology

In this section we prove that Frobenius pullback induces a quasi-isomorphism on crystalline cohomology after inverting the prime p . But in order to even formulate this we need to work in a special situation.

Situation 45.26.1. In Situation 45.7.5 assume the following

- (1) $S = \text{Spec}(A)$ for some divided power ring (A, I, γ) with $p \in I$,
- (2) there is given a homomorphism of divided power rings $\sigma : A \rightarrow A$ such that $\sigma(x) = x^p \bmod pA$ for all $x \in A$.

In Situation 45.26.1 the morphism $\text{Spec}(\sigma) : S \rightarrow S$ is a lift of the absolute Frobenius $F_{S_0} : S_0 \rightarrow S_0$ and since the diagram

$$\begin{array}{ccc} X & \xrightarrow{F_X} & X \\ \downarrow & & \downarrow \\ S_0 & \xrightarrow{F_{S_0}} & S_0 \end{array}$$

is commutative where $F_X : X \rightarrow X$ is the absolute Frobenius morphism of X . Thus we obtain a morphism of crystalline topoi

$$(F_X)_{\text{cris}} : (X/S)_{\text{cris}} \longrightarrow (X/S)_{\text{cris}}$$

see Remark 45.9.3. Here is the terminology concerning F -crystals following the notation of Saavedra, see [SR72].

Definition 45.26.2. In Situation 45.26.1 an F -crystal on X/S (relative to σ) is a pair $(\mathcal{E}, F_{\mathcal{E}})$ given by a crystal in finite locally free $\mathcal{O}_{X/S}$ -modules \mathcal{E} together with a map

$$F_{\mathcal{E}} : (F_X)_{\text{cris}}^* \mathcal{E} \longrightarrow \mathcal{E}$$

An F -crystal is called *nondegenerate* if there exists an integer $i \geq 0$ a map $V : \mathcal{E} \rightarrow (F_X)_{\text{cris}}^* \mathcal{E}$ such that $V \circ F_{\mathcal{E}} = p^i \text{id}$.

Remark 45.26.3. Let (\mathcal{E}, F) be an F -crystal as in Definition 45.26.2. In the literature the nondegeneracy condition is often part of the definition of an F -crystal. Moreover, often it is also assumed that $F \circ V = p^n \text{id}$. What is needed for the result below is that there exists an integer $j \geq 0$ such that $\text{Ker}(F)$ and $\text{Coker}(F)$ are killed by p^j . If the rank of \mathcal{E} is bounded (for example if X is quasi-compact), then both of these conditions follow from the nondegeneracy condition as formulated in the definition. Namely, suppose R is a ring, $r \geq 1$ is an integer and $K, L \in \text{Mat}(r \times r, R)$ are matrices with $KL = p^i 1_{r \times r}$. Then $\det(K) \det(L) = p^{ri}$. Let L' be the adjugate matrix of L , i.e., $L'L = LL' = \det(L)$. Set $K' = p^{ri} K$ and $j = ri + i$. Then we have $K'L = p^j 1_{r \times r}$ as $KL = p^i$ and

$$LK' = LK \det(L) \det(M) = LKLL' \det(M) = Lp^i L' \det(M) = p^j 1_{r \times r}$$

It follows that if V is as in Definition 45.26.2 then setting $V' = p^N V$ where $N > i \cdot \text{rank}(\mathcal{E})$ we get $V' \circ F = p^{N+i}$ and $F \circ V' = p^{N+i}$.

Theorem 45.26.4. In Situation 45.26.1 let $(\mathcal{E}, F_{\mathcal{E}})$ be a nondegenerate F -crystal. Assume A is a p -adically complete Noetherian ring and that $X \rightarrow S_0$ is proper smooth. Then the canonical map

$$F_{\mathcal{E}} \circ (F_X)_{\text{cris}}^* : R\Gamma(\text{Cris}(X/S), \mathcal{E}) \otimes_{A, \sigma}^{\mathbf{L}} A \longrightarrow R\Gamma(\text{Cris}(X/S), \mathcal{E})$$

becomes an isomorphism after inverting p .

Proof. We first write the arrow as a composition of three arrows. Namely, set

$$X^{(1)} = X \times_{S_0, F_{S_0}} S_0$$

and denote $F_{X/S_0} : X \rightarrow X^{(1)}$ the relative Frobenius morphism. Denote $\mathcal{E}^{(1)}$ the base change of \mathcal{E} by $\text{Spec}(\sigma)$, in other words the pullback of \mathcal{E} to $\text{Cris}(X^{(1)}/S)$ by the morphism of crystalline topoi associated to the commutative diagram

$$\begin{array}{ccc} X^{(1)} & \longrightarrow & X \\ \downarrow & & \downarrow \\ S & \xrightarrow{\text{Spec}(\sigma)} & S \end{array}$$

Then we have the base change map

$$(45.26.4.1) \quad R\Gamma(\text{Cris}(X/S), \mathcal{E}) \otimes_{A, \sigma}^{\mathbf{L}} A \longrightarrow R\Gamma(\text{Cris}(X^{(1)}/S), \mathcal{E}^{(1)})$$

see Remark 45.24.8. Note that the composition of $F_{X/S_0} : X \rightarrow X^{(1)}$ with the projection $X^{(1)} \rightarrow X$ is the absolute Frobenius morphism F_X . Hence we see that $F_{X/S_0}^* \mathcal{E}^{(1)} = (F_X)_{\text{cris}}^* \mathcal{E}$. Thus pullback by F_{X/S_0} is a map

$$(45.26.4.2) \quad F_{X/S_0}^* : R\Gamma(\text{Cris}(X^{(1)}/S), \mathcal{E}^{(1)}) \longrightarrow R\Gamma(\text{Cris}(X/S), (F_X)_{\text{cris}}^* \mathcal{E})$$

Finally we can use $F_{\mathcal{E}}$ to get a map

$$(45.26.4.3) \quad R\Gamma(\text{Cris}(X/S), (F_X)_{\text{cris}}^* \mathcal{E}) \longrightarrow R\Gamma(\text{Cris}(X/S), \mathcal{E})$$

The map of the theorem is the composition of the three maps (45.26.4.1), (45.26.4.2), and (45.26.4.3) above. The first is a quasi-isomorphism modulo all powers of p by Remark 45.24.9. Hence it is a quasi-isomorphism since the complexes involved are perfect in $D(A)$ see Remark 45.24.13. The third map is a quasi-isomorphism after inverting p simply because $F_{\mathcal{E}}$ has an inverse up to a power of p , see Remark 45.26.3. Finally, the second is an isomorphism after inverting p by Lemma 45.25.6. \square

Pro-étale Cohomology

46.1. Introduction

The material in this chapter and more can be found in the preprint [BS13].

The goal of this chapter is to introduce the pro-étale topology and show how it simplifies the introduction of ℓ -adic cohomology in algebraic geometry.

A brief overview of the history of this material as we have understood it. In [Gro77, Exposés V and VI] Grothendieck et al developed a theory for dealing with ℓ -adic sheaves as inverse systems of sheaves of $\mathbf{Z}/\ell^n\mathbf{Z}$ -modules. In his second paper on the Weil conjectures ([Del74a]) Deligne introduced a derived category of ℓ -adic sheaves as a certain 2-limit of categories of complexes of sheaves of $\mathbf{Z}/\ell^n\mathbf{Z}$ -modules on the étale site of a scheme X . This approach is used in the paper by Beilinson, Bernstein, and Deligne ([BBD82]) as the basis for their beautiful theory of perverse sheaves. In a paper entitled “Continuous Étale Cohomology” ([Jan88]) Uwe Jannsen discusses an important variant of the cohomology of a ℓ -adic sheaf on a variety over a field. His paper is followed up by a paper of Torsten Ekedahl ([Eke90]) who discusses the adic formalism needed to work comfortably with derived categories defined as limits.

The goal of this chapter is to show that, if we work with the pro-étale site of a scheme, then one can avoid some of the technicalities these authors encountered. This comes at the expense of having to work with non-Noetherian schemes, even when one is only interested in working with ℓ -adic sheaves and cohomology of such on varieties over an algebraically closed field.

46.2. Some topology

Some preliminaries. We have defined *spectral spaces* and *spectral maps* of spectral spaces in Topology, Section 5.22. The spectrum of a ring is a spectral space, see Algebra, Lemma 10.25.2.

Lemma 46.2.1. *Let X be a spectral space. Let $X_0 \subset X$ be the set of closed points. The following are equivalent*

- (1) *Every open covering of X can be refined by a finite disjoint union decomposition $X = \coprod U_i$ with U_i open and closed in X .*
- (2) *The composition $X_0 \rightarrow X \rightarrow \pi_0(X)$ is bijective.*

Moreover, if X_0 is closed in X and every point of X specializes to a unique point of X_0 , then these conditions are satisfied.

Proof. We will use without further mention that X_0 is quasi-compact (Topology, Lemma 5.11.9) and $\pi_0(X)$ is profinite (Topology, Lemma 5.22.8). Picture

$$\begin{array}{ccc} X_0 & \longrightarrow & X \\ & \searrow f & \downarrow \pi \\ & & \pi_0(X) \end{array}$$

If (2) holds, the continuous bijective map $f : X_0 \rightarrow \pi_0(X)$ is a homeomorphism by Topology, Lemma 5.16.8. Given an open covering $X = \bigcup U_i$, we get an open covering $\pi_0(X) = \bigcup f(X_0 \cap U_i)$. By Topology, Lemma 5.21.3 we can find a finite open covering of the form $\pi_0(X) = \coprod V_j$ which refines this covering. Since $X_0 \rightarrow \pi_0(X)$ is bijective each connected component of X has a unique closed point, whence is equal to the set of points specializing to this closed point. Hence $\pi^{-1}(V_j)$ is the set of points specializing to the points of $f^{-1}(V_j)$. Now, if $f^{-1}(V_j) \subset X_0 \cap U_i \subset U_i$, then it follows that $\pi^{-1}(V_j) \subset U_i$ (because the open set U_i is closed under generalizations). In this way we see that the open covering $X = \coprod \pi^{-1}(V_j)$ refines the covering we started out with. In this way we see that (2) implies (1).

Assume (1). Let $x, y \in X$ be closed points. Then we have the open covering $X = (X \setminus \{x\}) \cup (X \setminus \{y\})$. It follows from (1) that there exists a disjoint union decomposition $X = U \amalg V$ with U and V open (and closed) and $x \in U$ and $y \in V$. In particular we see that every connected component of X has at most one closed point. By Topology, Lemma 5.11.8 every connected component (being closed) also does have a closed point. Thus $X_0 \rightarrow \pi_0(X)$ is bijective. In this way we see that (1) implies (2).

Assume X_0 is closed in X and every point specializes to a unique point of X_0 . Then X_0 is a spectral space (Topology, Lemma 5.22.4) consisting of closed points, hence profinite (Topology, Lemma 5.22.7). Let $x, y \in X_0$ be distinct. By Topology, Lemma 5.21.3 we can find a disjoint union decomposition $X_0 = U_0 \amalg V_0$ with U_0 and V_0 open and closed. Let $\{U_i\}$ be the set of quasi-compact open subsets of X such that $U_0 = X_0 \cap U_i$. Similarly, let $\{V_j\}$ be the set of quasi-compact open subsets of X such that $V_0 = X_0 \cap V_j$. If $U_i \cap V_j$ is nonempty for all i, j , then there exists a point ξ contained in all of them (use the $U_i \cap V_j$ is constructible, hence closed in the constructible topology, and use Topology, Lemmas 5.22.2 and 5.11.6). However, since X is sober and V_0 is closed in X , the intersection $\bigcap U_i$ is the set of points specializing to U_0 . Similarly, $\bigcap V_j$ is the set of points specializing to V_0 . Since $U_0 \cap V_0$ is empty this is a contradiction. Thus we find disjoint quasi-compact opens $U, V \subset X$ such that $U_0 = X_0 \cap U$ and $V_0 = X_0 \cap V$. Observe that $X = U \cup V = U \amalg V$ as $X_0 \subset U \cup V$ (use Topology, Lemma 5.11.8). This proves that x, y are not in the same connected component of X . In other words, $X_0 \rightarrow \pi_0(X)$ is injective. The map is also surjective by Topology, Lemma 5.11.8 and the fact that connected components are closed. In this way we see that the final condition implies (1). \square

Example 46.2.2. Let T be a profinite space. Let $t \in T$ be a point and assume that $T \setminus \{t\}$ is not quasi-compact. Let $X = T \times \{0, 1\}$. Consider the topology on X with a subbase given by the sets $U \times \{0, 1\}$ for $U \subset T$ open, $X \setminus \{(t, 0)\}$, and $U \times \{1\}$ for $U \subset T$ open with $t \notin U$. The set of closed points of X is $X_0 = T \times \{0\}$ and $(t, 1)$ is in the closure of X_0 . Moreover, $X_0 \rightarrow \pi_0(X)$ is a bijection. This example

shows that conditions (1) and (2) of Lemma 46.2.1 do not imply the set of closed points is closed.

It turns out it is more convenient to work with spectral spaces which have the slightly stronger property mentioned in the final statement of Lemma 46.2.1. We give this property a name.

Definition 46.2.3. A spectral space X is *w-local* if the set of closed points X_0 is closed and every point of X specializes to a unique closed point. A continuous map $f : X \rightarrow Y$ of w -local spaces is *w-local* if it is spectral and maps any closed point of X to a closed point of Y .

We have seen in the proof of Lemma 46.2.1 that in this case $X_0 \rightarrow \pi_0(X)$ is a homeomorphism and that $X_0 \cong \pi_0(X)$ is a profinite space. Moreover, a connected component of X is exactly the set of points specializing to a given $x \in X_0$.

Lemma 46.2.4. *Let X be a w -local spectral space. If $Y \subset X$ is closed, then Y is w -local.*

Proof. The subset $Y_0 \subset Y$ of closed points is closed because $Y_0 = X_0 \cap Y$. Since X is w -local, every $y \in Y$ specializes to a unique point of X_0 . This specialization is in Y , and hence also in Y_0 , because $\overline{\{y\}} \subset Y$. In conclusion, Y is w -local. \square

Lemma 46.2.5. *Let X be a spectral space. Let*

$$\begin{array}{ccc} Y & \longrightarrow & T \\ \downarrow & & \downarrow \\ X & \longrightarrow & \pi_0(X) \end{array}$$

be a cartesian diagram in the category of topological spaces with T profinite. Then Y is spectral and $T = \pi_0(Y)$. If moreover X is w -local, then Y is w -local, $Y \rightarrow X$ is w -local, and the set of closed points of Y is the inverse image of the set of closed points of X .

Proof. Note that Y is a closed subspace of $X \times T$ as $\pi_0(X)$ is a profinite space hence Hausdorff (use Topology, Lemmas 5.22.8 and 5.3.4). Since $X \times T$ is spectral (Topology, Lemma 5.22.9) it follows that Y is spectral (Topology, Lemma 5.22.4). Let $Y \rightarrow \pi_0(Y) \rightarrow T$ be the canonical factorization (Topology, Lemma 5.6.8). It is clear that $\pi_0(Y) \rightarrow T$ is surjective. The fibres of $Y \rightarrow T$ are homeomorphic to the fibres of $X \rightarrow \pi_0(X)$. Hence these fibres are connected. It follows that $\pi_0(Y) \rightarrow T$ is injective. We conclude that $\pi_0(Y) \rightarrow T$ is a homeomorphism by Topology, Lemma 5.16.8.

Next, assume that X is w -local and let $X_0 \subset X$ be the set of closed points. The inverse image $Y_0 \subset Y$ of X_0 in Y maps bijectively onto T as $X_0 \rightarrow \pi_0(X)$ is a bijection by Lemma 46.2.1. Moreover, Y_0 is quasi-compact as a closed subset of the spectral space Y . Hence $Y_0 \rightarrow \pi_0(Y) = T$ is a homeomorphism by Topology, Lemma 5.16.8. It follows that all points of Y_0 are closed in Y . Conversely, if $y \in Y$ is a closed point, then it is closed in the fibre of $Y \rightarrow \pi_0(Y) = T$ and hence its image x in X is closed in the (homeomorphic) fibre of $X \rightarrow \pi_0(X)$. This implies $x \in X_0$ and hence $y \in Y_0$. Thus Y_0 is the collection of closed points of Y and for each $y \in Y_0$ the set of generalizations of y is the fibre of $Y \rightarrow \pi_0(Y)$. The lemma follows. \square

46.3. Local isomorphisms

We start with a definition.

Definition 46.3.1. Let $\varphi : A \rightarrow B$ be a ring map.

- (1) We say $A \rightarrow B$ is a *local isomorphism* if for every prime $\mathfrak{q} \subset B$ there exists a $g \in B$, $g \notin \mathfrak{q}$ such that $A \rightarrow B_g$ induces an open immersion $\text{Spec}(B_g) \rightarrow \text{Spec}(A)$.
- (2) We say $A \rightarrow B$ *identifies local rings* if for every prime $\mathfrak{q} \subset B$ the canonical map $A_{\varphi^{-1}(\mathfrak{q})} \rightarrow B_{\mathfrak{q}}$ is an isomorphism.

We list some elementary properties.

Lemma 46.3.2. Let $A \rightarrow B$ and $A \rightarrow A'$ be ring maps. Let $B' = B \otimes_A A'$ be the base change of B .

- (1) If $A \rightarrow B$ is a local isomorphism, then $A' \rightarrow B'$ is a local isomorphism.
- (2) If $A \rightarrow B$ identifies local rings, then $A' \rightarrow B'$ identifies local rings.

Proof. Omitted. □

Lemma 46.3.3. Let $A \rightarrow B$ and $B \rightarrow C$ be ring maps.

- (1) If $A \rightarrow B$ and $B \rightarrow C$ are local isomorphisms, then $A \rightarrow C$ is a local isomorphism.
- (2) If $A \rightarrow B$ and $B \rightarrow C$ identify local rings, then $A \rightarrow C$ identifies local rings.

Proof. Omitted. □

Lemma 46.3.4. Let A be a ring. Let $B \rightarrow C$ be an A -algebra homomorphism.

- (1) If $A \rightarrow B$ and $A \rightarrow C$ are local isomorphisms, then $B \rightarrow C$ is a local isomorphism.
- (2) If $A \rightarrow B$ and $A \rightarrow C$ identify local rings, then $B \rightarrow C$ identifies local rings.

Proof. Omitted. □

Lemma 46.3.5. Let $A \rightarrow B$ be a local isomorphism. Then

- (1) $A \rightarrow B$ is étale,
- (2) $A \rightarrow B$ identifies local rings,
- (3) $A \rightarrow B$ is quasi-finite.

Proof. Omitted. □

Lemma 46.3.6. Let $A \rightarrow B$ be a local isomorphism. Then there exist $n \geq 0$, $g_1, \dots, g_n \in B$, $f_1, \dots, f_n \in A$ such that $(g_1, \dots, g_n) = B$ and $A_{f_i} \cong B_{g_i}$.

Proof. Omitted. □

Lemma 46.3.7. Let $p : (Y, \mathcal{O}_Y) \rightarrow (X, \mathcal{O}_X)$ and $q : (Z, \mathcal{O}_Z) \rightarrow (X, \mathcal{O}_X)$ be morphisms of locally ringed spaces. If $\mathcal{O}_Y = p^{-1}\mathcal{O}_X$, then

$$\text{Mor}_{\text{LRS}/(X, \mathcal{O}_X)}((Z, \mathcal{O}_Z), (Y, \mathcal{O}_Y)) \longrightarrow \text{Mor}_{\text{Top}/X}(Z, Y), \quad (f, f^\sharp) \longmapsto f$$

is bijective. Here $\text{LRS}/(X, \mathcal{O}_X)$ is the category of locally ringed spaces over X and Top/X is the category of topological spaces over X .

Proof. This is immediate from the definitions. □

Lemma 46.3.8. *Let A be a ring. Set $X = \operatorname{Spec}(A)$. The functor*

$$B \longmapsto \operatorname{Spec}(B)$$

from the category of A -algebras B such that $A \rightarrow B$ identifies local rings to the category of topological spaces over X is fully faithful.

Proof. This follows from Lemma 46.3.7 and the fact that if $A \rightarrow B$ identifies local rings, then the pullback of the structure sheaf of $\operatorname{Spec}(A)$ via $p : \operatorname{Spec}(B) \rightarrow \operatorname{Spec}(A)$ is equal to the structure sheaf of $\operatorname{Spec}(B)$. \square

46.4. Ind-Zariski algebra

We start with a definition; please see Remark 46.6.9 for a comparison with the corresponding definition of the article [BS13].

Definition 46.4.1. A ring map $A \rightarrow B$ is said to be *ind-Zariski* if B can be written as a filtered colimit $B = \operatorname{colim} B_i$ with each $A \rightarrow B_i$ a local isomorphism.

An example of an Ind-Zariski map is a localization $A \rightarrow S^{-1}A$, see Algebra, Lemma 10.9.9. The category of ind-Zariski algebras is closed under several natural operations.

Lemma 46.4.2. *Let $A \rightarrow B$ and $A \rightarrow A'$ be ring maps. Let $B' = B \otimes_A A'$ be the base change of B . If $A \rightarrow B$ is ind-Zariski, then $A' \rightarrow B'$ is ind-Zariski.*

Proof. Omitted. \square

Lemma 46.4.3. *Let $A \rightarrow B$ and $B \rightarrow C$ be ring maps. If $A \rightarrow B$ and $B \rightarrow C$ are ind-Zariski, then $A \rightarrow C$ is ind-Zariski.*

Proof. Omitted. \square

Lemma 46.4.4. *Let A be a ring. Let $B \rightarrow C$ be an A -algebra homomorphism. If $A \rightarrow B$ and $A \rightarrow C$ are ind-Zariski, then $B \rightarrow C$ is ind-Zariski.*

Proof. Omitted. \square

Lemma 46.4.5. *A filtered colimit of ind-Zariski A -algebras is ind-Zariski over A .*

Proof. Omitted. \square

Lemma 46.4.6. *Let $A \rightarrow B$ be ind-Zariski. Then $A \rightarrow B$ identifies local rings,*

Proof. Omitted. \square

46.5. Constructing w-local affine schemes

An affine scheme X is called *w-local* if its underlying topological space is w-local (Definition 46.2.3). It turns out given any ring A there is a canonical faithfully flat ind-Zariski ring map $A \rightarrow A_w$ such that $\operatorname{Spec}(A_w)$ is w-local. The key to constructing A_w is the following simple lemma.

Lemma 46.5.1. *Let A be a ring. Set $X = \operatorname{Spec}(A)$. Let $Z \subset X$ be a locally closed subscheme which of the form $D(f) \cap V(I)$ for some $f \in A$ and ideal $I \subset A$. Then*

- (1) *there exists a multiplicative subset $S \subset A$ such that $\operatorname{Spec}(S^{-1}A)$ maps by a homeomorphism to the set of points of X specializing to Z ,*
- (2) *the A -algebra $A_{\tilde{Z}} = S^{-1}A$ depends only on the underlying locally closed subset $Z \subset X$,*

(3) Z is a closed subscheme of $\text{Spec}(A_{\tilde{Z}})$,

If $A \rightarrow A'$ is a ring map and $Z' \subset X' = \text{Spec}(A')$ is a locally closed subscheme of the same form which maps into Z , then there is a unique A -algebra map $A_{\tilde{Z}} \rightarrow (A')_{\tilde{Z}'}$.

Proof. Let $S \subset A$ be the multiplicative set of elements which map to invertible elements of $\Gamma(Z, \mathcal{O}_Z) = (A/I)_f$. If \mathfrak{p} is a prime of A which does not specialize to Z , then \mathfrak{p} generates the unit ideal in $(A/I)_f$. Hence we can write $f^n = g + h$ for some $n \geq 0$, $g \in \mathfrak{p}$, $h \in I$. Then $g \in S$ and we see that \mathfrak{p} is not in the spectrum of $S^{-1}A$. Conversely, if \mathfrak{p} does specialize to Z , say $\mathfrak{p} \subset \mathfrak{q} \supset I$ with $f \notin \mathfrak{q}$, then we see that $S^{-1}A$ maps to $A_{\mathfrak{q}}$ and hence \mathfrak{p} is in the spectrum of $S^{-1}A$. This proves (1).

The isomorphism class of the localization $S^{-1}A$ depends only on the corresponding subset $\text{Spec}(S^{-1}A) \subset \text{Spec}(A)$, whence (2) holds. By construction $S^{-1}A$ maps surjectively onto $(A/I)_f$, hence (3). The final statement follows as the multiplicative subset $S' \subset A'$ corresponding to Z' contains the image of the multiplicative subset S . \square

Let A be a ring. Let $E \subset A$ be a finite subset. We get a stratification of $X = \text{Spec}(A)$ into locally closed subschemes by looking at the vanishing behaviour of the elements of E . More precisely, given a disjoint union decomposition $E = E' \amalg E''$ we set

(46.5.1.1)

$$Z(E', E'') = \bigcap_{f \in E'} D(f) \cap \bigcap_{f \in E''} V(f) = D\left(\prod_{f \in E'} f\right) \cap V\left(\sum_{f \in E''} fA\right)$$

The points of $Z(E', E'')$ are exactly those $x \in X$ such that $f \in E'$ maps to a nonzero element in $\kappa(x)$ and $f \in E''$ maps to zero in $\kappa(x)$. Thus it is clear that

$$(46.5.1.2) \quad X = \coprod_{E=E' \amalg E''} Z(E', E'')$$

set theoretically. Observe that each stratum is constructible.

Lemma 46.5.2. *Let $X = \text{Spec}(A)$ as above. Given any finite stratification $X = \coprod T_i$ by constructible subsets, there exists a finite subset $E \subset A$ such that the stratification (46.5.1.2) refines $X = \coprod T_i$.*

Proof. We may write $T_i = \bigcup_j U_{i,j} \cap V_{i,j}^c$ as a finite union for some $U_{i,j}$ and $V_{i,j}$ quasi-compact open in X . Then we may write $U_{i,j} = \bigcup D(f_{i,j,k})$ and $V_{i,j} = \bigcup D(g_{i,j,l})$. Then we set $E = \{f_{i,j,k}\} \cup \{g_{i,j,l}\}$. This does the job, because the stratification (46.5.1.2) is the one whose strata are labeled by the vanishing pattern of the elements of E which clearly refines the given stratification. \square

We continue the discussion. Given a finite subset $E \subset A$ we set

$$(46.5.2.1) \quad A_E = \prod_{E=E' \amalg E''} A_{\tilde{Z}(E', E'')}$$

with notation as in Lemma 46.5.1. This makes sense because (46.5.1.1) shows that each $Z(E', E'')$ has the correct shape. We take the spectrum of this ring and denote it

$$(46.5.2.2) \quad X_E = \text{Spec}(A_E) = \coprod_{E=E' \amalg E''} X_{E', E''}$$

with $X_{E', E''} = \text{Spec}(A_{\tilde{Z}(E', E'')})$. Note that

$$(46.5.2.3) \quad Z_E = \coprod_{E=E' \amalg E''} Z(E', E'') \longrightarrow X_E$$

is a closed subscheme. By construction the closed subscheme Z_E contains all the closed points of the affine scheme X_E as every point of $X_{E',E''}$ specializes to a point of $Z(E', E'')$.

Let $I(A)$ be the partially ordered set of all finite subsets of A . This is a directed partially ordered set. For $E_1 \subset E_2$ there is a canonical transition map $A_{E_1} \rightarrow A_{E_2}$ of A -algebras. Namely, given a decomposition $E_2 = E'_2 \amalg E''_2$ we set $E'_1 = E_1 \cap E'_2$ and $E''_1 = E_1 \cap E''_2$. Then observe that $Z(E'_1, E''_1) \subset Z(E'_2, E''_2)$ hence a unique A -algebra map $A_{\widetilde{Z}(E'_1, E''_1)} \rightarrow A_{\widetilde{Z}(E'_2, E''_2)}$ by Lemma 46.5.1. Using these maps collectively we obtain the desired ring map $A_{E_1} \rightarrow A_{E_2}$. Observe that the corresponding map of affine schemes

$$(46.5.2.4) \quad X_{E_2} \longrightarrow X_{E_1}$$

maps Z_{E_2} into Z_{E_1} . By uniqueness we obtain a system of A -algebras over $I(A)$ and we set

$$(46.5.2.5) \quad A_w = \operatorname{colim}_{E \in I(A)} A_E$$

This A -algebra is ind-Zariski and faithfully flat over A . Finally, we set $X_w = \operatorname{Spec}(A_w)$ and endow it with the closed subscheme $Z = \lim_{E \in I(A)} Z_E$. In a formula

$$(46.5.2.6) \quad X_w = \lim_{E \in I(A)} X_E \supset Z = \lim_{E \in I(A)} Z_E$$

Lemma 46.5.3. *Let $X = \operatorname{Spec}(A)$ be an affine scheme. With $A \rightarrow A_w$, $X_w = \operatorname{Spec}(A_w)$, and $Z \subset X_w$ as above.*

- (1) $A \rightarrow A_w$ is ind-Zariski and faithfully flat,
- (2) $X_w \rightarrow X$ induces a bijection $Z \rightarrow X$,
- (3) Z is the set of closed points of X_w ,
- (4) Z is a reduced scheme, and
- (5) every point of X_w specializes to a unique point of Z .

In particular, X_w is w -local (Definition 46.2.3).

Proof. The map $A \rightarrow A_w$ is ind-Zariski by construction. For every E the morphism $Z_E \rightarrow X$ is a bijection, hence (2). As $Z \subset X_w$ we conclude $X_w \rightarrow X$ is surjective and $A \rightarrow A_w$ is faithfully flat by Algebra, Lemma 10.38.15. This proves (1).

Suppose that $y \in X_w$, $y \notin Z$. Then there exists an E such that the image of y in X_E is not contained in Z_E . Then for all $E \subset E'$ also y maps to an element of $X_{E'}$ not contained in $Z_{E'}$. Let $T_{E'} \subset X_{E'}$ be the reduced closed subscheme which is the closure of the image of y . It is clear that $T = \lim_{E \subset E'} T_{E'}$ is the closure of y in X_w . For every $E \subset E'$ the scheme $T_{E'} \cap Z_{E'}$ is nonempty by construction of $X_{E'}$. Hence $\lim T_{E'} \cap Z_{E'}$ is nonempty and we conclude that $T \cap Z$ is nonempty. Thus y is not a closed point. It follows that every closed point of X_w is in Z .

Suppose that $y \in X_w$ specializes to $z, z' \in Z$. We will show that $z = z'$ which will finish the proof of (3) and will imply (5). Let $x, x' \in X$ be the images of z and z' . Since $Z \rightarrow X$ is bijective it suffices to show that $x = x'$. If $x \neq x'$, then there exists an $f \in A$ such that $x \in D(f)$ and $x' \in V(f)$ (or vice versa). Set $E = \{f\}$ so that

$$X_E = \operatorname{Spec}(A_f) \amalg \operatorname{Spec}(A_{V(f)})$$

Then we see that z and z' map x_E and x'_E which are in different parts of the given decomposition of X_E above. But then it is impossible for x_E and x'_E to be specializations of a common point. This is the desired contradiction.

Recall that given a finite subset $E \subset A$ we have Z_E is a disjoint union of the locally closed subschemes $Z(E', E'')$ each isomorphic to the spectrum of $(A/I)_f$ where I is the ideal generated by E'' and f the product of the elements of E' . Any nilpotent element b of $(A/I)_f$ is the class of g/f^n for some $g \in A$. Then setting $E' = E \cup \{g\}$ the reader verifies that b pulls back to zero under the transition map $Z_{E'} \rightarrow Z_E$ of the system. This proves (4). \square

Remark 46.5.4. Let A be a ring. Let κ be an infinite cardinal bigger or equal than the cardinality of A . Then the cardinality of A_w (Lemma 46.5.3) is at most κ . Namely, each A_E has cardinality at most κ and the set of finite subsets of A has cardinality at most κ as well. Thus the result follows as $\kappa \otimes \kappa = \kappa$, see Sets, Section 3.6.

Lemma 46.5.5 (Universal property of the construction). *Let A be a ring. Let $A \rightarrow A_w$ be the ring map constructed in Lemma 46.5.3. For any ring map $A \rightarrow B$ such that $\text{Spec}(B)$ is w -local, there is a unique factorization $A \rightarrow A_w \rightarrow B$ such that $\text{Spec}(B) \rightarrow \text{Spec}(A_w)$ is w -local.*

Proof. Denote $Y = \text{Spec}(B)$ and $Y_0 \subset Y$ the set of closed points. Denote $f : Y \rightarrow X$ the given morphism. Recall that Y_0 is profinite, in particular every constructible subset of Y_0 is open and closed. Let $E \subset A$ be a finite subset. Recall that $A_w = \text{colim } A_E$ and that the set of closed points of $\text{Spec}(A_w)$ is the limit of the closed subsets $Z_E \subset X_E = \text{Spec}(A_E)$. Thus it suffices to show there is a unique factorization $A \rightarrow A_E \rightarrow B$ such that $Y \rightarrow X_E$ maps Y_0 into Z_E . Since $Z_E \rightarrow X = \text{Spec}(A)$ is bijective, and since the strata $Z(E', E'')$ are constructible we see that

$$Y_0 = \coprod f^{-1}(Z(E', E'')) \cap Y_0$$

is a disjoint union decomposition into open and closed subsets. As $Y_0 = \pi_0(Y)$ we obtain a corresponding decomposition of Y into open and closed pieces. Thus it suffices to construct the factorization in case $f(Y_0) \subset Z(E', E'')$ for some decomposition $E = E' \amalg E''$. In this case $f(Y)$ is contained in the set of points of X specializing to $Z(E', E'')$ which is homeomorphic to $X_{E', E''}$. Thus we obtain a unique continuous map $Y \rightarrow X_{E', E''}$ over X . By Lemma 46.3.7 this corresponds to a unique morphism of schemes $Y \rightarrow X_{E', E''}$ over X . This finishes the proof. \square

Recall that the spectrum of a ring is profinite if and only if every point is closed. There are in fact a whole slew of equivalent conditions that imply this. See Algebra, Lemma 10.25.5 or Topology, Lemma 5.22.7.

Lemma 46.5.6. *Let A be a ring such that $\text{Spec}(A)$ is profinite. Let $A \rightarrow B$ be a ring map. Then $\text{Spec}(B)$ is profinite in each of the following cases:*

- (1) if $\mathfrak{q}, \mathfrak{q}' \subset B$ lie over the same prime of A , then neither $\mathfrak{q} \subset \mathfrak{q}'$, nor $\mathfrak{q}' \subset \mathfrak{q}$,
- (2) $A \rightarrow B$ induces algebraic extensions of residue fields,
- (3) $A \rightarrow B$ is a local isomorphism,
- (4) $A \rightarrow B$ identifies local rings,
- (5) $A \rightarrow B$ is weakly étale,
- (6) $A \rightarrow B$ is quasi-finite,
- (7) $A \rightarrow B$ is unramified,
- (8) $A \rightarrow B$ is étale,
- (9) B is a filtered colimit of A -algebras as in (1) – (8),
- (10) etc.

Proof. By the references mentioned above (Algebra, Lemma 10.25.5 or Topology, Lemma 5.22.7) there are no specializations between distinct points of $\text{Spec}(A)$ and $\text{Spec}(B)$ is profinite if and only if there are no specializations between distinct points of $\text{Spec}(B)$. These specializations can only happen in the fibres of $\text{Spec}(B) \rightarrow \text{Spec}(A)$. In this way we see that (1) is true.

The assumption in (2) implies all primes of B are maximal by Algebra, Lemma 10.34.9. Thus (2) holds. If $A \rightarrow B$ is a local isomorphism or identifies local rings, then the residue field extensions are trivial, so (3) and (4) follow from (2). If $A \rightarrow B$ is weakly étale, then More on Algebra, Lemma 15.67.16 tells us it induces separable algebraic residue field extensions, so (5) follows from (2). If $A \rightarrow B$ is quasi-finite, then the fibres are finite discrete topological spaces. Hence (6) follows from (1). Hence (3) follows from (1). Cases (7) and (8) follow from this as unramified and étale ring map are quasi-finite (Algebra, Lemmas 10.144.6 and 10.138.6). If $B = \text{colim } B_i$ is a filtered colimit of A -algebras, then $\text{Spec}(B) = \text{colim } \text{Spec}(B_i)$, hence if each $\text{Spec}(B_i)$ is profinite, so is $\text{Spec}(B)$. This proves (9). \square

Lemma 46.5.7. *Let A be a ring. Let $V(I) \subset \text{Spec}(A)$ be a closed subset which is a profinite topological space. Then there exists an ind-Zariski ring map $A \rightarrow B$ such that $\text{Spec}(B)$ is w -local, the set of closed points is $V(IB)$, and $A/I \cong B/IB$.*

Proof. Let $A \rightarrow A_w$ and $Z \subset Y = \text{Spec}(A_w)$ as in Lemma 46.5.3. Let $T \subset Z$ be the inverse image of $V(I)$. Then $T \rightarrow V(I)$ is a homeomorphism by Topology, Lemma 5.16.8. Let $B = (A_w)_{\tilde{T}}$, see Lemma 46.5.1. It is clear that B is w -local with closed points $V(IB)$. The ring map $A/I \rightarrow B/IB$ is ind-Zariski and induces a homeomorphism on underlying topological spaces. Hence it is an isomorphism by Lemma 46.3.8. \square

Lemma 46.5.8. *Let A be a ring such that $X = \text{Spec}(A)$ is w -local. Let $I \subset A$ be the radical ideal cutting out the set X_0 of closed points in X . Let $A \rightarrow B$ be a ring map inducing algebraic extensions on residue fields at primes. Then*

- (1) every point of $Z = V(IB)$ is a closed point of $\text{Spec}(B)$,
- (2) there exists an ind-Zariski ring map $B \rightarrow C$ such that
 - (a) $B/IB \rightarrow C/IC$ is an isomorphism,
 - (b) the space $Y = \text{Spec}(C)$ is w -local,
 - (c) the induced map $p: Y \rightarrow X$ is w -local, and
 - (d) $p^{-1}(X_0)$ is the set of closed points of Y .

Proof. By Lemma 46.5.6 applied to $A/I \rightarrow B/IB$ all points of $Z = V(IB) = \text{Spec}(B/IB)$ are closed, in fact $\text{Spec}(B/IB)$ is a profinite space. To finish the proof we apply Lemma 46.5.7 to $IB \subset B$. \square

46.6. Identifying local rings versus ind-Zariski

An ind-Zariski ring map $A \rightarrow B$ identifies local rings (Lemma 46.4.6). The converse does not hold (Examples, Section 82.37). However, it turns out that there is a kind of structure theorem for ring maps which identify local rings in terms of ind-Zariski ring maps, see Proposition 46.6.6.

Let A be a ring. Let $X = \text{Spec}(A)$. The space of connected components $\pi_0(X)$ is a profinite space by Topology, Lemma 5.22.8 (and Algebra, Lemma 10.25.2).

Lemma 46.6.1. *Let A be a ring. Let $X = \text{Spec}(A)$. Let $T \subset \pi_0(X)$ be a closed subset. There exists a surjective ind-Zariski ring map $A \rightarrow B$ such that $\text{Spec}(B) \rightarrow \text{Spec}(A)$ induces a homeomorphism of $\text{Spec}(B)$ with the inverse image of T in X .*

Proof. Let $Z \subset X$ be the inverse image of T . Then Z is the intersection $Z = \bigcap Z_\alpha$ of the open and closed subsets of X containing Z , see Topology, Lemma 5.11.12. For each α we have $Z_\alpha = \text{Spec}(A_\alpha)$ where $A \rightarrow A_\alpha$ is a local isomorphism (a localization at an idempotent). Setting $B = \text{colim } A_\alpha$ proves the lemma. \square

Lemma 46.6.2. *Let A be a ring and let $X = \text{Spec}(A)$. Let T be a profinite space and let $T \rightarrow \pi_0(X)$ be a continuous map. There exists an ind-Zariski ring map $A \rightarrow B$ such that with $Y = \text{Spec}(B)$ the diagram*

$$\begin{array}{ccc} Y & \longrightarrow & \pi_0(Y) \\ \downarrow & & \downarrow \\ X & \longrightarrow & \pi_0(X) \end{array}$$

is cartesian in the category of topological spaces and such that $\pi_0(Y) = T$ as spaces over $\pi_0(X)$.

Proof. Namely, write $T = \lim T_i$ as the limit of an inverse system finite discrete spaces over a directed partially ordered set (see Topology, Lemma 5.21.2). For each i let $Z_i = \text{Im}(T \rightarrow \pi_0(X) \times T_i)$. This is a closed subset. Observe that $X \times T_i$ is the spectrum of $A_i = \prod_{t \in T_i} A$ and that $A \rightarrow A_i$ is a local isomorphism. By Lemma 46.6.1 we see that $Z_i \subset \pi_0(X \times T_i) = \pi_0(X) \times T_i$ corresponds to a surjection $A_i \rightarrow B_i$ which is ind-Zariski such that $\text{Spec}(B_i) = X \times_{\pi_0(X)} Z_i$ as subsets of $X \times T_i$. The transition maps $T_i \rightarrow T_{i'}$ induce maps $Z_i \rightarrow Z_{i'}$ and $X \times_{\pi_0(X)} Z_i \rightarrow X \times_{\pi_0(X)} Z_{i'}$. Hence ring maps $B_{i'} \rightarrow B_i$ (Lemmas 46.3.8 and 46.4.6). Set $B = \text{colim } B_i$. Because $T = \lim Z_i$ we have $X \times_{\pi_0(X)} T = \lim X \times_{\pi_0(X)} Z_i$ and hence $Y = \text{Spec}(B) = \lim \text{Spec}(B_i)$ fits into the cartesian diagram

$$\begin{array}{ccc} Y & \longrightarrow & T \\ \downarrow & & \downarrow \\ X & \longrightarrow & \pi_0(X) \end{array}$$

of topological spaces. By Lemma 46.2.5 we conclude that $T = \pi_0(Y)$. \square

Example 46.6.3. Let k be a field. Let T be a profinite topological space. There exists an ind-Zariski ring map $k \rightarrow A$ such that $\text{Spec}(A)$ is homeomorphic to T . Namely, just apply Lemma 46.6.2 to $T \rightarrow \pi_0(\text{Spec}(k)) = \{*\}$. In fact, in this case we have

$$A = \text{colim } \text{Map}(T_i, k)$$

whenever we write $T = \lim T_i$ as a filtered limit with each T_i finite.

Lemma 46.6.4. *Let $A \rightarrow B$ be ring map such that*

- (1) $A \rightarrow B$ identifies local rings,
- (2) the topological spaces $\text{Spec}(B)$, $\text{Spec}(A)$ are w -local,
- (3) $\text{Spec}(B) \rightarrow \text{Spec}(A)$ is w -local, and
- (4) $\pi_0(\text{Spec}(B)) \rightarrow \pi_0(\text{Spec}(A))$ is bijective.

Then $A \rightarrow B$ is an isomorphism

Proof. Let $X_0 \subset X = \text{Spec}(A)$ and $Y_0 \subset Y = \text{Spec}(B)$ be the sets of closed points. By assumption Y_0 maps into X_0 and the induced map $Y_0 \rightarrow X_0$ is a bijection. As a space $\text{Spec}(A)$ is the disjoint union of the spectra of the local rings of A at closed points. Similarly for B . Hence $X \rightarrow Y$ is a bijection. Since $A \rightarrow B$ is flat we have going down (Algebra, Lemma 10.38.17). Thus Algebra, Lemma 10.40.11 shows for any prime $\mathfrak{q} \subset B$ lying over $\mathfrak{p} \subset A$ we have $B_{\mathfrak{q}} = B_{\mathfrak{p}}$. Since $B_{\mathfrak{q}} = A_{\mathfrak{p}}$ by assumption, we see that $A_{\mathfrak{p}} = B_{\mathfrak{p}}$ for all primes \mathfrak{p} of A . Thus $A = B$ by Algebra, Lemma 10.23.1. \square

Lemma 46.6.5. *Let $A \rightarrow B$ be ring map such that*

- (1) *$A \rightarrow B$ identifies local rings,*
- (2) *the topological spaces $\text{Spec}(B)$, $\text{Spec}(A)$ are w -local, and*
- (3) *$\text{Spec}(B) \rightarrow \text{Spec}(A)$ is w -local.*

Then $A \rightarrow B$ is ind-Zariski.

Proof. Set $X = \text{Spec}(A)$ and $Y = \text{Spec}(B)$. Let $X_0 \subset X$ and $Y_0 \subset Y$ be the set of closed points. Let $A \rightarrow A'$ be the ind-Zariski morphism of affine schemes such that with $X' = \text{Spec}(A')$ the diagram

$$\begin{array}{ccc} X' & \longrightarrow & \pi_0(X') \\ \downarrow & & \downarrow \\ X & \longrightarrow & \pi_0(X) \end{array}$$

is cartesian in the category of topological spaces and such that $\pi_0(X') = \pi_0(Y)$ as spaces over $\pi_0(X)$, see Lemma 46.6.2. By Lemma 46.2.5 we see that X' is w -local and the set of closed points $X'_0 \subset X'$ is the inverse image of X_0 .

We obtain a continuous map $Y \rightarrow X'$ of underlying topological spaces over X identifying $\pi_0(Y)$ with $\pi_0(X')$. By Lemma 46.3.8 (and Lemma 46.4.6) this corresponds to a morphism of affine schemes $Y \rightarrow X'$ over X . Since $Y \rightarrow X$ maps Y_0 into X_0 we see that $Y \rightarrow X'$ maps Y_0 into X'_0 , i.e., $Y \rightarrow X'$ is w -local. By Lemma 46.6.4 we see that $Y \cong X'$ and we win. \square

The following proposition is a warm up for the type of result we will prove later.

Proposition 46.6.6. *Let $A \rightarrow B$ be a ring map which identifies local rings. Then there exists a faithfully flat, ind-Zariski ring map $B \rightarrow B'$ such that $A \rightarrow B'$ is ind-Zariski.*

Proof. Let $A \rightarrow A_w$, resp. $B \rightarrow B_w$ be the faithfully flat, ind-Zariski ring map constructed in Lemma 46.5.3 for A , resp. B . Since $\text{Spec}(B_w)$ is w -local, there exists a unique factorization $A \rightarrow A_w \rightarrow B_w$ such that $\text{Spec}(B_w) \rightarrow \text{Spec}(A_w)$ is w -local by Lemma 46.5.5. Note that $A_w \rightarrow B_w$ identifies local rings, see Lemma 46.3.4. By Lemma 46.6.5 this means $A_w \rightarrow B_w$ is ind-Zariski. Since $B \rightarrow B_w$ is faithfully flat, ind-Zariski (Lemma 46.5.3) and the composition $A \rightarrow B \rightarrow B_w$ is ind-Zariski (Lemma 46.4.3) the proposition is proved. \square

The proposition above allows us to characterize the affine, weakly contractible objects in the pro-Zariski site of an affine scheme.

Lemma 46.6.7. *Let A be a ring. The following are equivalent*

- (1) *every faithfully flat ring map $A \rightarrow B$ identifying local rings has a section,*

- (2) every faithfully flat ind-Zariski ring map $A \rightarrow B$ has a section, and
 (3) A satisfies
 (a) $\text{Spec}(A)$ is w -local, and
 (b) $\pi_0(\text{Spec}(A))$ is extremally disconnected.

Proof. The equivalence of (1) and (2) follows immediately from Proposition 46.6.6.

Assume (3)(a) and (3)(b). Let $A \rightarrow B$ be faithfully flat and ind-Zariski. We will use without further mention the fact that a flat map $A \rightarrow B$ is faithfully flat if and only if every closed point of $\text{Spec}(A)$ is in the image of $\text{Spec}(B) \rightarrow \text{Spec}(A)$. We will show that $A \rightarrow B$ has a section.

Let $I \subset A$ be an ideal such that $V(I) \subset \text{Spec}(A)$ is the set of closed points of $\text{Spec}(A)$. We may replace B by the ring C constructed in Lemma 46.5.8 for $A \rightarrow B$ and $I \subset A$. Thus we may assume $\text{Spec}(B)$ is w -local such that the set of closed points of $\text{Spec}(B)$ is $V(IB)$.

Assume $\text{Spec}(B)$ is w -local and the set of closed points of $\text{Spec}(B)$ is $V(IB)$. Choose a continuous section to the surjective continuous map $V(IB) \rightarrow V(I)$. This is possible as $V(I) \cong \pi_0(\text{Spec}(A))$ is extremally disconnected, see Topology, Proposition 5.25.6. The image is a closed subspace $T \subset \pi_0(\text{Spec}(B)) \cong V(IB)$ mapping homeomorphically onto $\pi_0(A)$. Replacing B by the ind-Zariski quotient ring constructed in Lemma 46.6.1 we see that we may assume $\pi_0(\text{Spec}(B)) \rightarrow \pi_0(\text{Spec}(A))$ is bijective. At this point $A \rightarrow B$ is an isomorphism by Lemma 46.6.4.

Assume (1) or equivalently (2). Let $A \rightarrow A_w$ be the ring map constructed in Lemma 46.5.3. By (1) there is a section $A_w \rightarrow A$. Thus $\text{Spec}(A)$ is homeomorphic to a closed subset of $\text{Spec}(A_w)$. By Lemma 46.2.4 we see (3)(a) holds. Finally, let $T \rightarrow \pi_0(A)$ be a surjective map with T an extremally disconnected, quasi-compact, Hausdorff topological space (Topology, Lemma 5.25.9). Choose $A \rightarrow B$ as in Lemma 46.6.2 adapted to $T \rightarrow \pi_0(\text{Spec}(A))$. By (1) there is a section $B \rightarrow A$. Thus we see that $T = \pi_0(\text{Spec}(B)) \rightarrow \pi_0(\text{Spec}(A))$ has a section. A formal categorical argument, using Topology, Proposition 5.25.6, implies that $\pi_0(\text{Spec}(A))$ is extremally disconnected. \square

Lemma 46.6.8. *Let A be a ring. There exists a faithfully flat, ind-Zariski ring map $A \rightarrow B$ such that B satisfies the equivalent conditions of Lemma 46.6.7.*

Proof. We first apply Lemma 46.5.3 to see that we may assume that $\text{Spec}(A)$ is w -local. Choose an extremally disconnected space T and a surjective continuous map $T \rightarrow \pi_0(\text{Spec}(A))$, see Topology, Lemma 5.25.9. Note that T is profinite. Apply Lemma 46.6.2 to find an ind-Zariski ring map $A \rightarrow B$ such that $\pi_0(\text{Spec}(B)) \rightarrow \pi_0(\text{Spec}(A))$ realizes $T \rightarrow \pi_0(\text{Spec}(A))$ and such that

$$\begin{array}{ccc} \text{Spec}(B) & \longrightarrow & \pi_0(\text{Spec}(B)) \\ \downarrow & & \downarrow \\ \text{Spec}(A) & \longrightarrow & \pi_0(\text{Spec}(A)) \end{array}$$

is cartesian in the category of topological spaces. Note that $\text{Spec}(B)$ is w -local, that $\text{Spec}(B) \rightarrow \text{Spec}(A)$ is w -local, and that the set of closed points of $\text{Spec}(B)$ is the inverse image of the set of closed points of $\text{Spec}(A)$, see Lemma 46.2.5. Thus condition (3) of Lemma 46.6.7 holds for B . \square

Remark 46.6.9. In each of Lemmas 46.6.1, 46.6.2, Proposition 46.6.6, and Lemma 46.6.8 we find an ind-Zariski ring map with some properties. In the paper [BS13] the authors use the notion of an ind-(Zariski localization) which is a filtered colimit of finite products of principal localizations. It is possible to replace ind-Zariski by ind-(Zariski localization) in each of the results listed above. However, we do not need this and the notion of an ind-Zariski homomorphism of rings as defined here has slightly better formal properties. Moreover, the notion of an ind-Zariski ring map is the natural analogue of the notion of an ind-étale ring map defined in the next section.

46.7. Ind-étale algebra

We start with a definition.

Definition 46.7.1. A ring map $A \rightarrow B$ is said to be *ind-étale* if B can be written as a filtered colimit of étale A -algebras.

The category of ind-étale algebras is closed under a number of natural operations.

Lemma 46.7.2. *Let $A \rightarrow B$ and $A \rightarrow A'$ be ring maps. Let $B' = B \otimes_A A'$ be the base change of B . If $A \rightarrow B$ is ind-étale, then $A' \rightarrow B'$ is ind-étale.*

Proof. Omitted. □

Lemma 46.7.3. *Let $A \rightarrow B$ and $B \rightarrow C$ be ring maps. If $A \rightarrow B$ and $B \rightarrow C$ are ind-étale, then $A \rightarrow C$ is ind-étale.*

Proof. Omitted. □

Lemma 46.7.4. *A filtered colimit of ind-étale A -algebras is ind-étale over A .*

Proof. Omitted. □

Lemma 46.7.5. *Let A be a ring. Let $B \rightarrow C$ be an A -algebra map of ind-étale A -algebras. Then C is an ind-étale B -algebra.*

Proof. Write $B = \operatorname{colim} B_i$ and $C = \operatorname{colim} C_j$ as filtered colimits of étale A -algebras. Then

$$C = B \otimes_B C = \operatorname{colim}_{(i,j)} B \otimes_{B_i} C_j$$

where the colimit is over the partially ordered set of pairs (i, j) such that $B_i \rightarrow B \rightarrow C$ factors through $C_j \rightarrow C$. Note that the factorization $B_i \rightarrow C_j$ is étale by Algebra, Lemma 10.138.9. Some details omitted. □

Lemma 46.7.6. *Let $A \rightarrow B$ be ind-étale. Then $A \rightarrow B$ is weakly étale (More on Algebra, Definition 15.67.1).*

Proof. This follows from More on Algebra, Lemma 15.67.13. □

Lemma 46.7.7. *Let A be a ring and let $I \subset A$ be an ideal. The base change functor*

$$\text{ind-étale } A\text{-algebras} \longrightarrow \text{ind-étale } A/I\text{-algebras}, \quad C \longmapsto C/IC$$

has a fully faithful right adjoint v . In particular, given an ind-étale A/I -algebra \overline{C} there exists an ind-étale A -algebra $C = v(\overline{C})$ such that $\overline{C} = C/IC$.

Proof. Let \overline{C} be an ind-étale A/I -algebra. Consider the category \mathcal{C} of factorizations $A \rightarrow B \rightarrow \overline{C}$ where $A \rightarrow B$ is étale. (We ignore some set theoretical issues in this proof.) We will show that this category is directed and that $C = \operatorname{colim}_{\mathcal{C}} B$ is an ind-étale A -algebra such that $\overline{C} = C/IC$.

We first prove that \mathcal{C} is directed (Categories, Definition 4.19.1). The category is nonempty as $A \rightarrow A \rightarrow \overline{C}$ is an object. Suppose that $A \rightarrow B \rightarrow \overline{C}$ and $A \rightarrow B' \rightarrow \overline{C}$ are two objects of \mathcal{C} . Then $A \rightarrow B \otimes_A B' \rightarrow \overline{C}$ is another (use Algebra, Lemma 10.138.3). Suppose that $f, g : B \rightarrow B'$ are two maps between objects $A \rightarrow B \rightarrow \overline{C}$ and $A \rightarrow B' \rightarrow \overline{C}$ of \mathcal{C} . Then a coequalizer is $A \rightarrow B' \otimes_{f,B,g} B' \rightarrow \overline{C}$. This is an object of \mathcal{C} by Algebra, Lemmas 10.138.3 and 10.138.9. Thus the category \mathcal{C} is directed.

Write $\overline{C} = \operatorname{colim} \overline{B}_i$ as a filtered colimit with \overline{B}_i étale over A/I . For every i there exists $A \rightarrow B_i$ étale with $\overline{B}_i = B_i/IB_i$, see Algebra, Lemma 10.138.11. Thus $C \rightarrow \overline{C}$ is surjective. Since $C/IC \rightarrow \overline{C}$ is ind-étale (Lemma 46.7.5) we see that it is flat. Hence \overline{C} is a localization of C/IC at some multiplicative subset $S \subset C/IC$ (Algebra, Lemma 10.104.2). Take an $f \in C$ mapping to an element of $S \subset C/IC$. Choose $A \rightarrow B \rightarrow \overline{C}$ in \mathcal{C} and $g \in B$ mapping to f in the colimit. Then we see that $A \rightarrow B_g \rightarrow \overline{C}$ is an object of \mathcal{C} as well. Thus f is an invertible element of C . It follows that $C/IC = \overline{C}$.

Next, we claim that for an ind-étale algebra D over A we have

$$\operatorname{Mor}_A(D, C) = \operatorname{Mor}_{A/I}(D/ID, \overline{C})$$

Namely, let $D/ID \rightarrow \overline{C}$ be an A/I -algebra map. Write $D = \operatorname{colim}_{i \in I} D_i$ as a filtered colimit over a partially ordered set I with D_i étale over A . By choice of \mathcal{C} we obtain a transformation $I \rightarrow \mathcal{C}$ and hence a map $D \rightarrow C$ compatible with maps to \overline{C} . Whence the claim.

It follows that the functor v defined by the rule

$$\overline{C} \mapsto v(\overline{C}) = \operatorname{colim}_{A \rightarrow B \rightarrow \overline{C}} B$$

is a right adjoint to the base change functor u as required by the lemma. The functor v is fully faithful because $u \circ v = \operatorname{id}$ by construction, see Categories, Lemma 4.24.3. \square

46.8. Constructing ind-étale algebras

Let A be a ring. Recall that any étale ring map $A \rightarrow B$ is isomorphic to a standard smooth ring map of relative dimension 0. Such a ring map is of the form

$$A \longrightarrow A[x_1, \dots, x_n]/(f_1, \dots, f_n)$$

where the determinant of the $n \times n$ -matrix with entries $\partial f_i / \partial x_j$ is invertible in the quotient ring. See Algebra, Lemma 10.138.2.

Let $S(A)$ be the set of all *faithfully flat*¹ standard smooth A -algebras of relative dimension 0. Let $I(A)$ be the partially ordered (by inclusion) set of finite subsets E of $S(A)$. Note that $I(A)$ is a directed partially ordered set. For $E = \{A \rightarrow B_1, \dots, A \rightarrow B_n\}$ set

$$B_E = B_1 \otimes_A \dots \otimes_A B_n$$

¹In the presence of flatness, e.g., for smooth or étale ring maps, this just means that the induced map on spectra is surjective. See Algebra, Lemma 10.38.15.

Observe that B_E is a faithfully flat étale A -algebra. For $E \subset E'$, there is a canonical transition map $B_E \rightarrow B_{E'}$ of étale A -algebras. Namely, say $E = \{A \rightarrow B_1, \dots, A \rightarrow B_n\}$ and $E' = \{A \rightarrow B_1, \dots, A \rightarrow B_{n+m}\}$ then $B_E \rightarrow B_{E'}$ sends $b_1 \otimes \dots \otimes b_n$ to the element $b_1 \otimes \dots \otimes b_n \otimes 1 \otimes \dots \otimes 1$ of $B_{E'}$. This construction defines a system of faithfully flat étale A -algebras over $I(A)$ and we set

$$T(A) = \operatorname{colim}_{E \in I(A)} B_E$$

Observe that $T(A)$ is a faithfully flat ind-étale A -algebra (Algebra, Lemma 10.38.20). By construction given any faithfully flat étale A -algebra B there is a (non-unique) A -algebra map $B \rightarrow T(A)$. Namely, pick some $(A \rightarrow B_0) \in S(A)$ and an isomorphism $B \cong B_0$. Then the canonical coprojection

$$B \rightarrow B_0 \rightarrow T(A) = \operatorname{colim}_{E \in I(A)} B_E$$

is the desired map.

Lemma 46.8.1. *Given a ring A there exists a faithfully flat ind-étale A -algebra C such that every faithfully flat étale ring map $C \rightarrow B$ has a section.*

Proof. Set $T^1(A) = T(A)$ and $T^{n+1}(A) = T(T^n(A))$. Let

$$C = \operatorname{colim} T^n(A)$$

This algebra is faithfully flat over each $T^n(A)$ and in particular over A , see Algebra, Lemma 10.38.20. Moreover, C is ind-étale over A by Lemma 46.7.4. If $C \rightarrow B$ is étale, then there exists an n and an étale ring map $T^n(A) \rightarrow B'$ such that $B = C \otimes_{T^n(A)} B'$, see Algebra, Lemma 10.138.3. If $C \rightarrow B$ is faithfully flat, then $\operatorname{Spec}(B) \rightarrow \operatorname{Spec}(C) \rightarrow \operatorname{Spec}(T^n(A))$ is surjective, hence $\operatorname{Spec}(B') \rightarrow \operatorname{Spec}(T^n(A))$ is surjective. In other words, $T^n(A) \rightarrow B'$ is faithfully flat. By our construction, there is a $T^n(A)$ -algebra map $B' \rightarrow T^{n+1}(A)$. This induces a C -algebra map $B \rightarrow C$ which finishes the proof. \square

Remark 46.8.2. Let A be a ring. Let κ be an infinite cardinal bigger or equal than the cardinality of A . Then the cardinality of $T(A)$ is at most κ . Namely, each B_E has cardinality at most κ and the index set $I(A)$ has cardinality at most κ as well. Thus the result follows as $\kappa \otimes \kappa = \kappa$, see Sets, Section 3.6. It follows that the ring constructed in the proof of Lemma 46.8.1 has cardinality at most κ as well.

Remark 46.8.3. The construction $A \mapsto T(A)$ is functorial in the following sense: If $A \rightarrow A'$ is a ring map, then we can construct a commutative diagram

$$\begin{array}{ccc} A & \longrightarrow & T(A) \\ \downarrow & & \downarrow \\ A' & \longrightarrow & T(A') \end{array}$$

Namely, given $(A \rightarrow A[x_1, \dots, x_n]/(f_1, \dots, f_n))$ in $S(A)$ we can use the ring map $\varphi : A \rightarrow A'$ to obtain a corresponding element $(A' \rightarrow A'[x_1, \dots, x_n]/(f_1^\varphi, \dots, f_n^\varphi))$ of $S(A')$ where f^φ means the polynomial obtained by applying φ to the coefficients of the polynomial f . Moreover, there is a commutative diagram

$$\begin{array}{ccc} A & \longrightarrow & A[x_1, \dots, x_n]/(f_1, \dots, f_n) \\ \downarrow & & \downarrow \\ A' & \longrightarrow & A'[x_1, \dots, x_n]/(f_1^\varphi, \dots, f_n^\varphi) \end{array}$$

which is a in the category of rings. For $E \subset S(A)$ finite, set $E' = \varphi(E)$ and define $B_E \rightarrow B_{E'}$ in the obvious manner. Taking the colimit gives the desired map $T(A) \rightarrow T(A')$, see Categories, Lemma 4.14.7.

Lemma 46.8.4. *Let A be a ring such that every faithfully flat étale ring map $A \rightarrow B$ has a section. Then the same is true for every quotient ring A/I .*

Proof. Omitted. □

Lemma 46.8.5. *Let A be a ring such that every faithfully flat étale ring map $A \rightarrow B$ has a section. Then every local ring of A at a maximal ideal is strictly henselian.*

Proof. Let \mathfrak{m} be a maximal ideal of A . Let $A \rightarrow B$ be an étale ring map and let $\mathfrak{q} \subset B$ be a prime lying over \mathfrak{m} . By the description of the strict henselization $A_{\mathfrak{m}}^{sh}$ in Algebra, Lemma 10.145.27 it suffices to show that $A_{\mathfrak{m}} = B_{\mathfrak{q}}$. Note that there are finitely many primes $\mathfrak{q} = \mathfrak{q}_1, \mathfrak{q}_2, \dots, \mathfrak{q}_n$ lying over \mathfrak{m} and there are no specializations between them as an étale ring map is quasi-finite, see Algebra, Lemma 10.138.6. Thus \mathfrak{q}_i is a maximal ideal and we can find $g \in \mathfrak{q}_2 \cap \dots \cap \mathfrak{q}_n$, $g \notin \mathfrak{q}_1$ (Algebra, Lemma 10.14.2). After replacing B by B_g we see that \mathfrak{q} is the only prime of B lying over \mathfrak{m} . The image $U \subset \text{Spec}(A)$ of $\text{Spec}(B) \rightarrow \text{Spec}(A)$ is open (Algebra, Proposition 10.40.8). Thus the complement $\text{Spec}(A) \setminus U$ is closed and we can find $f \in A$, $f \notin \mathfrak{p}$ such that $\text{Spec}(A) = U \cup D(f)$. The ring map $A \rightarrow B \times A_f$ is faithfully flat and étale, hence has a section $\sigma : B \times A_f \rightarrow A$ by assumption on A . Observe that σ is étale, hence flat as a map between étale A -algebras (Algebra, Lemma 10.138.9). Since \mathfrak{q} is the only prime of $B \times A_f$ lying over A we find that $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}}$ has a section which is also flat. Thus $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}} \rightarrow A_{\mathfrak{p}}$ are flat local ring maps whose composition is the identity. Since a flat local homomorphism of local rings is injective we conclude these maps are isomorphisms as desired. □

Lemma 46.8.6. *Let A be a ring such that every faithfully flat étale ring map $A \rightarrow B$ has a section. Let $Z \subset \text{Spec}(A)$ be a closed subscheme of the form $D(f) \cap V(I)$ and let $A \rightarrow A_{\tilde{Z}}$ be as constructed in Lemma 46.5.1. Then every faithfully flat étale ring map $A_{\tilde{Z}} \rightarrow C$ has a section.*

Proof. There exists an étale ring map $A \rightarrow B'$ such that $C = B' \otimes_A A_{\tilde{Z}}$ as $A_{\tilde{Z}}$ -algebras. The image $U' \subset \text{Spec}(A)$ of $\text{Spec}(B') \rightarrow \text{Spec}(A)$ is open and contains $V(I)$, hence we can find $f \in I$ such that $\text{Spec}(A) = U' \cup D(f)$. Then $A \rightarrow B' \times A_f$ is étale and faithfully flat. By assumption there is a section $B' \times A_f \rightarrow A$. Localizing we obtain the desired section $C \rightarrow A_{\tilde{Z}}$. □

Lemma 46.8.7. *Let $A \rightarrow B$ be a ring map inducing algebraic extensions on residue fields. There exists a commutative diagram*

$$\begin{array}{ccc} B & \longrightarrow & D \\ \uparrow & & \uparrow \\ A & \longrightarrow & C \end{array}$$

with the following properties:

- (1) $A \rightarrow C$ is faithfully flat and ind-étale,
- (2) $B \rightarrow D$ is faithfully flat and ind-étale,
- (3) $\text{Spec}(C)$ is w -local,

- (4) $\text{Spec}(D)$ is w -local,
- (5) $\text{Spec}(D) \rightarrow \text{Spec}(C)$ is w -local,
- (6) the set of closed points of $\text{Spec}(D)$ is the inverse image of the set of closed points of $\text{Spec}(C)$,
- (7) the set of closed points of $\text{Spec}(C)$ surjects onto $\text{Spec}(A)$,
- (8) the set of closed points of $\text{Spec}(D)$ surjects onto $\text{Spec}(B)$,
- (9) for $\mathfrak{m} \subset C$ maximal the local ring $C_{\mathfrak{m}}$ is strictly henselian.

Proof. There is a faithfully flat, ind-Zariski ring map $A \rightarrow A'$ such that $\text{Spec}(A')$ is w -local and such that the set of closed points of $\text{Spec}(A')$ maps onto $\text{Spec}(A)$, see Lemma 46.5.3. Let $I \subset A'$ be the ideal such that $V(I)$ is the set of closed points of $\text{Spec}(A')$. Choose $A' \rightarrow C'$ as in Lemma 46.8.1. Note that the local rings $C'_{\mathfrak{m}'}$ at maximal ideals $\mathfrak{m}' \subset C'$ are strictly henselian by Lemma 46.8.5. We apply Lemma 46.5.8 to $A' \rightarrow C'$ and $I \subset A'$ to get $C' \rightarrow C$ with $C'/IC' \cong C/IC$. Note that since $A' \rightarrow C'$ is faithfully flat, $\text{Spec}(C'/IC')$ surjects onto the set of closed points of A' and in particular onto $\text{Spec}(A)$. Moreover, as $V(IC) \subset \text{Spec}(C)$ is the set of closed points of C and $C' \rightarrow C$ is ind-Zariski (and identifies local rings) we obtain properties (1), (3), (7), and (9).

Denote $J \subset C$ the ideal such that $V(J)$ is the set of closed points of $\text{Spec}(C)$. Set $D' = B \otimes_A C$. The ring map $C \rightarrow D'$ induces algebraic residue field extensions. Keep in mind that since $V(J) \rightarrow \text{Spec}(A)$ is surjective the map $T = V(JD) \rightarrow \text{Spec}(B)$ is surjective too. Apply Lemma 46.5.8 to $C \rightarrow D'$ and $J \subset C$ to get $D' \rightarrow D$ with $D'/JD' \cong D/JD$. All of the remaining properties given in the lemma are immediate from the results of Lemma 46.5.8. \square

46.9. Weakly étale versus pro-étale

Recall that a ring homomorphism $A \rightarrow B$ is *weakly étale* if $A \rightarrow B$ is flat and $B \otimes_A B \rightarrow B$ is flat. We have proved some properties of such ring maps in More on Algebra, Section 15.67. In particular, if $A \rightarrow B$ is a local homomorphism, and A is a strictly henselian local rings, then $A = B$, see More on Algebra, Theorem 15.67.24. Using this theorem and the work we've done above we obtain the following structure theorem for weakly étale ring maps.

Proposition 46.9.1. *Let $A \rightarrow B$ be a weakly étale ring map. Then there exists a faithfully flat, ind-étale ring map $B \rightarrow B'$ such that $A \rightarrow B'$ is ind-étale.*

Proof. The ring map $A \rightarrow B$ induces (separable) algebraic extensions of residue fields, see More on Algebra, Lemma 15.67.16. Thus we may apply Lemma 46.8.7 and choose a diagram

$$\begin{array}{ccc} B & \longrightarrow & D \\ \uparrow & & \uparrow \\ A & \longrightarrow & C \end{array}$$

with the properties as listed in the lemma. Note that $C \rightarrow D$ is weakly étale by More on Algebra, Lemma 15.67.11. Pick a maximal ideal $\mathfrak{m} \subset D$. By construction this lies over a maximal ideal $\mathfrak{m}' \subset C$. By More on Algebra, Theorem 15.67.24 the ring map $C_{\mathfrak{m}'} \rightarrow D_{\mathfrak{m}}$ is an isomorphism. As every point of $\text{Spec}(C)$ specializes to a closed point we conclude that $C \rightarrow D$ identifies local rings. Thus Proposition 46.6.6 applies to the ring map $C \rightarrow D$. Pick $D \rightarrow D'$ faithfully flat and ind-Zariski

such that $C \rightarrow D'$ is ind-Zariski. Then $B \rightarrow D'$ is a solution to the problem posed in the proposition. \square

46.10. Constructing w-contractible covers

In this section we construct w-contractible covers of affine schemes.

Definition 46.10.1. Let A be a ring. We say A is *w-contractible* if every faithfully flat weakly-étale ring map $A \rightarrow B$ has a section.

We remark that by Proposition 46.9.1 an equivalent definition would be to ask that every faithfully flat, ind-étale ring map $A \rightarrow B$ has a section. Here is a key observation that will allow us to construct w-contractible rings.

Lemma 46.10.2. *Let A be a ring. The following are equivalent*

- (1) A is w-contractible,
- (2) every faithfully flat, ind-étale ring map $A \rightarrow B$ has a section, and
- (3) A satisfies
 - (a) $\text{Spec}(A)$ is w-local,
 - (b) $\pi_0(\text{Spec}(A))$ is extremally disconnected, and
 - (c) for every maximal ideal $\mathfrak{m} \subset A$ the local ring $A_{\mathfrak{m}}$ is strictly henselian.

Proof. The equivalence of (1) and (2) follows immediately from Proposition 46.9.1.

Assume (3)(a), (3)(b), and (3)(c). Let $A \rightarrow B$ be faithfully flat and ind-étale. We will use without further mention the fact that a flat map $A \rightarrow B$ is faithfully flat if and only if every closed point of $\text{Spec}(A)$ is in the image of $\text{Spec}(B) \rightarrow \text{Spec}(A)$. We will show that $A \rightarrow B$ has a section.

Let $I \subset A$ be an ideal such that $V(I) \subset \text{Spec}(A)$ is the set of closed points of $\text{Spec}(A)$. We may replace B by the ring C constructed in Lemma 46.5.8 for $A \rightarrow B$ and $I \subset A$. Thus we may assume $\text{Spec}(B)$ is w-local such that the set of closed points of $\text{Spec}(B)$ is $V(IB)$. In this case $A \rightarrow B$ identifies local rings by condition (3)(c) as it suffices to check this at maximal ideals of B which lie over maximal ideals of A . Thus $A \rightarrow B$ has a section by Lemma 46.6.7.

Assume (1) or equivalently (2). We have (3)(c) by Lemma 46.8.5. Properties (3)(a) and (3)(b) follow from Lemma 46.6.7. \square

Proposition 46.10.3. *For every ring A there exists a faithfully flat, ind-étale ring map $A \rightarrow D$ such that D is w-contractible.*

Proof. Applying Lemma 46.8.7 to $\text{id}_A : A \rightarrow A$ we find a faithfully flat, ind-étale ring map $A \rightarrow C$ such that C is w-local and such that every local ring at a maximal ideal of C is strictly henselian. Choose an extremally disconnected space T and a surjective continuous map $T \rightarrow \pi_0(\text{Spec}(C))$, see Topology, Lemma 5.25.9. Note that T is profinite. Apply Lemma 46.6.2 to find an ind-Zariski ring map $C \rightarrow D$ such that $\pi_0(\text{Spec}(D)) \rightarrow \pi_0(\text{Spec}(C))$ realizes $T \rightarrow \pi_0(\text{Spec}(C))$ and such that

$$\begin{array}{ccc} \text{Spec}(D) & \longrightarrow & \pi_0(\text{Spec}(D)) \\ \downarrow & & \downarrow \\ \text{Spec}(C) & \longrightarrow & \pi_0(\text{Spec}(C)) \end{array}$$

is cartesian in the category of topological spaces. Note that $\text{Spec}(D)$ is w-local, that $\text{Spec}(D) \rightarrow \text{Spec}(C)$ is w-local, and that the set of closed points of $\text{Spec}(D)$ is the inverse image of the set of closed points of $\text{Spec}(C)$, see Lemma 46.2.5. Thus it is still true that the local rings of D at its maximal ideals are strictly henselian (as they are isomorphic to the local rings at the corresponding maximal ideals of C). It follows from Lemma 46.10.2 that D is w-contractible. \square

Remark 46.10.4. Let A be a ring. Let κ be an infinite cardinal bigger or equal than the cardinality of A . Then the cardinality of the ring D constructed in Proposition 46.10.3 is at most

$$\kappa^{2^{2^{2^\kappa}}}.$$

Namely, the ring map $A \rightarrow D$ is constructed as a composition

$$A \rightarrow A_w = A' \rightarrow C' \rightarrow C \rightarrow D.$$

Here the first three steps of the construction are carried out in the first paragraph of the proof of Lemma 46.8.7. For the first step we have $|A_w| \leq \kappa$ by Remark 46.5.4. We have $|C'| \leq \kappa$ by Remark 46.8.2. Then $|C| \leq \kappa$ because C is a localization of $(C')_w$ (it is constructed from C' by an application of Lemma 46.5.7 in the proof of Lemma 46.5.8). Thus C has at most 2^κ maximal ideals. Finally, the ring map $C \rightarrow D$ identifies local rings and the cardinality of the set of maximal ideals of D is at most $2^{2^{2^\kappa}}$ by Topology, Remark 5.25.10. Since $D \subset \prod_{\mathfrak{m} \subset D} D_{\mathfrak{m}}$ we see that D has at most the size displayed above.

Lemma 46.10.5. *Let $A \rightarrow B$ be a quasi-finite and finitely presented ring map. If the residue fields of A are separably algebraically closed and $\text{Spec}(A)$ is extremally disconnected, then $\text{Spec}(B)$ is extremally disconnected.*

Proof. Set $X = \text{Spec}(A)$ and $Y = \text{Spec}(B)$. Choose a finite partition $X = \coprod X_i$ and $X'_i \rightarrow X_i$ as in Étale Cohomology, Lemma 44.70.3. Because X is extremally disconnected, every constructible locally closed subset is open and closed, hence we see that X is topologically the disjoint union of the strata X_i . Thus we may replace X by the X_i and assume there exists a surjective finite locally free morphism $X' \rightarrow X$ such that $(X' \times_X Y)_{red}$ is isomorphic to a finite disjoint union of copies of X'_{red} . Picture

$$\begin{array}{ccc} \coprod_{i=1, \dots, r} X' & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X' & \longrightarrow & X \end{array}$$

The assumption on the residue fields of A implies that this diagram is a fibre product diagram on underlying sets of points (details omitted). Since X is extremally disconnected and X' is Hausdorff (Lemma 46.5.6), the continuous map $X' \rightarrow X$ has a continuous section σ . Then $\coprod_{i=1, \dots, r} \sigma(X) \rightarrow Y$ is a bijective continuous map. By Topology, Lemma 5.16.8 we see that it is a homeomorphism and the proof is done. \square

Lemma 46.10.6. *Let $A \rightarrow B$ be a finite and finitely presented ring map. If A is w-contractible, so is B .*

Proof. We will use the criterion of Lemma 46.10.2. Set $X = \text{Spec}(A)$ and $Y = \text{Spec}(B)$. As $Y \rightarrow X$ is a finite morphism, we see that the set of closed points Y_0 of Y is the inverse image of the set of closed points X_0 of X . Moreover, every point of Y specializes to a unique point of Y_0 as (a) this is true for X and (b) the map $X \rightarrow Y$ is separated. For every $y \in Y_0$ with image $x \in X_0$ we see that $\mathcal{O}_{Y,y}$ is strictly henselian by Algebra, Lemma 10.145.4 applied to $\mathcal{O}_{X,x} \rightarrow B \otimes_A \mathcal{O}_{X,x}$. It remains to show that Y_0 is extremally disconnected. To do this we look at $X_0 \times_X Y \rightarrow X_0$ where $X_0 \subset X$ is the reduced induced scheme structure. Note that the underlying topological space of $X_0 \times_X Y$ agrees with Y_0 . Now the desired result follows from Lemma 46.10.5. \square

Lemma 46.10.7. *Let A be a ring. Let $Z \subset \text{Spec}(A)$ be a closed subset of the form $Z = V(f_1, \dots, f_r)$. Set $B = A_{\tilde{Z}}$, see Lemma 46.5.1. If A is w-contractible, so is B .*

Proof. Let $A_{\tilde{Z}} \rightarrow B$ be a weakly étale faithfully flat ring map. Consider the ring map

$$A \longrightarrow A_{f_1} \times \dots \times A_{f_r} \times B$$

this is faithful flat and weakly étale. If A is w-contractible, then there is a section σ . Consider the morphism

$$\text{Spec}(A_{\tilde{Z}}) \rightarrow \text{Spec}(A) \xrightarrow{\text{Spec}(\sigma)} \coprod \text{Spec}(A_{f_i}) \amalg \text{Spec}(B)$$

Every point of $Z \subset \text{Spec}(A_{\tilde{Z}})$ maps into the component $\text{Spec}(B)$. Since every point of $\text{Spec}(A_{\tilde{Z}})$ specializes to a point of Z we find a morphism $\text{Spec}(A_{\tilde{Z}}) \rightarrow \text{Spec}(B)$ as desired. \square

46.11. The pro-étale site

The (small) pro-étale site of a scheme has some remarkable properties. In particular, it has enough w-contractible objects which implies a number of useful consequences for the derived category of abelian sheaves and for inverse systems of sheaves. Thus it is well adapted to deal with some of the intricacies of working with ℓ -adic sheaves.

On the other hand, the pro-étale topology is a bit like the fpqc topology (see Topologies, Section 33.8) in that the topos of sheaves on the small pro-étale site of a scheme depends on the choice of the underlying category of schemes. Thus we cannot speak of *the* pro-étale topos of a scheme. However, it will be true that the cohomology groups of a sheaf are unchanged if we enlarge our underlying category of schemes.

Another curiosity is that we define pro-étale coverings using weakly étale morphisms of schemes, see More on Morphisms, Section 36.44. The reason is that, on the one hand, it is somewhat awkward to define the notion of a pro-étale morphism of schemes, and on the other, Proposition 46.9.1 assures us that we obtain the same sheaves with the definition that follows.

Definition 46.11.1. Let T be a scheme. A *pro-étale covering* of T is a family of morphisms $\{f_i : T_i \rightarrow T\}_{i \in I}$ of schemes such that each f_i is weakly-étale and such that for every affine open $U \subset T$ there exists $n \geq 0$, a map $a : \{1, \dots, n\} \rightarrow I$ and affine opens $V_j \subset T_{a(j)}$, $j = 1, \dots, n$ with $\bigcup_{j=1}^n f_{a(j)}(V_j) = U$.

To be sure this condition implies that $T = \bigcup f_i(T_i)$. Here is a lemma that will allow us to recognize pro-étale coverings. It will also allow us to reduce many lemmas about pro-étale coverings to the corresponding results for fpqc coverings.

Lemma 46.11.2. *Let T be a scheme. Let $\{f_i : T_i \rightarrow T\}_{i \in I}$ be a family of morphisms of schemes with target T . The following are equivalent*

- (1) $\{f_i : T_i \rightarrow T\}_{i \in I}$ is a pro-étale covering,
- (2) each f_i is weakly étale and $\{f_i : T_i \rightarrow T\}_{i \in I}$ is an fpqc covering,
- (3) each f_i is weakly étale and for every affine open $U \subset T$ there exist quasi-compact opens $U_i \subset T_i$ which are almost all empty, such that $U = \bigcup f_i(U_i)$,
- (4) each f_i is weakly étale and there exists an affine open covering $T = \bigcup_{\alpha \in A} U_\alpha$ and for each $\alpha \in A$ there exist $i_{\alpha,1}, \dots, i_{\alpha,n(\alpha)} \in I$ and quasi-compact opens $U_{\alpha,j} \subset T_{i_{\alpha,j}}$ such that $U_\alpha = \bigcup_{j=1, \dots, n(\alpha)} f_{i_{\alpha,j}}(U_{\alpha,j})$.

If T is quasi-separated, these are also equivalent to

- (5) each f_i is weakly étale, and for every $t \in T$ there exist $i_1, \dots, i_n \in I$ and quasi-compact opens $U_j \subset T_{i_j}$ such that $\bigcup_{j=1, \dots, n} f_{i_j}(U_j)$ is a (not necessarily open) neighbourhood of t in T .

Proof. The equivalence of (1) and (2) is immediate from the definitions. Hence the lemma follows from Topologies, Lemma 33.8.2. \square

Lemma 46.11.3. *Any étale covering and any Zariski covering is a pro-étale covering.*

Proof. This follows from the corresponding result for fpqc coverings (Topologies, Lemma 33.8.6), Lemma 46.11.2, and the fact that an étale morphism is a weakly étale morphism, see More on Morphisms, Lemma 36.44.9. \square

Lemma 46.11.4. *Let T be a scheme.*

- (1) If $T' \rightarrow T$ is an isomorphism then $\{T' \rightarrow T\}$ is a pro-étale covering of T .
- (2) If $\{T_i \rightarrow T\}_{i \in I}$ is a pro-étale covering and for each i we have a pro-étale covering $\{T_{ij} \rightarrow T_i\}_{j \in J_i}$, then $\{T_{ij} \rightarrow T\}_{i \in I, j \in J_i}$ is a pro-étale covering.
- (3) If $\{T_i \rightarrow T\}_{i \in I}$ is a pro-étale covering and $T' \rightarrow T$ is a morphism of schemes then $\{T' \times_T T_i \rightarrow T'\}_{i \in I}$ is a pro-étale covering.

Proof. This follows from the fact that composition and base changes of weakly étale morphisms are weakly étale (More on Morphisms, Lemmas 36.44.5 and 36.44.6), Lemma 46.11.2, and the corresponding results for fpqc coverings, see Topologies, Lemma 33.8.7. \square

Lemma 46.11.5. *Let T be an affine scheme. Let $\{T_i \rightarrow T\}_{i \in I}$ be a pro-étale covering of T . Then there exists a pro-étale covering $\{U_j \rightarrow T\}_{j=1, \dots, n}$ which is a refinement of $\{T_i \rightarrow T\}_{i \in I}$ such that each U_j is an affine scheme. Moreover, we may choose each U_j to be open affine in one of the T_i .*

Proof. This follows directly from the definition. \square

Thus we define the corresponding standard coverings of affines as follows.

Definition 46.11.6. Let T be an affine scheme. A *standard pro-étale covering* of T is a family $\{f_i : T_i \rightarrow T\}_{i=1, \dots, n}$ with each T_j is affine, each f_i is weakly étale, and $T = \bigcup f_i(T_i)$.

We interrupt the discussion for an explanation of the notion of w-contractible rings in terms of pro-étale coverings.

Lemma 46.11.7. *Let $T = \text{Spec}(A)$ be an affine scheme. The following are equivalent*

- (1) *A is w-contractible, and*
- (2) *every pro-étale covering of T can be refined by a Zariski covering of the form $T = \coprod_{i=1, \dots, n} U_i$.*

Proof. Assume A is w-contractible. By Lemma 46.11.5 it suffices to prove we can refine every standard pro-étale covering $\{f_i : T_i \rightarrow T\}_{i=1, \dots, n}$ by a Zariski covering of T . The morphism $\coprod T_i \rightarrow T$ is a surjective weakly étale morphism of affine schemes. Hence by Definition 46.10.1 there exists a morphism $\sigma : T \rightarrow \coprod T_i$ over T . Then the Zariski covering $T = \coprod \sigma^{-1}(T_i)$ refines $\{f_i : T_i \rightarrow T\}$.

Conversely, assume (2). If $A \rightarrow B$ is faithfully flat and weakly étale, then $\{\text{Spec}(B) \rightarrow T\}$ is a pro-étale covering. Hence there exists a Zariski covering $T = \coprod U_i$ and morphisms $U_i \rightarrow \text{Spec}(B)$ over T . Since $T = \coprod U_i$ we obtain $T \rightarrow \text{Spec}(B)$, i.e., an A -algebra map $B \rightarrow A$. This means A is w-contractible. \square

We follow the general outline given in Topologies, Section 33.2 for constructing the big pro-étale site we will be working with. However, because we need a bit larger rings to accommodate for the size of certain constructions we modify the constructions slightly.

Definition 46.11.8. *A big pro-étale site is any site $Sch_{\text{pro-étale}}$ as in Sites, Definition 7.6.2 constructed as follows:*

- (1) Choose any set of schemes S_0 , and any set of pro-étale coverings Cov_0 among these schemes.
- (2) Change the function *Bound* of Sets, Equation (3.9.1.1) into

$$\text{Bound}(\kappa) = \max\{\kappa^{2^{2^{2^\kappa}}}, \kappa^{\aleph_0}, \kappa^+\}.$$

- (3) As underlying category take any category Sch_α constructed as in Sets, Lemma 3.9.2 starting with the set S_0 and the function *Bound*.
- (4) Choose any set of coverings as in Sets, Lemma 3.11.1 starting with the category Sch_α and the class of pro-étale coverings, and the set Cov_0 chosen above.

See the remarks following Topologies, Definition 33.3.5 for motivation and explanation regarding the definition of big sites.

Before we continue with the introduction of the big and small pro-étale sites of a scheme, let us point out that (1) our category contains many weakly contractible objects, and (2) the topology on a big pro-étale site $Sch_{\text{pro-étale}}$ is in some sense induced from the pro-étale topology on the category of all schemes.

Lemma 46.11.9. *Let $Sch_{\text{pro-étale}}$ be a big pro-étale site as in Definition 46.11.8. Let $T = \text{Spec}(A)$ be an affine object of $Sch_{\text{pro-étale}}$. If A is w-contractible, then T is a weakly contractible (Sites, Definition 7.39.2) object of $Sch_{\text{pro-étale}}$.*

Proof. Let $\mathcal{F} \rightarrow \mathcal{G}$ be a surjection of sheaves on $Sch_{\text{pro-étale}}$. Let $s \in \mathcal{G}(T)$. We have to show that s is in the image of $\mathcal{F}(T) \rightarrow \mathcal{G}(T)$. We can find a covering $\{T_i \rightarrow T\}$ of $Sch_{\text{pro-étale}}$ such that s lifts to a section of \mathcal{F} over T_i (Sites, Definition

7.12.1). By Lemma 46.11.7 we can refine $\{T_i \rightarrow T\}$ by a Zariski covering of the form $T = \coprod_{j=1, \dots, m} V_j$. Hence we get $t_j \in \mathcal{F}(U_j)$ mapping to $s|_{U_j}$. Since Zariski coverings are coverings in $Sch_{pro\text{-}\acute{e}tale}$ (Lemma 46.11.3) we conclude that $\mathcal{F}(T) = \coprod \mathcal{F}(U_j)$. Thus, taking $t = (t_1, \dots, t_m) \in \mathcal{F}(T)$ is a section mapping to s . \square

Lemma 46.11.10. *Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site as in Definition 46.11.8. For every object T of $Sch_{pro\text{-}\acute{e}tale}$ there exists a covering $\{T_i \rightarrow T\}$ in $Sch_{pro\text{-}\acute{e}tale}$ with each T_i affine and the spectrum of a w-contractible ring. In particular, T_i is weakly contractible in $Sch_{pro\text{-}\acute{e}tale}$.*

Proof. For those readers who do not care about set-theoretical issues this lemma is a trivial consequence of Lemma 46.11.9 and Proposition 46.10.3. Here are the details. Choose an affine open covering $T = \bigcup U_i$. Write $U_i = \text{Spec}(A_i)$. Choose faithfully flat, ind-étale ring maps $A_i \rightarrow D_i$ such that D_i is w-contractible as in Proposition 46.10.3. The family of morphisms $\{\text{Spec}(D_i) \rightarrow T\}$ is a pro-étale covering. If we can show that $\text{Spec}(D_i)$ is isomorphic to an object, say T_i , of $Sch_{pro\text{-}\acute{e}tale}$, then $\{T_i \rightarrow T\}$ will be combinatorially equivalent to a covering of $Sch_{pro\text{-}\acute{e}tale}$ by the construction of $Sch_{pro\text{-}\acute{e}tale}$ in Definition 46.11.8 and more precisely the application of Sets, Lemma 3.11.1 in the last step. To prove $\text{Spec}(D_i)$ is isomorphic to an object of $Sch_{pro\text{-}\acute{e}tale}$, it suffices to prove that $|D_i| \leq \text{Bound}(\text{Size}(T))$ by the construction of $Sch_{pro\text{-}\acute{e}tale}$ in Definition 46.11.8 and more precisely the application of Sets, Lemma 3.9.2 in step (3). Since $|A_i| \leq \text{size}(U_i) \leq \text{size}(T)$ by Sets, Lemmas 3.9.4 and 3.9.7 we get $|D_i| \leq \kappa^{2^{2^{\kappa}}}$ where $\kappa = \text{size}(T)$ by Remark 46.10.4. Thus by our choice of the function Bound in Definition 46.11.8 we win. \square

Lemma 46.11.11. *Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site as in Definition 46.11.8. Let $T \in \text{Ob}(Sch_{pro\text{-}\acute{e}tale})$. Let $\{T_i \rightarrow T\}_{i \in I}$ be an arbitrary pro-étale covering of T . There exists a covering $\{U_j \rightarrow T\}_{j \in J}$ of T in the site $Sch_{pro\text{-}\acute{e}tale}$ which refines $\{T_i \rightarrow T\}_{i \in I}$.*

Proof. Namely, we first let $\{V_k \rightarrow T\}$ be a covering as in Lemma 46.11.10. Then the pro-étale coverings $\{T_i \times_T V_k \rightarrow V_k\}$ can be refined by a finite disjoint open covering $V_k = V_{k,1} \amalg \dots \amalg V_{k,n_k}$, see Lemma 46.11.7. Then $\{V_{k,i} \rightarrow T\}$ is a covering of $Sch_{pro\text{-}\acute{e}tale}$ which refines $\{T_i \rightarrow T\}_{i \in I}$. \square

Definition 46.11.12. Let S be a scheme. Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site containing S .

- (1) The *big pro-étale site of S* , denoted $(Sch/S)_{pro\text{-}\acute{e}tale}$, is the site $Sch_{pro\text{-}\acute{e}tale}/S$ introduced in Sites, Section 7.24.
- (2) The *small pro-étale site of S* , which we denote $S_{pro\text{-}\acute{e}tale}$, is the full subcategory of $(Sch/S)_{pro\text{-}\acute{e}tale}$ whose objects are those U/S such that $U \rightarrow S$ is weakly étale. A covering of $S_{pro\text{-}\acute{e}tale}$ is any covering $\{U_i \rightarrow U\}$ of $(Sch/S)_{pro\text{-}\acute{e}tale}$ with $U \in \text{Ob}(S_{pro\text{-}\acute{e}tale})$.
- (3) The *big affine pro-étale site of S* , denoted $(Aff/S)_{pro\text{-}\acute{e}tale}$, is the full subcategory of $(Sch/S)_{pro\text{-}\acute{e}tale}$ whose objects are affine U/S . A covering of $(Aff/S)_{pro\text{-}\acute{e}tale}$ is any covering $\{U_i \rightarrow U\}$ of $(Sch/S)_{pro\text{-}\acute{e}tale}$ which is a standard pro-étale covering.

It is not completely clear that the small pro-étale site and the big affine pro-étale site are sites. We check this now.

Lemma 46.11.13. *Let S be a scheme. Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site containing S . Both $S_{pro\text{-}\acute{e}tale}$ and $(Aff/S)_{pro\text{-}\acute{e}tale}$ are sites.*

Proof. Let us show that $S_{pro\text{-}\acute{e}tale}$ is a site. It is a category with a given set of families of morphisms with fixed target. Thus we have to show properties (1), (2) and (3) of Sites, Definition 7.6.2. Since $(Sch/S)_{pro\text{-}\acute{e}tale}$ is a site, it suffices to prove that given any covering $\{U_i \rightarrow U\}$ of $(Sch/S)_{pro\text{-}\acute{e}tale}$ with $U \in \text{Ob}(S_{pro\text{-}\acute{e}tale})$ we also have $U_i \in \text{Ob}(S_{pro\text{-}\acute{e}tale})$. This follows from the definitions as the composition of weakly étale morphisms is weakly étale.

To show that $(Aff/S)_{pro\text{-}\acute{e}tale}$ is a site, reasoning as above, it suffices to show that the collection of standard pro-étale coverings of affines satisfies properties (1), (2) and (3) of Sites, Definition 7.6.2. This follows from Lemma 46.11.2 and the corresponding result for standard fpqc coverings (Topologies, Lemma 33.8.10). \square

Lemma 46.11.14. *Let S be a scheme. Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site containing S . Let Sch be the category of all schemes.*

- (1) *The categories $Sch_{pro\text{-}\acute{e}tale}$, $(Sch/S)_{pro\text{-}\acute{e}tale}$, $S_{pro\text{-}\acute{e}tale}$, and $(Aff/S)_{pro\text{-}\acute{e}tale}$ have fibre products agreeing with fibre products in Sch .*
- (2) *The categories $Sch_{pro\text{-}\acute{e}tale}$, $(Sch/S)_{pro\text{-}\acute{e}tale}$, $S_{pro\text{-}\acute{e}tale}$ have equalizers agreeing with equalizers in Sch .*
- (3) *The categories $(Sch/S)_{pro\text{-}\acute{e}tale}$, and $S_{pro\text{-}\acute{e}tale}$ both have a final object, namely S/S .*
- (4) *The category $Sch_{pro\text{-}\acute{e}tale}$ has a final object agreeing with the final object of Sch , namely $\text{Spec}(\mathbf{Z})$.*

Proof. The category $Sch_{pro\text{-}\acute{e}tale}$ contains $\text{Spec}(\mathbf{Z})$ and is closed under products and fibre products by construction, see Sets, Lemma 3.9.9. Suppose we have $U \rightarrow S$, $V \rightarrow U$, $W \rightarrow U$ morphisms of schemes with $U, V, W \in \text{Ob}(Sch_{pro\text{-}\acute{e}tale})$. The fibre product $V \times_U W$ in $Sch_{pro\text{-}\acute{e}tale}$ is a fibre product in Sch and is the fibre product of V/S with W/S over U/S in the category of all schemes over S , and hence also a fibre product in $(Sch/S)_{pro\text{-}\acute{e}tale}$. This proves the result for $(Sch/S)_{pro\text{-}\acute{e}tale}$. If $U \rightarrow S$, $V \rightarrow U$ and $W \rightarrow U$ are weakly étale then so is $V \times_U W \rightarrow S$ (see More on Morphisms, Section 36.44) and hence we get fibre products for $S_{pro\text{-}\acute{e}tale}$. If U, V, W are affine, so is $V \times_U W$ and hence we get fibre products for $(Aff/S)_{pro\text{-}\acute{e}tale}$.

Let $a, b : U \rightarrow V$ be two morphisms in $Sch_{pro\text{-}\acute{e}tale}$. In this case the equalizer of a and b (in the category of schemes) is

$$V \times_{\Delta_{V/\text{Spec}(\mathbf{Z}), V \times_{\text{Spec}(\mathbf{Z})} V, (a,b)}} (U \times_{\text{Spec}(\mathbf{Z})} U)$$

which is an object of $Sch_{pro\text{-}\acute{e}tale}$ by what we saw above. Thus $Sch_{pro\text{-}\acute{e}tale}$ has equalizers. If a and b are morphisms over S , then the equalizer (in the category of schemes) is also given by

$$V \times_{\Delta_{V/S, V \times_S V, (a,b)}} (U \times_S U)$$

hence we see that $(Sch/S)_{pro\text{-}\acute{e}tale}$ has equalizers. Moreover, if U and V are weakly étale over S , then so is the equalizer above as a fibre product of schemes weakly étale over S . Thus $S_{pro\text{-}\acute{e}tale}$ has equalizers. The statements on final objects is clear. \square

Next, we check that the big affine pro-étale site defines the same topos as the big pro-étale site.

Lemma 46.11.15. *Let S be a scheme. Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site containing S . The functor $(Aff/S)_{pro\text{-}\acute{e}tale} \rightarrow (Sch/S)_{pro\text{-}\acute{e}tale}$ is a special cocontinuous functor. Hence it induces an equivalence of topoi from $Sh((Aff/S)_{pro\text{-}\acute{e}tale})$ to $Sh((Sch/S)_{pro\text{-}\acute{e}tale})$.*

Proof. The notion of a special cocontinuous functor is introduced in Sites, Definition 7.28.2. Thus we have to verify assumptions (1) – (5) of Sites, Lemma 7.28.1. Denote the inclusion functor $u : (Aff/S)_{pro\text{-}\acute{e}tale} \rightarrow (Sch/S)_{pro\text{-}\acute{e}tale}$. Being cocontinuous just means that any pro-étale covering of T/S , T affine, can be refined by a standard pro-étale covering of T . This is the content of Lemma 46.11.5. Hence (1) holds. We see u is continuous simply because a standard pro-étale covering is a pro-étale covering. Hence (2) holds. Parts (3) and (4) follow immediately from the fact that u is fully faithful. And finally condition (5) follows from the fact that every scheme has an affine open covering. \square

Lemma 46.11.16. *Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site. Let $f : T \rightarrow S$ be a morphism in $Sch_{pro\text{-}\acute{e}tale}$. The functor $T_{pro\text{-}\acute{e}tale} \rightarrow (Sch/S)_{pro\text{-}\acute{e}tale}$ is cocontinuous and induces a morphism of topoi*

$$i_f : Sh(T_{pro\text{-}\acute{e}tale}) \longrightarrow Sh((Sch/S)_{pro\text{-}\acute{e}tale})$$

For a sheaf \mathcal{G} on $(Sch/S)_{pro\text{-}\acute{e}tale}$ we have the formula $(i_f^{-1}\mathcal{G})(U/T) = \mathcal{G}(U/S)$. The functor i_f^{-1} also has a left adjoint $i_{f,!}$ which commutes with fibre products and equalizers.

Proof. Denote the functor $u : T_{pro\text{-}\acute{e}tale} \rightarrow (Sch/S)_{pro\text{-}\acute{e}tale}$. In other words, given a weakly étale morphism $j : U \rightarrow T$ corresponding to an object of $T_{pro\text{-}\acute{e}tale}$ we set $u(U \rightarrow T) = (f \circ j : U \rightarrow S)$. This functor commutes with fibre products, see Lemma 46.11.14. Moreover, $T_{pro\text{-}\acute{e}tale}$ has equalizers and u commutes with them by Lemma 46.11.14. It is clearly cocontinuous. It is also continuous as u transforms coverings to coverings and commutes with fibre products. Hence the lemma follows from Sites, Lemmas 7.20.5 and 7.20.6. \square

Lemma 46.11.17. *Let S be a scheme. Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site containing S . The inclusion functor $S_{pro\text{-}\acute{e}tale} \rightarrow (Sch/S)_{pro\text{-}\acute{e}tale}$ satisfies the hypotheses of Sites, Lemma 7.20.8 and hence induces a morphism of sites*

$$\pi_S : (Sch/S)_{pro\text{-}\acute{e}tale} \longrightarrow S_{pro\text{-}\acute{e}tale}$$

and a morphism of topoi

$$i_S : Sh(S_{pro\text{-}\acute{e}tale}) \longrightarrow Sh((Sch/S)_{pro\text{-}\acute{e}tale})$$

such that $\pi_S \circ i_S = id$. Moreover, $i_S = i_{id_S}$ with i_{id_S} as in Lemma 46.11.16. In particular the functor $i_S^{-1} = \pi_{S,}$ is described by the rule $i_S^{-1}(\mathcal{G})(U/S) = \mathcal{G}(U/S)$.*

Proof. In this case the functor $u : S_{pro\text{-}\acute{e}tale} \rightarrow (Sch/S)_{pro\text{-}\acute{e}tale}$, in addition to the properties seen in the proof of Lemma 46.11.16 above, also is fully faithful and transforms the final object into the final object. The lemma follows from Sites, Lemma 7.20.8. \square

Definition 46.11.18. In the situation of Lemma 46.11.17 the functor $i_S^{-1} = \pi_{S,*}$ is often called the *restriction to the small pro-étale site*, and for a sheaf \mathcal{F} on the big pro-étale site we denote $\mathcal{F}|_{S_{pro\text{-}\acute{e}tale}}$ this restriction.

With this notation in place we have for a sheaf \mathcal{F} on the big site and a sheaf \mathcal{G} on the big site that

$$\begin{aligned} \text{Mor}_{Sh(S_{pro\text{-}\acute{e}tale})}(\mathcal{F}|_{S_{pro\text{-}\acute{e}tale}}, \mathcal{G}) &= \text{Mor}_{Sh((Sch/S)_{pro\text{-}\acute{e}tale})}(\mathcal{F}, i_{S,*}\mathcal{G}) \\ \text{Mor}_{Sh(S_{pro\text{-}\acute{e}tale})}(\mathcal{G}, \mathcal{F}|_{S_{pro\text{-}\acute{e}tale}}) &= \text{Mor}_{Sh((Sch/S)_{pro\text{-}\acute{e}tale})}(\pi_S^{-1}\mathcal{G}, \mathcal{F}) \end{aligned}$$

Moreover, we have $(i_{S,*}\mathcal{G})|_{S_{pro\text{-}\acute{e}tale}} = \mathcal{G}$ and we have $(\pi_S^{-1}\mathcal{G})|_{S_{pro\text{-}\acute{e}tale}} = \mathcal{G}$.

Lemma 46.11.19. *Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site. Let $f : T \rightarrow S$ be a morphism in $Sch_{pro\text{-}\acute{e}tale}$. The functor*

$$u : (Sch/T)_{pro\text{-}\acute{e}tale} \longrightarrow (Sch/S)_{pro\text{-}\acute{e}tale}, \quad V/T \longmapsto V/S$$

is cocontinuous, and has a continuous right adjoint

$$v : (Sch/S)_{pro\text{-}\acute{e}tale} \longrightarrow (Sch/T)_{pro\text{-}\acute{e}tale}, \quad (U \rightarrow S) \longmapsto (U \times_S T \rightarrow T).$$

They induce the same morphism of topoi

$$f_{big} : Sh((Sch/T)_{pro\text{-}\acute{e}tale}) \longrightarrow Sh((Sch/S)_{pro\text{-}\acute{e}tale})$$

We have $f_{big}^{-1}(\mathcal{G})(U/T) = \mathcal{G}(U/S)$. We have $f_{big,}(\mathcal{F})(U/S) = \mathcal{F}(U \times_S T/T)$. Also, f_{big}^{-1} has a left adjoint $f_{big}!$ which commutes with fibre products and equalizers.*

Proof. The functor u is cocontinuous, continuous, and commutes with fibre products and equalizers (details omitted; compare with proof of Lemma 46.11.16). Hence Sites, Lemmas 7.20.5 and 7.20.6 apply and we deduce the formula for f_{big}^{-1} and the existence of $f_{big}!$. Moreover, the functor v is a right adjoint because given U/T and V/S we have $\text{Mor}_S(u(U), V) = \text{Mor}_T(U, V \times_S T)$ as desired. Thus we may apply Sites, Lemmas 7.21.1 and 7.21.2 to get the formula for $f_{big,*}$. \square

Lemma 46.11.20. *Let $Sch_{pro\text{-}\acute{e}tale}$ be a big pro-étale site. Let $f : T \rightarrow S$ be a morphism in $Sch_{pro\text{-}\acute{e}tale}$.*

- (1) *We have $i_f = f_{big} \circ i_T$ with i_f as in Lemma 46.11.16 and i_T as in Lemma 46.11.17.*
- (2) *The functor $S_{pro\text{-}\acute{e}tale} \rightarrow T_{pro\text{-}\acute{e}tale}$, $(U \rightarrow S) \mapsto (U \times_S T \rightarrow T)$ is continuous and induces a morphism of topoi*

$$f_{small} : Sh(T_{pro\text{-}\acute{e}tale}) \longrightarrow Sh(S_{pro\text{-}\acute{e}tale}).$$

We have $f_{small,}(\mathcal{F})(U/S) = \mathcal{F}(U \times_S T/T)$.*

- (3) *We have a commutative diagram of morphisms of sites*

$$\begin{array}{ccc} T_{pro\text{-}\acute{e}tale} & \xleftarrow{\pi_T} & (Sch/T)_{pro\text{-}\acute{e}tale} \\ f_{small} \downarrow & & \downarrow f_{big} \\ S_{pro\text{-}\acute{e}tale} & \xleftarrow{\pi_S} & (Sch/S)_{pro\text{-}\acute{e}tale} \end{array}$$

so that $f_{small} \circ \pi_T = \pi_S \circ f_{big}$ as morphisms of topoi.

- (4) *We have $f_{small} = \pi_S \circ f_{big} \circ i_T = \pi_S \circ i_f$.*

Proof. The equality $i_f = f_{big} \circ i_T$ follows from the equality $i_f^{-1} = i_T^{-1} \circ f_{big}^{-1}$ which is clear from the descriptions of these functors above. Thus we see (1).

The functor $u : S_{pro\text{-}\acute{e}tale} \rightarrow T_{pro\text{-}\acute{e}tale}$, $u(U \rightarrow S) = (U \times_S T \rightarrow T)$ transforms coverings into coverings and commutes with fibre products, see Lemmas 46.11.4 and 46.11.14. Moreover, both $S_{pro\text{-}\acute{e}tale}$, $T_{pro\text{-}\acute{e}tale}$ have final objects, namely S/S

and T/T and $u(S/S) = T/T$. Hence by Sites, Proposition 7.15.6 the functor u corresponds to a morphism of sites $T_{pro\text{-}\acute{e}tale} \rightarrow S_{pro\text{-}\acute{e}tale}$. This in turn gives rise to the morphism of topoi, see Sites, Lemma 7.16.2. The description of the pushforward is clear from these references.

Part (3) follows because π_S and π_T are given by the inclusion functors and f_{small} and f_{big} by the base change functors $U \mapsto U \times_S T$.

Statement (4) follows from (3) by precomposing with i_T . □

In the situation of the lemma, using the terminology of Definition 46.11.18 we have: for \mathcal{F} a sheaf on the big pro-étale site of T

$$(f_{big,*}\mathcal{F})|_{S_{pro\text{-}\acute{e}tale}} = f_{small,*}(\mathcal{F}|_{T_{pro\text{-}\acute{e}tale}}),$$

This equality is clear from the commutativity of the diagram of sites of the lemma, since restriction to the small pro-étale site of T , resp. S is given by $\pi_{T,*}$, resp. $\pi_{S,*}$. A similar formula involving pullbacks and restrictions is false.

Lemma 46.11.21. *Given schemes X, Y, Z in $Sch_{pro\text{-}\acute{e}tale}$ and morphisms $f : X \rightarrow Y, g : Y \rightarrow Z$ we have $g_{big} \circ f_{big} = (g \circ f)_{big}$ and $g_{small} \circ f_{small} = (g \circ f)_{small}$.*

Proof. This follows from the simple description of pushforward and pullback for the functors on the big sites from Lemma 46.11.19. For the functors on the small sites this follows from the description of the pushforward functors in Lemma 46.11.20. □

We can think about a sheaf on the big pro-étale site of S as a collection of sheaves on the small pro-étale site on schemes over S .

Lemma 46.11.22. *Let S be a scheme contained in a big pro-étale site $Sch_{pro\text{-}\acute{e}tale}$. A sheaf \mathcal{F} on the big pro-étale site $(Sch/S)_{pro\text{-}\acute{e}tale}$ is given by the following data:*

- (1) for every $T/S \in \text{Ob}((Sch/S)_{pro\text{-}\acute{e}tale})$ a sheaf \mathcal{F}_T on $T_{pro\text{-}\acute{e}tale}$,
- (2) for every $f : T' \rightarrow T$ in $(Sch/S)_{pro\text{-}\acute{e}tale}$ a map $c_f : f_{small}^{-1}\mathcal{F}_T \rightarrow \mathcal{F}_{T'}$.

These data are subject to the following conditions:

- (i) given any $f : T' \rightarrow T$ and $g : T'' \rightarrow T'$ in $(Sch/S)_{pro\text{-}\acute{e}tale}$ the composition $g_{small}^{-1}c_f \circ c_g$ is equal to $c_{f \circ g}$, and
- (ii) if $f : T' \rightarrow T$ in $(Sch/S)_{pro\text{-}\acute{e}tale}$ is weakly étale then c_f is an isomorphism.

Proof. Identical to the proof of Topologies, Lemma 33.4.18. □

Lemma 46.11.23. *Let S be a scheme. Let $S_{affine,pro\text{-}\acute{e}tale}$ denote the full subcategory of $S_{pro\text{-}\acute{e}tale}$ consisting of affine objects. A covering of $S_{affine,pro\text{-}\acute{e}tale}$ will be a standard étale covering, see Definition 46.11.6. Then restriction*

$$\mathcal{F} \mapsto \mathcal{F}|_{S_{affine,\acute{e}tale}}$$

defines an equivalence of topoi $Sh(S_{pro\text{-}\acute{e}tale}) \cong Sh(S_{affine,pro\text{-}\acute{e}tale})$.

Proof. This you can show directly from the definitions, and is a good exercise. But it also follows immediately from Sites, Lemma 7.28.1 by checking that the inclusion functor $S_{affine,pro\text{-}\acute{e}tale} \rightarrow S_{pro\text{-}\acute{e}tale}$ is a special cocontinuous functor (see Sites, Definition 7.28.2). □

Lemma 46.11.24. *Let S be an affine scheme. Let S_{app} denote the full subcategory of $S_{pro\text{-}\acute{e}tale}$ consisting of affine objects U such that $\mathcal{O}(S) \rightarrow \mathcal{O}(U)$ is ind-étale. A covering of S_{app} will be a standard pro-étale covering, see Definition 46.11.6. Then restriction*

$$\mathcal{F} \longmapsto \mathcal{F}|_{S_{app}}$$

defines an equivalence of topoi $Sh(S_{pro\text{-}\acute{e}tale}) \cong Sh(S_{app})$.

Proof. By Lemma 46.11.23 we may replace $S_{pro\text{-}\acute{e}tale}$ by $S_{affine,pro\text{-}\acute{e}tale}$. The lemma follows from Sites, Lemma 7.28.1 by checking that the inclusion functor $S_{app} \rightarrow S_{affine,pro\text{-}\acute{e}tale}$ is a special cocontinuous functor, see Sites, Definition 7.28.2. The conditions of Sites, Lemma 7.28.1 follow immediately from the definition and the facts (a) any object U of $S_{affine,pro\text{-}\acute{e}tale}$ has a covering $\{V \rightarrow U\}$ with V ind-étale over X (Proposition 46.9.1) and (b) the functor u is fully faithful. \square

Next we show that cohomology of sheaves is independent of the choice of a partial universe. Namely, the functor g_* of the lemma below is an embedding of pro-étale topoi which does not change cohomology.

Lemma 46.11.25. *Let S be a scheme. Let $S_{pro\text{-}\acute{e}tale} \subset S'_{pro\text{-}\acute{e}tale}$ be two small pro-étale sites of S as constructed in Definition 46.11.12. Then the inclusion functor satisfies the assumptions of Sites, Lemma 7.20.8. Hence there exist morphisms of topoi*

$$Sh(S_{pro\text{-}\acute{e}tale}) \xrightarrow{g} Sh(S'_{pro\text{-}\acute{e}tale}) \xrightarrow{f} Sh(S_{pro\text{-}\acute{e}tale})$$

whose composition is isomorphic to the identity and with $f_ = g^{-1}$. Moreover,*

- (1) *for $\mathcal{F}' \in Ab(S'_{pro\text{-}\acute{e}tale})$ we have $H^p(S'_{pro\text{-}\acute{e}tale}, \mathcal{F}') = H^p(S_{pro\text{-}\acute{e}tale}, g^{-1}\mathcal{F}')$,*
- (2) *for $\mathcal{F} \in Ab(S_{pro\text{-}\acute{e}tale})$ we have*

$$H^p(S_{pro\text{-}\acute{e}tale}, \mathcal{F}) = H^p(S'_{pro\text{-}\acute{e}tale}, g_*\mathcal{F}) = H^p(S'_{pro\text{-}\acute{e}tale}, f^{-1}\mathcal{F}).$$

Proof. The inclusion functor is fully faithful and continuous. We have seen that $S_{pro\text{-}\acute{e}tale}$ and $S'_{pro\text{-}\acute{e}tale}$ have fibre products and final objects and that our functor commutes with these (Lemma 46.11.14). It follows from Lemma 46.11.11 that the inclusion functor is cocontinuous. Hence the existence of f and g follows from Sites, Lemma 7.20.8. The equality in (1) is Cohomology on Sites, Lemma 21.8.2. Part (2) follows from (1) as $\mathcal{F} = g^{-1}g_*\mathcal{F} = g^{-1}f^{-1}\mathcal{F}$. \square

Lemma 46.11.26. *Let S be a scheme. The topology on each of the pro-étale sites $S_{pro\text{-}\acute{e}tale}$, $(Sch/S)_{pro\text{-}\acute{e}tale}$, $S_{affine,pro\text{-}\acute{e}tale}$, and $(Aff/S)_{pro\text{-}\acute{e}tale}$ is subcanonical.*

Proof. Combine Lemma 46.11.2 and Descent, Lemma 34.9.3. \square

Lemma 46.11.27. *Let S be a scheme. The pro-étale sites $S_{pro\text{-}\acute{e}tale}$, $(Sch/S)_{pro\text{-}\acute{e}tale}$, $S_{affine,pro\text{-}\acute{e}tale}$, and $(Aff/S)_{pro\text{-}\acute{e}tale}$ and if S is affine S_{app} have enough quasi-compact, weakly contractible objects, see Sites, Definition 7.39.2.*

Proof. Follows immediately from Lemma 46.11.10. \square

46.12. Points of the pro-étale site

We first apply Deligne’s criterion to show that there are enough points.

Lemma 46.12.1. *Let S be a scheme. The pro-étale sites $S_{pro-étale}$, $(Sch/S)_{pro-étale}$, $S_{affine,pro-étale}$, and $(Aff/S)_{pro-étale}$ have enough points.*

Proof. The big topos is equivalent to the topos defined by $(Aff/S)_{pro-étale}$, see Lemma 46.11.15. The topos of sheaves on $S_{pro-étale}$ is equivalent to the topos associated to $S_{affine,pro-étale}$, see Lemma 46.11.23. The result for the sites $(Aff/S)_{pro-étale}$ and $S_{affine,pro-étale}$ follows immediately from Deligne’s result Sites, Proposition 7.38.3. \square

Let S be a scheme. Let $\bar{s} : \text{Spec}(k) \rightarrow S$ be a geometric point. We define a *pro-étale neighbourhood* of \bar{s} to be a commutative diagram

$$\begin{array}{ccc} \text{Spec}(k) & \xrightarrow{\bar{u}} & U \\ & \searrow \bar{s} & \downarrow \\ & & S \end{array}$$

with $U \rightarrow S$ weakly étale. In exactly the same manner as in the chapter on étale cohomology one shows that the category of pro-étale neighbourhoods of \bar{s} is cofiltered. Moreover, if (U, \bar{u}) is a pro-étale neighbourhood, and if $\{U_i \rightarrow U\}$ is a pro-étale covering, then there exists an i and a lift of \bar{u} to a geometric point \bar{u}_i of U_i . For \mathcal{F} in $Sh(S_{pro-étale})$ define the *stalk of \mathcal{F} at \bar{s}* by the formula

$$\mathcal{F}_{\bar{s}} = \text{colim}_{(U, \bar{u})} \mathcal{F}(U)$$

where the colimit is over all pro-étale neighbourhoods (U, \bar{u}) of \bar{s} with $U \in \text{Ob}(S_{pro-étale})$. A formal argument using the facts above shows the functor $\mathcal{F} \mapsto \mathcal{F}_{\bar{s}}$ defines a point of the topos $Sh(S_{pro-étale})$: it is an exact functor which commutes with arbitrary colimits. In fact, this functor has another description.

Lemma 46.12.2. *In the situation above the scheme $\text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh})$ is an object of $X_{pro-étale}$ and there is a canonical isomorphism*

$$\mathcal{F}(\text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh})) = \mathcal{F}_{\bar{s}}$$

functorial in \mathcal{F} .

Proof. The first statement is clear from the construction of the strict henselization as a filtered colimit of étale algebras over S , or by the characterization of weakly étale morphisms of More on Morphisms, Lemma 36.44.11. The second statement follows as by Olivier’s theorem (More on Algebra, Theorem 15.67.24) the scheme $\text{Spec}(\mathcal{O}_{S, \bar{s}}^{sh})$ is an initial object of the category of pro-étale neighbourhoods of \bar{s} . \square

Contrary to the situation with the étale topos of S it is not true that every point of $Sh(S_{pro-étale})$ is of this form, and it is not true that the collection of points associated to geometric point is conservative. Namely, suppose that $S = \text{Spec}(k)$ where k is an algebraically closed field. Let A be an abelian group. Consider the sheaf \mathcal{F} on $S_{pro-étale}$ defined by the rule

$$\mathcal{F}(U) = \frac{\{\text{functions } U \rightarrow A\}}{\{\text{locally constant functions}\}}$$

Then $\mathcal{F}(U) = 0$ if $U = S = \text{Spec}(k)$ but in general \mathcal{F} is not zero. Namely, $S_{\text{pro-étale}}$ contains objects with infinitely many points. For example, let $E = \lim E_n$ be an inverse limit of finite sets with surjective transition maps, e.g., $E = \lim \mathbf{Z}/n\mathbf{Z}$. The scheme $\text{Spec}(\text{colim Map}(E_n, k))$ is an object of $S_{\text{pro-étale}}$ because $\text{colim Map}(E_n, k)$ is weakly étale (even ind-Zariski) over k . Thus \mathcal{F} is a nonzero abelian sheaf whose stalk at the unique geometric point of S is zero.

The solution is to use the existence of quasi-compact, weakly contractible objects. First, there are enough quasi-compact, weakly contractible objects by Lemma 46.11.27. Second, if $W \in \text{Ob}(S_{\text{pro-étale}})$ is quasi-compact, weakly contractible, then the functor

$$\text{Sh}(S_{\text{pro-étale}}) \longrightarrow \text{Sets}, \quad \mathcal{F} \longmapsto \mathcal{F}(W)$$

is an exact functor $\text{Sh}(S_{\text{pro-étale}}) \rightarrow \text{Sets}$ which commutes with all limits. The functor

$$\text{Ab}(S_{\text{pro-étale}}) \longrightarrow \text{Ab}, \quad \mathcal{F} \longmapsto \mathcal{F}(W)$$

is exact and commutes with direct sums (as W is quasi-compact, see Sites, Lemma 7.11.2), hence commutes with all limits and colimits. Moreover, we can check exactness of a complex of abelian sheaves by evaluation at the quasi-compact, weakly contractible objects of $S_{\text{pro-étale}}$, see Cohomology on Sites, Proposition 21.38.2.

46.13. Compact generation

Let S be a scheme. The site $S_{\text{pro-étale}}$ has enough quasi-compact, weakly contractible objects U . For any sheaf of rings \mathcal{A} on $S_{\text{pro-étale}}$ the corresponding objects $j_{U!}\mathcal{A}_U$ are compact objects of the derived category $D(\mathcal{A})$, see Cohomology on Sites, Lemma 21.39.5. Since every complex of \mathcal{A} -modules is quasi-isomorphic to a complex whose terms are direct sums of the modules $j_{U!}\mathcal{A}_U$ (details omitted). Thus we see that $D(\mathcal{A})$ is generated by its compact objects.

The same argument works for the big pro-étale site of S .

46.14. Generalities on derived completion

We urge the reader to skip this section on a first reading.

The algebra version of this material can be found in More on Algebra, Section 15.64. Let \mathcal{O} be a sheaf of rings on a site \mathcal{C} . Let f be a global section of \mathcal{O} . We denote \mathcal{O}_f the sheaf associated to the presheaf of localizations $U \mapsto \mathcal{O}(U)_f$.

Lemma 46.14.1. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let f be a global section of \mathcal{O} .*

- (1) *For $L, N \in D(\mathcal{O}_f)$ we have $R\mathcal{H}om_{\mathcal{O}}(L, N) = R\mathcal{H}om_{\mathcal{O}_f}(L, N)$. In particular the two \mathcal{O}_f -structures on $R\mathcal{H}om_{\mathcal{O}}(L, N)$ agree.*
- (2) *For $K \in D(\mathcal{O})$ and $L \in D(\mathcal{O}_f)$ we have*

$$R\mathcal{H}om_{\mathcal{O}}(L, K) = R\mathcal{H}om_{\mathcal{O}_f}(L, R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K))$$

In particular $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K)) = R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K)$.

- (3) *If g is a second global section of \mathcal{O} , then*

$$R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_g, K)) = R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_{gf}, K).$$

Proof. Proof of (1). Let \mathcal{J}^\bullet be a K-injective complex of \mathcal{O}_f -modules representing N . By Cohomology on Sites, Lemma 21.20.3 it follows that \mathcal{J}^\bullet is a K-injective complex of \mathcal{O} -modules as well. Let \mathcal{F}^\bullet be a complex of \mathcal{O}_f -modules representing L . Then

$$R\mathcal{H}om_{\mathcal{O}}(L, N) = R\mathcal{H}om_{\mathcal{O}}(\mathcal{F}^\bullet, \mathcal{J}^\bullet) = R\mathcal{H}om_{\mathcal{O}_f}(\mathcal{F}^\bullet, \mathcal{J}^\bullet)$$

by Modules on Sites, Lemma 18.11.4 because \mathcal{J}^\bullet is a K-injective complex of \mathcal{O} and of \mathcal{O}_f -modules.

Proof of (2). Let \mathcal{I}^\bullet be a K-injective complex of \mathcal{O} -modules representing K . Then $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K)$ is represented by $\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, \mathcal{I}^\bullet)$ which is a K-injective complex of \mathcal{O}_f -modules and of \mathcal{O} -modules by Cohomology on Sites, Lemmas 21.20.4 and 21.20.3. Let \mathcal{F}^\bullet be a complex of \mathcal{O}_f -modules representing L . Then

$$R\mathcal{H}om_{\mathcal{O}}(L, K) = R\mathcal{H}om_{\mathcal{O}}(\mathcal{F}^\bullet, \mathcal{I}^\bullet) = R\mathcal{H}om_{\mathcal{O}_f}(\mathcal{F}^\bullet, \mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, \mathcal{I}^\bullet))$$

by Modules on Sites, Lemma 18.27.5 and because $\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, \mathcal{I}^\bullet)$ is a K-injective complex of \mathcal{O}_f -modules.

Proof of (3). This follows from the fact that $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_g, \mathcal{I}^\bullet)$ is K-injective as a complex of \mathcal{O} -modules and the fact that $\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, \mathcal{H}om_{\mathcal{O}}(\mathcal{O}_g, \mathcal{H})) = \mathcal{H}om_{\mathcal{O}}(\mathcal{O}_{gf}, \mathcal{H})$ for all sheaves of \mathcal{O} -modules \mathcal{H} . \square

Let $K \in D(\mathcal{O})$. We denote $T(K, f)$ a derived limit (Derived Categories, Definition 13.32.1) of the system

$$\dots \rightarrow K \xrightarrow{f} K \xrightarrow{f} K$$

in $D(\mathcal{O})$.

Lemma 46.14.2. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let f be a global section of \mathcal{O} . Let $K \in D(\mathcal{O})$. The following are equivalent*

- (1) $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K) = 0$,
- (2) $R\mathcal{H}om_{\mathcal{O}}(L, K) = 0$ for all L in $D(\mathcal{O}_f)$,
- (3) $T(K, f) = 0$.

Proof. It is clear that (2) implies (1). The implication (1) \Rightarrow (2) follows from Lemma 46.14.1. A free resolution of the \mathcal{O} -module \mathcal{O}_f is given by

$$0 \rightarrow \bigoplus_{n \in \mathbf{N}} \mathcal{O} \rightarrow \bigoplus_{n \in \mathbf{N}} \mathcal{O} \rightarrow \mathcal{O}_f \rightarrow 0$$

where the first map sends a local section (x_0, x_1, \dots) to $(fx_0 - x_1, fx_1 - x_2, \dots)$ and the second map sends (x_0, x_1, \dots) to $x_0 + x_1/f + x_2/f^2 + \dots$. Applying $\mathcal{H}om_{\mathcal{O}}(-, \mathcal{I}^\bullet)$ where \mathcal{I}^\bullet is a K-injective complex of \mathcal{O} -modules representing K we get a short exact sequence of complexes

$$0 \rightarrow \mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, \mathcal{I}^\bullet) \rightarrow \prod \mathcal{I}^\bullet \rightarrow \prod \mathcal{I}^\bullet \rightarrow 0$$

because \mathcal{I}^n is an injective \mathcal{O} -module. The products are products in $D(\mathcal{O})$, see Injectives, Lemma 19.13.4. This means that the object $T(K, f)$ is a representative of $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K)$ in $D(\mathcal{O})$. Thus the equivalence of (1) and (3). \square

Lemma 46.14.3. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $K \in D(\mathcal{O})$. The rule which associates to U the set $\mathcal{I}(U)$ of sections $f \in \mathcal{O}(U)$ such that $T(K|_U, f) = 0$ is a sheaf of ideals in \mathcal{O} .*

Proof. We will use the results of Lemma 46.14.2 without further mention. If $f \in \mathcal{I}(U)$, and $g \in \mathcal{O}(U)$, then $\mathcal{O}_{U,gf}$ is an $\mathcal{O}_{U,f}$ -module hence $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_{U,gf}, K|_U) = 0$, hence $gf \in \mathcal{I}(U)$. Suppose $f, g \in \mathcal{O}(U)$. Then there is a short exact sequence

$$0 \rightarrow \mathcal{O}_{U,f+g} \rightarrow \mathcal{O}_{U,f(f+g)} \oplus \mathcal{O}_{U,g(f+g)} \rightarrow \mathcal{O}_{U,gf(f+g)} \rightarrow 0$$

because f, g generate the unit ideal in $\mathcal{O}(U)_{f+g}$. This follows from Algebra, Lemma 10.22.1 and the easy fact that the last arrow is surjective. Because $R\mathcal{H}om_{\mathcal{O}}(-, K|_U)$ is an exact functor of triangulated categories the vanishing of $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,f(f+g)}, K|_U)$, $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,g(f+g)}, K|_U)$, and $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,gf(f+g)}, K|_U)$, implies the vanishing of $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,f+g}, K|_U)$. We omit the verification of the sheaf condition. \square

We can make the following definition for any ringed site.

Definition 46.14.4. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $\mathcal{I} \subset \mathcal{O}$ be a sheaf of ideals. Let $K \in D(\mathcal{O})$. We say that K is *derived complete with respect to \mathcal{I}* if for every object U of \mathcal{C} and $f \in \mathcal{I}(U)$ the object $T(K|_U, f)$ of $D(\mathcal{O}_U)$ is zero.

It is clear that the full subcategory $D_{comp}(\mathcal{O}) = D_{comp}(\mathcal{O}, \mathcal{I}) \subset D(\mathcal{O})$ consisting of derived complete objects is a saturated triangulated subcategory, see Derived Categories, Definitions 13.3.4 and 13.6.1. This subcategory is preserved under products and homotopy limits in $D(\mathcal{O})$. But it is not preserved under countable direct sums in general.

Lemma 46.14.5. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $\mathcal{I} \subset \mathcal{O}$ be a sheaf of ideals. If $K \in D(\mathcal{O})$ and $L \in D_{comp}(\mathcal{O})$, then $R\mathcal{H}om_{\mathcal{O}}(K, L) \in D_{comp}(\mathcal{O})$.*

Proof. Let U be an object of \mathcal{C} and let $f \in \mathcal{I}(U)$. Recall that

$$\mathrm{Hom}_{D(\mathcal{O}_U)}(\mathcal{O}_{U,f}, R\mathcal{H}om_{\mathcal{O}}(K, L)|_U) = \mathrm{Hom}_{D(\mathcal{O}_U)}(K|_U \otimes_{\mathcal{O}_U}^{\mathbf{L}} \mathcal{O}_{U,f}, L|_U)$$

by Cohomology on Sites, Lemma 21.26.2. The right hand side is zero by Lemma 46.14.2 and the relationship between internal hom and actual hom, see Cohomology on Sites, Lemma 21.26.1. The same vanishing holds for all U'/U . Thus the object $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,f}, R\mathcal{H}om_{\mathcal{O}}(K, L)|_U)$ of $D(\mathcal{O}_U)$ has vanishing 0th cohomology sheaf (by locus citatus). Similarly for the other cohomology sheaves, i.e., $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,f}, R\mathcal{H}om_{\mathcal{O}}(K, L)|_U)$ is zero in $D(\mathcal{O}_U)$. By Lemma 46.14.2 we conclude. \square

Lemma 46.14.6. *Let \mathcal{C} be a site. Let $\mathcal{O} \rightarrow \mathcal{O}'$ be a homomorphism of sheaves of rings. Let $\mathcal{I} \subset \mathcal{O}$ be a sheaf of ideals. The inverse image of $D_{comp}(\mathcal{O}, \mathcal{I})$ under the restriction functor $D(\mathcal{O}') \rightarrow D(\mathcal{O})$ is $D_{comp}(\mathcal{O}', \mathcal{I}\mathcal{O}')$.*

Proof. Using Lemma 46.14.3 we see that $K' \in D(\mathcal{O}')$ is in $D_{comp}(\mathcal{O}', \mathcal{I}\mathcal{O}')$ if and only if $T(K'|_U, f)$ is zero for every local section $f \in \mathcal{I}(U)$. Observe that the cohomology sheaves of $T(K'|_U, f)$ are computed in the category of abelian sheaves, so it doesn't matter whether we think of f as a section of \mathcal{O} or take the image of f as a section of \mathcal{O}' . The lemma follows immediately from this and the definition of derived complete objects. \square

Lemma 46.14.7. *Let $f : (Sh(\mathcal{D}), \mathcal{O}') \rightarrow (Sh(\mathcal{C}), \mathcal{O})$ be a morphism of ringed topoi. Let $\mathcal{I} \subset \mathcal{O}$ and $\mathcal{I}' \subset \mathcal{O}'$ be sheaves of ideals such that $f^\#$ sends $f^{-1}\mathcal{I}$ into \mathcal{I}' . Then Rf_* sends $D_{comp}(\mathcal{O}', \mathcal{I}')$ into $D_{comp}(\mathcal{O}, \mathcal{I})$.*

Proof. We may assume f is given by a morphism of ringed sites corresponding to a continuous functor $\mathcal{C} \rightarrow \mathcal{D}$ (Modules on Sites, Lemma 18.7.2). Let U be an object of \mathcal{C} and let g be a section of \mathcal{I} over U . We have to show that $\text{Hom}_{D(\mathcal{O}_U)}(\mathcal{O}_{U,g}, Rf_*K|_U) = 0$ whenever K is derived complete with respect to \mathcal{I}' . Namely, by Cohomology on Sites, Lemma 21.26.1 this, applied to all objects over U and all shifts of K , will imply that $R\mathcal{H}om_{\mathcal{O}_U}(\mathcal{O}_{U,g}, Rf_*K|_U)$ is zero, which implies that $T(Rf_*K|_U, g)$ is zero (Lemma 46.14.2) which is what we have to show (Definition 46.14.4). Let V in \mathcal{D} be the image of U . Then

$$\text{Hom}_{D(\mathcal{O}_U)}(\mathcal{O}_{U,g}, Rf_*K|_U) = \text{Hom}_{D(\mathcal{O}'_V)}(\mathcal{O}'_{V,g'}, K|_V) = 0$$

where $g' = f^\sharp(g) \in \mathcal{I}'(V)$. The second equality because K is derived complete and the first equality because the derived pullback of $\mathcal{O}_{U,g}$ is $\mathcal{O}'_{V,g'}$ and Cohomology on Sites, Lemma 21.19.1. \square

The following lemma is the simplest case where one has derived completion.

Lemma 46.14.8. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed on a site. Let f_1, \dots, f_r be global sections of \mathcal{O} . Let $\mathcal{I} \subset \mathcal{O}$ be the ideal sheaf generated by f_1, \dots, f_r . Then the inclusion functor $D_{\text{comp}}(\mathcal{O}) \rightarrow D(\mathcal{O})$ has a left adjoint, i.e., given any object K of $D(\mathcal{O})$ there exists a map $K \rightarrow K^\wedge$ with K^\wedge in $D_{\text{comp}}(\mathcal{O})$ such that the map*

$$\text{Hom}_{D(\mathcal{O})}(K^\wedge, E) \longrightarrow \text{Hom}_{D(\mathcal{O})}(K, E)$$

is bijective whenever E is in $D_{\text{comp}}(\mathcal{O})$. In fact we have

$$K^\wedge = R\mathcal{H}om_{\mathcal{O}}(\mathcal{O} \rightarrow \prod_{i_0} \mathcal{O}_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} \mathcal{O}_{f_{i_0}f_{i_1}} \rightarrow \dots \rightarrow \mathcal{O}_{f_1 \dots f_r}, K)$$

functorially in K .

Proof. Define K^\wedge by the last displayed formula of the lemma. There is a map of complexes

$$(\mathcal{O} \rightarrow \prod_{i_0} \mathcal{O}_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} \mathcal{O}_{f_{i_0}f_{i_1}} \rightarrow \dots \rightarrow \mathcal{O}_{f_1 \dots f_r}) \longrightarrow \mathcal{O}$$

which induces a map $K \rightarrow K^\wedge$. It suffices to prove that K^\wedge is derived complete and that $K \rightarrow K^\wedge$ is an isomorphism if K is derived complete.

Let f be a global section of \mathcal{O} . By Lemma 46.14.1 the object $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K^\wedge)$ is equal to

$$R\mathcal{H}om_{\mathcal{O}}((\mathcal{O}_f \rightarrow \prod_{i_0} \mathcal{O}_{ff_{i_0}} \rightarrow \prod_{i_0 < i_1} \mathcal{O}_{ff_{i_0}f_{i_1}} \rightarrow \dots \rightarrow \mathcal{O}_{ff_1 \dots f_r}), K)$$

If $f = f_i$ for some i , then f_1, \dots, f_r generate the unit ideal in \mathcal{O}_f , hence the extended alternating Čech complex

$$\mathcal{O}_f \rightarrow \prod_{i_0} \mathcal{O}_{ff_{i_0}} \rightarrow \prod_{i_0 < i_1} \mathcal{O}_{ff_{i_0}f_{i_1}} \rightarrow \dots \rightarrow \mathcal{O}_{ff_1 \dots f_r}$$

is zero (even homotopic to zero). In this way we see that K^\wedge is derived complete.

If K is derived complete, then $R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}_f, K)$ is zero for all $f = f_{i_0} \dots f_{i_p}$, $p \geq 0$. Thus $K \rightarrow K^\wedge$ is an isomorphism in $D(\mathcal{O})$. \square

Next we explain why derived completion is a completion.

Lemma 46.14.9. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed on a site. Let f_1, \dots, f_r be global sections of \mathcal{O} . Let $\mathcal{I} \subset \mathcal{O}$ be the ideal sheaf generated by f_1, \dots, f_r . Let $K \in D(\mathcal{O})$. The derived completion K^\wedge of Lemma 46.14.8 is given by the formula*

$$K^\wedge = R \lim K \otimes_{\mathcal{O}}^{\mathbf{L}} K_n$$

where $K_n = K(\mathcal{O}, f_1^n, \dots, f_r^n)$ is the Koszul complex on f_1^n, \dots, f_r^n over \mathcal{O} .

Proof. In More on Algebra, Lemma 15.20.13 we have seen that the extended alternating Čech complex

$$\mathcal{O} \rightarrow \prod_{i_0} \mathcal{O}_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} \mathcal{O}_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow \mathcal{O}_{f_1 \dots f_r}$$

is a colimit of the Koszul complexes $K^n = K(\mathcal{O}, f_1^n, \dots, f_r^n)$ sitting in degrees $0, \dots, r$. Note that K^n is a finite chain complex of finite free \mathcal{O} -modules with dual $\mathcal{H}om_{\mathcal{O}}(K^n, \mathcal{O}) = K_n$ where K_n is the Koszul cochain complex sitting in degrees $-r, \dots, 0$ (as usual). By Lemma 46.14.8 the functor $K \mapsto K^\wedge$ is gotten by taking $R\mathcal{H}om$ from the extended alternating Čech complex into K :

$$K^\wedge = R\mathcal{H}om(\text{colim } K^n, K)$$

This is equal to $R \lim(K \otimes_{\mathcal{O}}^{\mathbf{L}} K_n)$ by Cohomology on Sites, Lemma 21.36.10. \square

Lemma 46.14.10. *There exist a way to construct*

- (1) *for every pair (A, I) consisting of a ring A and a finitely generated ideal $I \subset A$ a complex $K(A, I)$ of A -modules,*
- (2) *a map $K(A, I) \rightarrow A$ of complexes of A -modules,*
- (3) *for every ring map $A \rightarrow B$ and finitely generated ideal $I \subset A$ a map of complexes $K(A, I) \rightarrow K(B, IB)$,*

such that

- (a) *for $A \rightarrow B$ and $I \subset A$ finitely generated the diagram*

$$\begin{array}{ccc} K(A, I) & \longrightarrow & A \\ \downarrow & & \downarrow \\ K(B, IB) & \longrightarrow & B \end{array}$$

commutes,

- (b) *for $A \rightarrow B \rightarrow C$ and $I \subset A$ finitely generated the composition of the maps $K(A, I) \rightarrow K(B, IB) \rightarrow K(C, IC)$ is the map $K(A, I) \rightarrow K(C, IC)$.*
- (c) *for $A \rightarrow B$ and a finitely generated ideal $I \subset A$ the induced map $K(A, I) \otimes_A^{\mathbf{L}} B \rightarrow K(B, IB)$ is an isomorphism in $D(B)$, and*
- (d) *if $I = (f_1, \dots, f_r) \subset A$ then there is a commutative diagram*

$$\begin{array}{ccc} (A \rightarrow \prod_{i_0} A_{f_{i_0}} \rightarrow \prod_{i_0 < i_1} A_{f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow A_{f_1 \dots f_r}) & \longrightarrow & K(A, I) \\ \downarrow & & \downarrow \\ A & \xrightarrow{1} & A \end{array}$$

in $D(A)$ whose horizontal arrows are isomorphisms.

Proof. Let S be the set of rings A_0 of the form $A_0 = \mathbf{Z}[x_1, \dots, x_n]/J$. Every finite type \mathbf{Z} -algebra is isomorphic to an element of S . Let \mathcal{A}_0 be the category whose objects are pairs (A_0, I_0) where $A_0 \in S$ and $I_0 \subset A_0$ is an ideal and whose morphisms $(A_0, I_0) \rightarrow (B_0, J_0)$ are ring maps $\varphi : A_0 \rightarrow B_0$ such that $J_0 = \varphi(I_0)B_0$.

Suppose we can construct $K(A_0, I_0) \rightarrow A_0$ functorially for objects of \mathcal{A}_0 having properties (a), (b), (c), and (d). Then we take

$$K(A, I) = \operatorname{colim}_{\varphi: (A_0, I_0) \rightarrow (A, I)} K(A_0, I_0)$$

where the colimit is over ring maps $\varphi : A_0 \rightarrow A$ such that $\varphi(I_0)A = I$ with (A_0, I_0) in \mathcal{A}_0 . A morphism between $(A_0, I_0) \rightarrow (A, I)$ and $(A'_0, I'_0) \rightarrow (A, I)$ are given by maps $(A_0, I_0) \rightarrow (A'_0, I'_0)$ in \mathcal{A}_0 commuting with maps to A . The category of these $(A_0, I_0) \rightarrow (A, I)$ is filtered (details omitted). Moreover, $\operatorname{colim}_{\varphi: (A_0, I_0) \rightarrow (A, I)} A_0 = A$ so that $K(A, I)$ is a complex of A -modules. Finally, given $\varphi : A \rightarrow B$ and $I \subset A$ for every $(A_0, I_0) \rightarrow (A, I)$ in the colimit, the composition $(A_0, I_0) \rightarrow (B, IB)$ lives in the colimit for (B, IB) . In this way we get a map on colimits. Properties (a), (b), (c), and (d) follow readily from this and the corresponding properties of the complexes $K(A_0, I_0)$.

Endow $\mathcal{C}_0 = \mathcal{A}_0^{opp}$ with the chaotic topology. We equip \mathcal{C}_0 with the sheaf of rings $\mathcal{O} : (A, I) \mapsto A$. The ideals I fit together to give a sheaf of ideals $\mathcal{I} \subset \mathcal{O}$. Choose an injective resolution $\mathcal{O} \rightarrow \mathcal{J}^\bullet$. Consider the object

$$\mathcal{F}^\bullet = \bigcup_n \mathcal{J}^\bullet[\mathcal{I}^n]$$

Let $U = (A, I) \in \operatorname{Ob}(\mathcal{C}_0)$. Since the topology in \mathcal{C}_0 is chaotic, the value $\mathcal{J}^\bullet(U)$ is a resolution of A by injective A -modules. Hence the value $\mathcal{F}^\bullet(U)$ is an object of $D(A)$ representing the image of $R\Gamma_I(A)$ in $D(A)$, see Dualizing Complexes, Section 43.8. Choose a complex of \mathcal{O} -modules \mathcal{K}^\bullet and a commutative diagram

$$\begin{array}{ccc} \mathcal{O} & \longrightarrow & \mathcal{J}^\bullet \\ \uparrow & & \uparrow \\ \mathcal{K}^\bullet & \longrightarrow & \mathcal{F}^\bullet \end{array}$$

where the horizontal arrows are quasi-isomorphisms. This is possible by the construction of the derived category $D(\mathcal{O})$. Set $K(A, I) = \mathcal{K}^\bullet(U)$ where $U = (A, I)$. Properties (a) and (b) are clear and properties (c) and (d) follow from Dualizing Complexes, Lemmas 43.8.10 and 43.8.12. \square

Lemma 46.14.11. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $\mathcal{I} \subset \mathcal{O}$ be a finite type sheaf of ideals. There exists a map $K \rightarrow \mathcal{O}$ in $D(\mathcal{O})$ such that for every $U \in \operatorname{Ob}(\mathcal{C})$ such that $\mathcal{I}|_U$ is generated by $f_1, \dots, f_r \in \mathcal{I}(U)$ there is an isomorphism*

$$(\mathcal{O}_U \rightarrow \prod_{i_0} \mathcal{O}_{U, f_{i_0}} \rightarrow \prod_{i_0 < i_1} \mathcal{O}_{U, f_{i_0} f_{i_1}} \rightarrow \dots \rightarrow \mathcal{O}_{U, f_1 \dots f_r}) \longrightarrow K|_U$$

compatible with maps to \mathcal{O}_U .

Proof. Let $\mathcal{C}' \subset \mathcal{C}$ be the full subcategory of objects U such that $\mathcal{I}|_U$ is generated by finitely many sections. Then $\mathcal{C}' \rightarrow \mathcal{C}$ is a special cocontinuous functor (Sites, Definition 7.28.2). Hence it suffices to work with \mathcal{C}' , see Sites, Lemma 7.28.1. In other words we may assume that for every object U of \mathcal{C} there exists a finitely generated ideal $I \subset \mathcal{I}(U)$ such that $\mathcal{I}|_U = \operatorname{Im}(I \otimes \mathcal{O}_U \rightarrow \mathcal{O}_U)$. We will say that I generates $\mathcal{I}|_U$. Warning: We do not know that $\mathcal{I}(U)$ is a finitely generated ideal in $\mathcal{O}(U)$.

Let U be an object and $I \subset \mathcal{O}(U)$ a finitely generated ideal which generates $\mathcal{I}|_U$. On the category \mathcal{C}/U consider the complex of presheaves

$$K_{U, I}^\bullet : U'/U \mapsto K(\mathcal{O}(U'), I\mathcal{O}(U'))$$

with $K(-, -)$ as in Lemma 46.14.10. We claim that the sheafification of this is independent of the choice of I . Indeed, if $I' \subset \mathcal{O}(U)$ is a finitely generated ideal which also generates $\mathcal{I}|_U$, then there exists a covering $\{U_j \rightarrow U\}$ such that $I\mathcal{O}(U_j) = I'\mathcal{O}(U_j)$. (Hint: this works because both I and I' are finitely generated and generate $\mathcal{I}|_U$.) Hence $K_{U,I}^\bullet$ and $K_{U,I'}^\bullet$ are the *same* for any object lying over one of the U_j . The statement on sheafifications follows. Denote $K_{\mathcal{U}}^\bullet$ the common value.

The independence of choice of I also shows that $K_{U|_{\mathcal{C}/U'}}^\bullet = K_{U'}^\bullet$, whenever we are given a morphism $U' \rightarrow U$ and hence a localization morphism $\mathcal{C}/U' \rightarrow \mathcal{C}/U$. Thus the complexes $K_{\mathcal{U}}^\bullet$ glue to give a single well defined complex K^\bullet of \mathcal{O} -modules. The existence of the map $K^\bullet \rightarrow \mathcal{O}$ and the quasi-isomorphism of the lemma follow immediately from the corresponding properties of the complexes $K(-, -)$ in Lemma 46.14.10. \square

Proposition 46.14.12. *Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $\mathcal{I} \subset \mathcal{O}$ be a finite type sheaf of ideals. There exists a left adjoint to the inclusion functor $D_{\text{comp}}(\mathcal{O}) \rightarrow D(\mathcal{O})$.*

Proof. Let $K \rightarrow \mathcal{O}$ in $D(\mathcal{O})$ be as constructed in Lemma 46.14.11. Let $E \in D(\mathcal{O})$. Then $E^\wedge = R\mathcal{H}om(K, E)$ together with the map $E \rightarrow E^\wedge$ will do the job. Namely, locally on the site \mathcal{C} we recover the adjoint of Lemma 46.14.8. This shows that E^\wedge is always derived complete and that $E \rightarrow E^\wedge$ is an isomorphism if E is derived complete. \square

Remark 46.14.13 (Localization and derived completion). Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $\mathcal{I} \subset \mathcal{O}$ be a finite type sheaf of ideals. Let $K \mapsto K^\wedge$ be the derived completion functor of Proposition 46.14.12. It follows from the construction in the proof of the proposition that $K^\wedge|_U$ is the derived completion of $K|_U$ for any $U \in \text{Ob}(\mathcal{C})$. But we can also prove this as follows. From the definition of derived complete objects it follows that $K^\wedge|_U$ is derived complete. Thus we obtain a canonical map $a : (K|_U)^\wedge \rightarrow K^\wedge|_U$. On the other hand, if E is a derived complete object of $D(\mathcal{O}_U)$, then Rj_*E is a derived complete object of $D(\mathcal{O})$ by Lemma 46.14.7. Here j is the localization morphism (Modules on Sites, Section 18.19). Hence we also obtain a canonical map $b : K^\wedge \rightarrow Rj_*((K|_U)^\wedge)$. We omit the (formal) verification that the adjoint of b is the inverse of a .

Remark 46.14.14 (Completed tensor product). Let $(\mathcal{C}, \mathcal{O})$ be a ringed site. Let $\mathcal{I} \subset \mathcal{O}$ be a finite type sheaf of ideals. Denote $K \mapsto K^\wedge$ the adjoint of Proposition 46.14.12. Then we set

$$K \otimes_{\mathcal{O}}^\wedge L = (K \otimes_{\mathcal{O}}^{\mathbf{L}} L)^\wedge$$

This *completed tensor product* defines a functor $D_{\text{comp}}(\mathcal{O}) \times D_{\text{comp}}(\mathcal{O}) \rightarrow D_{\text{comp}}(\mathcal{O})$ such that we have

$$\text{Hom}_{D_{\text{comp}}(\mathcal{O})}(K, R\mathcal{H}om_{\mathcal{O}}(L, M)) = \text{Hom}_{D_{\text{comp}}(\mathcal{O})}(K \otimes_{\mathcal{O}}^\wedge L, M)$$

for $K, L, M \in D_{\text{comp}}(\mathcal{O})$. Note that $R\mathcal{H}om_{\mathcal{O}}(L, M) \in D_{\text{comp}}(\mathcal{O})$ by Lemma 46.14.5.

Lemma 46.14.15. *Let \mathcal{C} be a site. Assume $\varphi : \mathcal{O} \rightarrow \mathcal{O}'$ is a flat homomorphism of sheaves of rings. Let f_1, \dots, f_r be global sections of \mathcal{O} such that $\mathcal{O}/(f_1, \dots, f_r) \cong$*

$\mathcal{O}'/(f_1, \dots, f_r)$. Then the map of extended alternating Čech complexes

$$\begin{array}{ccccccc} \mathcal{O} & \rightarrow & \prod_{i_0} \mathcal{O}_{f_{i_0}} & \rightarrow & \prod_{i_0 < i_1} \mathcal{O}_{f_{i_0} f_{i_1}} & \rightarrow & \dots \rightarrow \mathcal{O}_{f_1 \dots f_r} \\ & & & & \downarrow & & \\ \mathcal{O}' & \rightarrow & \prod_{i_0} \mathcal{O}'_{f_{i_0}} & \rightarrow & \prod_{i_0 < i_1} \mathcal{O}'_{f_{i_0} f_{i_1}} & \rightarrow & \dots \rightarrow \mathcal{O}'_{f_1 \dots f_r} \end{array}$$

is a quasi-isomorphism.

Proof. Observe that the second complex is the tensor product of the first complex with \mathcal{O}' . We can write the first extended alternating Čech complex as a colimit of the Koszul complexes $K_n = K(\mathcal{O}, f_1^n, \dots, f_r^n)$, see More on Algebra, Lemma 15.20.13. Hence it suffices to prove $K_n \rightarrow K_n \otimes_{\mathcal{O}} \mathcal{O}'$ is a quasi-isomorphism. Since $\mathcal{O} \rightarrow \mathcal{O}'$ is flat it suffices to show that $H^i \rightarrow H^i \otimes_{\mathcal{O}} \mathcal{O}'$ is an isomorphism where H^i is the i th cohomology sheaf $H^i = H^i(K_n)$. These sheaves are annihilated by f_1^n, \dots, f_r^n , see More on Algebra, Lemma 15.20.6. Thus it suffices to show that $\mathcal{O}/(f_1^n, \dots, f_r^n) \rightarrow \mathcal{O}'/(f_1^n, \dots, f_r^n)$ is an isomorphism. Equivalently, we will show that $\mathcal{O}/(f_1, \dots, f_r)^n \rightarrow \mathcal{O}'/(f_1, \dots, f_r)^n$ is an isomorphism for all n . This holds for $n = 1$ by assumption. It follows for all n by induction using Modules on Sites, Lemma 18.28.13 applied to the ring map $\mathcal{O}/(f_1, \dots, f_r)^{n+1} \rightarrow \mathcal{O}/(f_1, \dots, f_r)^n$ and the module $\mathcal{O}'/(f_1, \dots, f_r)^{n+1}$. \square

Lemma 46.14.16. *Let \mathcal{C} be a site with enough points. Let $\mathcal{O} \rightarrow \mathcal{O}'$ be a homomorphism of sheaves of rings. Let $\mathcal{I} \subset \mathcal{O}$ be a finite type sheaf of ideals. If $\mathcal{O} \rightarrow \mathcal{O}'$ is flat and $\mathcal{O}/\mathcal{I} \cong \mathcal{O}'/\mathcal{I}\mathcal{O}'$, then the restriction functor $D(\mathcal{O}') \rightarrow D(\mathcal{O})$ induces an equivalence $D_{\text{comp}}(\mathcal{O}', \mathcal{I}\mathcal{O}') \rightarrow D_{\text{comp}}(\mathcal{O}, \mathcal{I})$.*

Proof. Let $K \rightarrow \mathcal{O}$ be the morphism of $D(\mathcal{O})$ constructed in Lemma 46.14.11. Set $K' = K \otimes_{\mathcal{O}} \mathcal{O}'$. Then $K' \rightarrow \mathcal{O}'$ is a map in $D(\mathcal{O}')$ satisfying the same condition with respect to $\mathcal{I}' = \mathcal{I}\mathcal{O}'$. The map $K \rightarrow K'$ is a quasi-isomorphism by Lemma 46.14.15. Now, let $E \in D_{\text{comp}}(\mathcal{O}, \mathcal{I})$. By the proof of Proposition 46.14.12 we have the first equality in

$$E = R\mathcal{H}om_{\mathcal{O}}(K, E) = R\mathcal{H}om_{\mathcal{O}}(K', E)$$

Since K' is a complex of \mathcal{O}' modules, this shows that E is the image of some $E' \in D(\mathcal{O}')$. By Lemma 46.14.6 we have $E' \in D_{\text{comp}}(\mathcal{O}')$. Thus the functor is essentially surjective. In fact the functor $E \mapsto R\mathcal{H}om_{\mathcal{O}}(K', E)$ is a quasi-inverse to the restriction functor. The formula above shows this in one direction. The other direction hinges on the fact that for $E' \in D_{\text{comp}}(\mathcal{O}')$ the map

$$R\mathcal{H}om_{\mathcal{O}}(K', E') \rightarrow R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}', E')$$

is an isomorphism in $D(\mathcal{O}')$ for both \mathcal{O}' -module structures and the existence of a map $E' \rightarrow R\mathcal{H}om_{\mathcal{O}}(\mathcal{O}', E')$ which is \mathcal{O}' -linear for both \mathcal{O}' -module structures on the target. Details omitted. \square

Lemma 46.14.17. *Let $f : (\text{Sh}(\mathcal{D}), \mathcal{O}') \rightarrow (\text{Sh}(\mathcal{C}), \mathcal{O})$ be a morphism of ringed topoi. Let $\mathcal{I} \subset \mathcal{O}$ and $\mathcal{I}' \subset \mathcal{O}'$ be finite type sheaves of ideals such that $f^\#$ sends $f^{-1}\mathcal{I}$ into \mathcal{I}' . Then Rf_* sends $D_{\text{comp}}(\mathcal{O}', \mathcal{I}')$ into $D_{\text{comp}}(\mathcal{O}, \mathcal{I})$ and has a left adjoint Lf_{comp}^* which is Lf^* followed by derived completion.*

Proof. The first statement we have seen in Lemma 46.14.7. Note that the second statement makes sense as we have a derived completion functor $D(\mathcal{O}') \rightarrow D_{comp}(\mathcal{O}', \mathcal{I}')$ by Proposition 46.14.12. OK, so now let $K \in D_{comp}(\mathcal{O}, \mathcal{I})$ and $M \in D_{comp}(\mathcal{O}', \mathcal{I}')$. Then we have

$$R\mathrm{Hom}(K, Rf_*M) = R\mathrm{Hom}(Lf^*K, M) = R\mathrm{Hom}(Lf_{comp}^*K, M)$$

by the universal property of derived completion. □

Lemma 46.14.18. *Let $f : (Sh(\mathcal{D}), \mathcal{O}') \rightarrow (Sh(\mathcal{C}), \mathcal{O})$ be a morphism of ringed topoi. Let $\mathcal{I} \subset \mathcal{O}$ be a finite type sheaf of ideals. Let $\mathcal{I}' \subset \mathcal{O}'$ be the ideal generated by $f^\sharp(f^{-1}\mathcal{I})$. Then Rf_* commutes with derived completion, i.e., $Rf_*(K^\wedge) = (Rf_*K)^\wedge$.*

Proof. By Proposition 46.14.12 the derived completion functors exist. By Lemma 46.14.7 the object $Rf_*(K^\wedge)$ is derived complete, and hence we obtain a canonical map $(Rf_*K)^\wedge \rightarrow Rf_*(K^\wedge)$ by the universal property of derived completion. We may check this map is an isomorphism locally on \mathcal{C} . Thus, since derived completion commutes with localization (Remark 46.14.13) we may assume that \mathcal{I} is generated by global sections f_1, \dots, f_r . Then \mathcal{I}' is generated by $g_i = f^\sharp(f_i)$. By Lemma 46.14.9 we have to prove that

$$R\mathrm{lim} (Rf_*K \otimes_{\mathcal{O}}^{\mathbf{L}} K(\mathcal{O}, f_1^n, \dots, f_r^n)) = Rf_* (R\mathrm{lim} K \otimes_{\mathcal{O}'}^{\mathbf{L}} K(\mathcal{O}', g_1^n, \dots, g_r^n))$$

Because Rf_* commutes with $R\mathrm{lim}$ (Cohomology on Sites, Lemma 21.21.2) it suffices to prove that

$$Rf_*K \otimes_{\mathcal{O}}^{\mathbf{L}} K(\mathcal{O}, f_1^n, \dots, f_r^n) = Rf_* (K \otimes_{\mathcal{O}'}^{\mathbf{L}} K(\mathcal{O}', g_1^n, \dots, g_r^n))$$

This follows from the projection formula (Cohomology on Sites, Lemma 21.37.1) and the fact that $Lf^*K(\mathcal{O}, f_1^n, \dots, f_r^n) = K(\mathcal{O}', g_1^n, \dots, g_r^n)$. □

46.15. Application to theorem on formal functions

We interrupt the flow of the exposition to talk a little bit about derived completion in the setting of quasi-coherent modules on schemes and to use this to give a somewhat different proof of the theorem on formal functions. We give some pointers to the literature in Remark 46.15.5.

Lemma 46.14.18 is a (very formal) derived version of the theorem on formal functions (Cohomology of Schemes, Theorem 29.18.5). To make this more explicit, suppose $f : X \rightarrow S$ is a morphism of schemes, $\mathcal{I} \subset \mathcal{O}_S$ is a quasi-coherent sheaf of ideals, and \mathcal{F} is a quasi-coherent sheaf on X . Then the lemma says that

$$(46.15.0.1) \quad Rf_*(\mathcal{F}^\wedge) = (Rf_*\mathcal{F})^\wedge$$

where \mathcal{F}^\wedge is the derived completion of \mathcal{F} with respect to $f^{-1}\mathcal{I} \cdot \mathcal{O}_X$ and the right hand side is the derived completion of \mathcal{F} with respect to \mathcal{I} . To see that this gives back the theorem on formal functions we have to do a bit of work. (We will work out what it means in the setting of the usual theorem on formal functions, but dear reader, we encourage you to try and discover new variants of the theorem on formal functions by using this in other cases.)

Lemma 46.15.1. *Let X be a scheme. Let (K_n) be an inverse system of $D_{Qcoh}(\mathcal{O}_X)$ such that the maps $H^q(K_{n+1}) \rightarrow H^q(K_n)$ are surjective for all $q \in \mathbf{Z}$ and $n \geq 1$. Then the derived limit $K = R\mathrm{lim} K_n$ in $D(\mathcal{O}_X)$ has cohomology sheaves $H^q(K) = \mathrm{lim} H^q(K_n)$. Moreover, $R\mathrm{lim} H^q(K_n) = \mathrm{lim} H^q(K_n)$.*

Proof. This follows from Cohomology on Sites, Lemma 21.22.5. Namely, let \mathcal{B} be the set of affine opens of X_{Zar} . The required vanishing follows from Cohomology of Schemes, Lemma 29.2.2 and the vanishing of $R^1 \lim$ because the transition maps $H^0(U, H^q(K_{n+1})) \rightarrow H^0(U, H^q(K_n))$ are surjective for affine open subschemes of X by Schemes, Lemma 25.7.5. \square

Lemma 46.15.2. *Let X be a Noetherian scheme. Let $\mathcal{I} \subset \mathcal{O}_X$ be a quasi-coherent sheaf of ideals.*

- (1) *A coherent \mathcal{O}_X -module \mathcal{F} has derived completion \mathcal{F}^\wedge equal to $\lim \mathcal{F}/\mathcal{I}^n \mathcal{F}$.*
- (2) *A pseudo-coherent object K of $D(\mathcal{O}_X)$ has derived completion K^\wedge with cohomology sheaves $H^q(K^\wedge)$ equal to $H^q(K)^\wedge$.*

Proof. Proof of (1). Since derived completion commutes with localization (Remark 46.14.13) we may assume $X = \text{Spec}(A)$ and $\mathcal{I} = \tilde{I}$ for an ideal $I \subset A$. Say $I = (f_1, \dots, f_r)$. Let $K_n = K(A, f_1^n, \dots, f_r^n)$ be the Koszul complex. By Lemma 46.14.9 the derived completion of \mathcal{F} is given by $R \lim \mathcal{F} \otimes_A K_n$. Let $U = \text{Spec}(B) \subset X$ be an affine open. Since $R\Gamma(U, -)$ commutes with $R \lim$ (Injectives, Lemma 19.13.6) we see that

$$R\Gamma(U, \mathcal{F}^\wedge) = R \lim \mathcal{F}(U) \otimes_A K_n$$

This is the derived completion of $\mathcal{F}(U)$ with respect to IB by More on Algebra, Lemma 15.64.16 and the fact that $K_n \otimes_A B = K(B, f_1^n, \dots, f_r^n)$. By More on Algebra, Lemma 15.64.20 we conclude that $R\Gamma(U, \mathcal{F}^\wedge)$ has vanishing cohomology in degrees different from 0 and $H^0(U, \mathcal{F}^\wedge)$ is the completion of $\mathcal{F}(U)$ in degree 0. Since the affine opens form a basis for the topology, the lemma follows.

Part (2) can either be proved in exactly the same manner as part (1) or it can be deduced from part (1) using the derived completion is an exact functor between triangulated categories. Details omitted. \square

Lemma 46.15.3. *Let $S = \text{Spec}(A)$ be an affine Noetherian scheme. Let $I \subset A$ be an ideal and let $\mathcal{I} \subset \mathcal{O}_S$ be the corresponding quasi-coherent sheaf of ideals. Let K be a pseudo-coherent object of $D(\mathcal{O}_S)$ with derived completion K^\wedge . Then*

$$H^p(S, K^\wedge) = H^p(S, K)^\wedge = \lim H^p(S, K)/I^n H^p(S, K)$$

Proof. Follows from Lemma 46.15.2 and the fact that $R\Gamma(S, -)$ commutes with derived limits. Alternately one could prove this by applying Lemma 46.14.18 to the morphism of ringed spaces $(S, \mathcal{O}_S) \rightarrow (pt, A)$ and using More on Algebra, Lemma 15.64.20. \square

Lemma 46.15.4. *Let $f : X \rightarrow S$ be a morphism of Noetherian schemes with $S = \text{Spec}(A)$ affine. Let $I \subset A$ be an ideal. Let \mathcal{F} be a coherent \mathcal{O}_X -module. Assume that $Rf_* \mathcal{F}$ is a bounded complex with coherent cohomology sheaves. Then there are short exact sequences*

$$0 \rightarrow R^1 \lim H^{p-1}(X, \mathcal{F}/I^n \mathcal{F}) \rightarrow H^p(X, \mathcal{F})^\wedge \rightarrow \lim H^p(X, \mathcal{F}/I^n \mathcal{F}) \rightarrow 0$$

of A -modules. If f is proper, then the $R^1 \lim$ term is zero.

Proof. We are going to prove this by working out what (46.15.0.1) means in this setting. Let us apply $H^p(-)$ to obtain

$$H^p(X, \mathcal{F}^\wedge) = H^p(S, (Rf_* \mathcal{F})^\wedge)$$

Lemma 46.15.3 tells us that the right hand side is equal to

$$H^p(S, Rf_*\mathcal{F})^\wedge = H^p(X, \mathcal{F})^\wedge = \lim H^p(X, \mathcal{F}/I^n\mathcal{F}).$$

On the other hand, Lemmas 46.15.2 and 46.15.1 tell us that $\mathcal{F}^\wedge = \lim \mathcal{F}/I^n\mathcal{F} = R\lim \mathcal{F}/I^n\mathcal{F}$. Since $R\Gamma(X, -)$ commutes with derived limits we obtain for LHS

$$H^p(X, \mathcal{F}^\wedge) = H^p(R\lim R\Gamma(X, \mathcal{F}/I^n\mathcal{F}))$$

By More on Algebra, Remark 15.61.16 we obtain exact sequences as in the statement of the lemma. The vanishing of the $R^1\lim$ term follows from Cohomology of Schemes, Lemma 29.18.4. \square

Remark 46.15.5. Here are some references to discussions of related material the literature. It seems that a “derived formal functions theorem” for proper maps goes back to [Lur04, Theorem 6.3.1]. There is the discussion in [Lur11], especially Chapter 4 which discusses the affine story, see More on Algebra, Section 15.64. In [GR13, Section 2.9] one finds a discussion of proper base change and derived completion using (ind) coherent modules. An analogue of (46.15.0.1) for complexes of quasi-coherent modules can be found as [HLP14, Theorem 6.5]

46.16. Derived completion in the constant Noetherian case

Let \mathcal{C} be a site. Let Λ be a Noetherian ring and let $I \subset \Lambda$ be an ideal. Recall from Modules on Sites, Lemma 18.41.4 that

$$\underline{\Lambda}^\wedge = \lim \underline{\Lambda}/I^n$$

is a flat $\underline{\Lambda}$ -algebra and that the map $\underline{\Lambda} \rightarrow \underline{\Lambda}^\wedge$ identifies quotients by I . Hence Lemma 46.14.16 tells us that

$$D_{comp}(\mathcal{C}, \Lambda) = D_{comp}(\mathcal{C}, \underline{\Lambda}^\wedge)$$

In particular the cohomology sheaves $H^i(K)$ of an object K of $D_{comp}(\mathcal{C}, \Lambda)$ are sheaves of $\underline{\Lambda}^\wedge$ -modules. For notational convenience we often work with $D_{comp}(\mathcal{C}, \Lambda)$.

Lemma 46.16.1. *Let \mathcal{C} be a site. Let Λ be a Noetherian ring and let $I \subset \Lambda$ be an ideal. The left adjoint to the inclusion functor $D_{comp}(\mathcal{C}, \Lambda) \rightarrow D(\mathcal{C}, \Lambda)$ of Proposition 46.14.12 sends K to*

$$K^\wedge = R\lim(K \otimes_\Lambda^L \underline{\Lambda}/I^n)$$

In particular, K is derived complete if and only if $K = R\lim(K \otimes_\Lambda^L \underline{\Lambda}/I^n)$.

Proof. Choose generators f_1, \dots, f_r of I . By Lemma 46.14.9 we have

$$K^\wedge = R\lim(K \otimes_\Lambda^L K_n)$$

where $K_n = K(\Lambda, f_1^n, \dots, f_r^n)$. In More on Algebra, Lemma 15.64.18 we have seen that the pro-systems $\{K_n\}$ and $\{\Lambda/I^n\}$ of $D(\Lambda)$ are isomorphic. Thus the lemma follows. \square

Lemma 46.16.2. *Let Λ be a Noetherian ring. Let $I \subset \Lambda$ be an ideal. Let $f : Sh(\mathcal{D}) \rightarrow Sh(\mathcal{C})$ be a morphism of topoi. Then*

- (1) Rf_* sends $D_{comp}(\mathcal{D}, \Lambda)$ into $D_{comp}(\mathcal{C}, \Lambda)$,
- (2) the map $Rf_* : D_{comp}(\mathcal{D}, \Lambda) \rightarrow D_{comp}(\mathcal{C}, \Lambda)$ has a left adjoint $Lf_{comp}^* : D_{comp}(\mathcal{C}, \Lambda) \rightarrow D_{comp}(\mathcal{D}, \Lambda)$ which is Lf^* followed by derived completion,
- (3) Rf_* commutes with derived completion,

- (4) for K in $D_{comp}(\mathcal{D}, \Lambda)$ we have $Rf_*K = R\lim Rf_*(K \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda/I^n})$.
- (5) for M in $D_{comp}(\mathcal{C}, \Lambda)$ we have $Lf_{comp}^*M = R\lim Lf^*(M \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda/I^n})$.

Proof. We have seen (1) and (2) in Lemma 46.14.17. Part (3) follows from Lemma 46.14.18. For (4) let K be derived complete. Then

$$Rf_*K = Rf_*(R\lim K \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda/I^n}) = R\lim Rf_*(K \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda/I^n})$$

the first equality by Lemma 46.16.1 and the second because Rf_* commutes with $R\lim$ (Cohomology on Sites, Lemma 21.21.2). This proves (4). To prove (5), by Lemma 46.16.1 we have

$$Lf_{comp}^*M = R\lim(Lf^*M \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda/I^n})$$

Since Lf^* commutes with derived tensor product by Cohomology on Sites, Lemma 21.18.4 and since $Lf^*\underline{\Lambda/I^n} = \underline{\Lambda/I^n}$ we get (5). \square

46.17. Derived completion on the pro-étale site

Let \mathcal{C} be a site. Let Λ be a Noetherian ring. Let $I \subset \Lambda$ be an ideal. Although the general theory (see Sections 46.14 and 46.16) concerning $D_{comp}(\mathcal{C}, \Lambda)$ is quite satisfactory it is somewhat useless as it is hard to explicitly give examples of derived complete complexes. We know that

- (1) every object M of $D(\mathcal{C}, \Lambda/I^n)$ restricts to a derived complete object of $D(\mathcal{C}, \Lambda)$, and
- (2) for every $K \in D(\mathcal{C}, \Lambda)$ the derived completion $K^\wedge = R\lim(K \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda/I^n})$ is derived complete.

The first type of objects are trivially complete and perhaps not interesting. The problem with (2) is that derived completion in general is somewhat mysterious, even in case $K = \underline{\Lambda}$. Namely, by definition of homotopy limits there is a distinguished triangle

$$R\lim(\underline{\Lambda/I^n}) \rightarrow \prod \underline{\Lambda/I^n} \rightarrow \prod \underline{\Lambda/I^n} \rightarrow R\lim(\underline{\Lambda/I^n})[1]$$

in $D(\mathcal{C}, \Lambda)$ where the products are in $D(\mathcal{C}, \Lambda)$. These are computed by taking products of injective resolutions (Injectives, Lemma 19.13.4), so we see that the sheaf $H^p(\prod \underline{\Lambda/I^n})$ is the sheafification of the presheaf

$$U \mapsto \prod H^p(U, \underline{\Lambda/I^n}).$$

As an explicit example, if $X = \text{Spec}(\mathbf{C}[t, t^{-1}])$, $\mathcal{C} = X_{\acute{e}tale}$, $\Lambda = \mathbf{Z}$, $I = (2)$, and $p = 1$, then we get the sheafification of the presheaf

$$U \mapsto \prod H^1(U_{\acute{e}tale}, \mathbf{Z}/2^n\mathbf{Z})$$

for U étale over X . Note that $H^1(X_{\acute{e}tale}, \mathbf{Z}/m\mathbf{Z})$ is cyclic of order m with generator α_m given by the finite étale $\mathbf{Z}/m\mathbf{Z}$ -covering given by the equation $t = s^m$ (see Étale Cohomology, Section 44.6). Then the section

$$\alpha = (\alpha_{2^n}) \in \prod H^1(X_{\acute{e}tale}, \mathbf{Z}/2^n\mathbf{Z})$$

of the presheaf above does not restrict to zero on any nonempty étale scheme over X , whence the sheaf associated to the presheaf is not zero.

However, on the pro-étale site this phenomenon does not occur. The reason is that we have enough (quasi-compact) weakly contractible objects. In the following

proposition we collect some results about derived completion in the Noetherian constant case for sites having enough weakly contractible objects (see Sites, Definition 7.39.2).

Proposition 46.17.1. *Let \mathcal{C} be a site. Assume \mathcal{C} has enough weakly contractible objects. Let Λ be a Noetherian ring. Let $I \subset \Lambda$ be an ideal.*

- (1) *The category of derived complete sheaves Λ -modules is a weak Serre subcategory of $\text{Mod}(\mathcal{C}, \Lambda)$.*
- (2) *A sheaf \mathcal{F} of Λ -modules satisfies $\mathcal{F} = \lim \mathcal{F}/I^n \mathcal{F}$ if and only if \mathcal{F} is derived complete and $\bigcap I^n \mathcal{F} = 0$.*
- (3) *The sheaf $\underline{\Lambda}^\wedge$ is derived complete.*
- (4) *If $\dots \rightarrow \mathcal{F}_3 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_1$ is an inverse system of derived complete sheaves of Λ -modules, then $\lim \mathcal{F}_n$ is derived complete.*
- (5) *An object $K \in D(\mathcal{C}, \Lambda)$ is derived complete if and only if each cohomology sheaf $H^p(K)$ is derived complete.*
- (6) *An object $K \in D_{\text{comp}}(\mathcal{C}, \Lambda)$ is bounded above if and only if $K \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda}/I$ is bounded above.*
- (7) *An object $K \in D_{\text{comp}}(\mathcal{C}, \Lambda)$ is bounded if $K \otimes_{\Lambda}^{\mathbf{L}} \underline{\Lambda}/I$ has finite tor dimension.*

Proof. Let $\mathcal{B} \subset \text{Ob}(\mathcal{C})$ be a subset such that every $U \in \mathcal{B}$ is weakly contractible and every object of \mathcal{C} has a covering by elements of \mathcal{B} . We will use the results of Cohomology on Sites, Lemma 21.38.1 and Proposition 21.38.2 without further mention.

Recall that $R\lim$ commutes with $R\Gamma(U, -)$, see Injectives, Lemma 19.13.6. Let $f \in I$. Recall that $T(K, f)$ is the homotopy limit of the system

$$\dots K \xrightarrow{f} K \xrightarrow{f} K$$

in $D(\mathcal{C}, \Lambda)$. Thus

$$R\Gamma(U, T(K, f)) = T(R\Gamma(U, K), f).$$

Since we can test isomorphisms of maps between objects of $D(\mathcal{C}, \Lambda)$ by evaluating at $U \in \mathcal{B}$ we conclude an object K of $D(\mathcal{C}, \Lambda)$ is derived complete if and only if for every $U \in \mathcal{B}$ the object $R\Gamma(U, K)$ is derived complete as an object of $D(\Lambda)$.

The remark above implies that items (1), (5) follow from the corresponding results for modules over rings, see More on Algebra, Lemmas 15.64.1 and 15.64.6. In the same way (2) can be deduced from More on Algebra, Proposition 15.64.5 as $(I^n \mathcal{F})(U) = I^n \cdot \mathcal{F}(U)$ for $U \in \mathcal{B}$ (by exactness of evaluating at U).

Proof of (4). The homotopy limit $R\lim \mathcal{F}_n$ is in $D_{\text{comp}}(\mathcal{C}, \Lambda)$ (see discussion following Definition 46.14.4). By part (5) just proved we conclude that $\lim \mathcal{F}_n = H^0(R\lim \mathcal{F}_n)$ is derived complete. Part (3) is a special case of (4).

Proof of (6) and (7). Follows from Lemma 46.16.1 and Cohomology on Sites, Lemma 21.35.8 and the computation of homotopy limits in Cohomology on Sites, Proposition 21.38.2. \square

46.18. Comparison with the étale site

Let X be a scheme. With suitable choices of sites (as in Topologies, Remark 33.9.1) the functor $u : X_{\text{étale}} \rightarrow X_{\text{pro-étale}}$ sending U/X to U/X defines a morphism of sites

$$\epsilon : X_{\text{pro-étale}} \longrightarrow X_{\text{étale}}$$

This follows from Sites, Proposition 7.15.6. A fundamental fact about this comparison morphism is the following.

Lemma 46.18.1. *Let X be a scheme. Let $Y = \lim Y_i$ be an inverse limit of quasi-compact and quasi-separated schemes étale over X with affine transition morphisms. For any sheaf \mathcal{F} on $X_{\text{étale}}$ we have $\epsilon^{-1}\mathcal{F}(Y) = \text{colim } \mathcal{F}(Y_i)$.*

Proof. Let $\mathcal{F} = h_U$ be a representable sheaf on $X_{\text{étale}}$ with U an object of $X_{\text{étale}}$. In this case $\epsilon^{-1}h_U = h_{u(U)}$ where $u(U)$ is U viewed as an object of $X_{\text{pro-étale}}$ (Sites, Lemma 7.14.5). Then

$$h_{u(U)}(Y) = \text{Mor}_X(Y, U) = \text{colim } \text{Mor}_X(Y_i, U) = \text{colim } h_U(Y_i)$$

by Limits, Proposition 31.5.1. Hence the lemma holds for every representable sheaf. Since every sheaf is a coequalizer of a map of coproducts of representable sheaves (Sites, Lemma 7.13.5) we obtain the result in general. \square

Lemma 46.18.2. *Let X be a scheme. For every sheaf \mathcal{F} on $X_{\text{étale}}$ the adjunction map $\mathcal{F} \rightarrow \epsilon_*\epsilon^{-1}\mathcal{F}$ is an isomorphism.*

Proof. Suppose that U is a quasi-compact and quasi-separated scheme étale over X . Then

$$\epsilon_*\epsilon^{-1}\mathcal{F}(U) = \epsilon^{-1}\mathcal{F}(U) = \mathcal{F}(U)$$

the second equality by (a special case of) Lemma 46.18.1. Since every object of $X_{\text{étale}}$ has a covering by quasi-compact and quasi-separated objects we conclude. \square

Lemma 46.18.3. *Let X be an affine scheme. For injective abelian sheaf \mathcal{I} on $X_{\text{étale}}$ we have $H^p(X_{\text{pro-étale}}, \epsilon^{-1}\mathcal{I}) = 0$ for $p > 0$.*

Proof. We are going to use Cohomology on Sites, Lemma 21.11.9 to prove this. The idea is simple: We show that every standard pro-étale covering of X is a limit of coverings in $X_{\text{étale}}$. If this holds then Lemma 46.18.1 will kick in to show the Čech cohomology groups of $\epsilon^{-1}\mathcal{I}$ are colimits of those of \mathcal{I} which are zero in positive degree.

Here are the details. Let $\mathcal{B} \subset \text{Ob}(X_{\text{pro-étale}})$ be the set of affine schemes U over X such that $\mathcal{O}(X) \rightarrow \mathcal{O}(U)$ is ind-étale. Let Cov be the set of pro-étale coverings $\{U_i \rightarrow U\}_{i=1, \dots, n}$ with $U, U_i \in \mathcal{B}$ such that $\mathcal{O}(U) \rightarrow \mathcal{O}(U_i)$ is ind-étale for $i = 1, \dots, n$. Properties (1) and (2) of Cohomology on Sites, Lemma 21.11.9 hold for \mathcal{B} and Cov by Proposition 46.9.1 (it also follows from Lemma 46.11.10).

To check condition (3) suppose that $\{U_i \rightarrow U\}_{i=1, \dots, n}$ is an element of Cov . Then we can write $U_i = \lim_{a \in A_i} U_{i,a}$ with $U_{i,a} \rightarrow U$ étale and $U_{i,a}$ affine. Next we write $U = \lim_{b \in B} U_b$ with U_b affine and $U_b \rightarrow U$ étale. By Limits, Lemma 31.9.1 for each i and $a \in A_i$ we can choose a $b(i, a) \in B$ and for all $b \geq b(i, a)$ an affine scheme

$U_{i,a,b}$ étale over U_b such that $U_{i,a} = \lim_{b \geq b(i,a)} U_{i,a,b}$ ². Moreover, any transition map $U_{i,a} \rightarrow U_{i,a'}$ comes from an essentially unique morphism $U_{i,a,b} \rightarrow U_{i,a',b}$ for b large enough (by the same reference). Finally, given $a_1 \in A_1, \dots, a_n \in A_n$ the morphism $U_{1,a_1} \amalg \dots \amalg U_{n,a_n} \rightarrow U$ is surjective, hence for b large enough the map $U_{1,a_1,b} \amalg \dots \amalg U_{n,a_n,b} \rightarrow U_b$ is surjective by Limits, Lemma 31.7.11. Let \mathcal{D} be the category of coverings $\{U_{i,a_i,b} \rightarrow U_b\}_{i=1,\dots,n}$ so obtained. This category is cofiltered. We claim that, given $i_0, \dots, i_p \in \{1, \dots, n\}$ we have

$$U_{i_0} \times_U U_{i_1} \times_U \dots \times_U U_{i_p} = \lim_{\mathcal{D}} U_{i_0, a_{i_0}, b} \times_{U_b} U_{i_1, a_{i_1}, b} \times_{U_b} \dots \times_{U_b} U_{i_p, a_{i_p}, b}$$

This is clear from the fact that it holds for $p = -1$ (i.e., $U = \lim_{\mathcal{D}} U_b$) and for $p = 0$ (i.e., $U_i = \lim_{\mathcal{D}} U_{i,a_i,b}$) and the fact that fibre products commute with limits. Then finally it follows from Lemma 46.18.1 that

$$\check{C}^\bullet(\{U_i \rightarrow U\}, \epsilon^{-1}\mathcal{I}) = \operatorname{colim}_{\mathcal{D} \circ \text{pp}} \check{C}^\bullet(\{U_{i,a_i,b} \rightarrow U_b\}, \mathcal{I})$$

Since each of the Čech complexes on the right hand side is acyclic in positive degrees (Cohomology on Sites, Lemma 21.11.2) it follows that the one on the left is too. This prove condition (3) of Cohomology on Sites, Lemma 21.11.9. Since $X \in \mathcal{B}$ the lemma follows. \square

Lemma 46.18.4. *Let X be a scheme. For an abelian sheaf \mathcal{F} on $X_{\text{étale}}$ we have $R\epsilon_*(\epsilon^{-1}\mathcal{F}) = \mathcal{F}$.*

Proof. Let \mathcal{I} be an injective abelian sheaf on $X_{\text{étale}}$. Recall that $R^q\epsilon_*(\epsilon^{-1}\mathcal{I})$ is the sheaf associated to $U \mapsto H^q(U_{\text{pro-étale}}, \epsilon^{-1}\mathcal{I})$, see Cohomology on Sites, Lemma 21.8.4. By Lemma 46.18.3 we see that this is zero for $q > 0$ and U affine and étale over X . Since every object of $X_{\text{étale}}$ has a covering by affine objects, it follows that $R^q\epsilon_*(\epsilon^{-1}\mathcal{I}) = 0$ for $q > 0$. Combined with Lemma 46.18.2 we conclude that $R\epsilon_*\epsilon^{-1}\mathcal{I} = \mathcal{I}$ for every injective abelian sheaf. Since every abelian sheaf has a resolution by injective sheaves, the result follows. (Hint: use Leray acyclicity theorem – Derived Categories, Lemma 13.17.7.) \square

Lemma 46.18.5. *Let X be a scheme. For an abelian sheaf \mathcal{F} on $X_{\text{étale}}$ we have*

$$H^i(X_{\text{étale}}, \mathcal{F}) = H^i(X_{\text{pro-étale}}, \epsilon^{-1}\mathcal{F})$$

for all i .

Proof. Immediate consequence of Lemma 46.18.4 and the Leray spectral sequence (Cohomology on Sites, Lemma 21.14.6). \square

Lemma 46.18.6. *Let X be a scheme. Let \mathcal{G} be a sheaf of (possibly noncommutative) groups on $X_{\text{étale}}$. We have*

$$H^1(X_{\text{étale}}, \mathcal{G}) = H^1(X_{\text{pro-étale}}, \epsilon^{-1}\mathcal{G})$$

where H^1 is defined as the set of isomorphism classes of torsors (see Cohomology on Sites, Section 21.5).

Proof. Since the functor ϵ^{-1} is fully faithful by Lemma 46.18.2 it is clear that the map $H^1(X_{\text{étale}}, \mathcal{G}) \rightarrow H^1(X_{\text{pro-étale}}, \epsilon^{-1}\mathcal{G})$ is injective. To show surjectivity it suffices to show that any $\epsilon^{-1}\mathcal{G}$ -torsor \mathcal{F} is étale locally trivial. To do this we may assume that X is affine. Thus we reduce to proving surjectivity for X affine.

²To be sure, we pick $U_{i,a,b} = U_b \times_{U_{b(i,a)}} U_{i,a,b(i,a)}$ although this isn't necessary for what follows.

Choose a covering $\{U \rightarrow X\}$ with (a) U affine, (b) $\mathcal{O}(X) \rightarrow \mathcal{O}(U)$ ind-étale, and (c) $\mathcal{F}(U)$ nonempty. We can do this by Proposition 46.9.1 and the fact that standard pro-étale coverings of X are cofinal among all pro-étale coverings of X (Lemma 46.11.5). Write $U = \lim U_i$ as a limit of affine schemes étale over X . Pick $s \in \mathcal{F}(U)$. Let $g \in \epsilon^{-1}\mathcal{G}(U \times_X U)$ be the unique section such that $g \cdot \text{pr}_1^*s = \text{pr}_2^*s$ in $\mathcal{F}(U \times_X U)$. Then g satisfies the cocycle condition

$$\text{pr}_{12}^*g \cdot \text{pr}_{23}^*g = \text{pr}_{13}^*g$$

in $\epsilon^{-1}\mathcal{G}(U \times_X U \times_X U)$. By Lemma 46.18.1 we have

$$\epsilon^{-1}\mathcal{G}(U \times_X U) = \text{colim } \mathcal{G}(U_i \times_X U_i)$$

and

$$\epsilon^{-1}\mathcal{G}(U \times_X U \times_X U) = \text{colim } \mathcal{G}(U_i \times_X U_i \times_X U_i)$$

hence we can find an i and an element $g_i \in \mathcal{G}(U_i)$ mapping to g satisfying the cocycle condition. The cocycle g_i then defines a torsor for \mathcal{G} on $X_{\text{étale}}$ whose pullback is isomorphic to \mathcal{F} by construction. Some details omitted (namely, the relationship between torsors and 1-cocycles which should be added to the chapter on cohomology on sites). \square

Lemma 46.18.7. *Let X be a scheme. Let Λ be a ring.*

- (1) *The essential image of $\epsilon^{-1} : \text{Mod}(X_{\text{étale}}, \Lambda) \rightarrow \text{Mod}(X_{\text{pro-étale}}, \Lambda)$ is a weak Serre subcategory \mathcal{C} .*
- (2) *The functor ϵ^{-1} defines an equivalence of categories of $D^+(X_{\text{étale}}, \Lambda)$ with $D_{\mathcal{C}}^+(X_{\text{pro-étale}}, \Lambda)$.*

Proof. To prove (1) we will prove conditions (1) – (4) of Homology, Lemma 12.9.3. Since ϵ^{-1} is fully faithful (Lemma 46.18.2) and exact, everything is clear except for condition (4). However, if

$$0 \rightarrow \epsilon^{-1}\mathcal{F}_1 \rightarrow \mathcal{G} \rightarrow \epsilon^{-1}\mathcal{F}_2 \rightarrow 0$$

is a short exact sequence of sheaves of Λ -modules on $X_{\text{pro-étale}}$, then we get

$$0 \rightarrow \epsilon_*\epsilon^{-1}\mathcal{F}_1 \rightarrow \epsilon_*\mathcal{G} \rightarrow \epsilon_*\epsilon^{-1}\mathcal{F}_2 \rightarrow R^1\epsilon_*\epsilon^{-1}\mathcal{F}_1$$

which by Lemma 46.18.4 is the same as a short exact sequence

$$0 \rightarrow \mathcal{F}_1 \rightarrow \epsilon_*\mathcal{G} \rightarrow \mathcal{F}_2 \rightarrow 0$$

Pulling pack we find that $\mathcal{G} = \epsilon^{-1}\epsilon_*\mathcal{G}$. This proves (1).

By (1) and the discussion in Derived Categories, Section 13.13 we obtain a strictly full, saturated, triangulated subcategory $D_{\mathcal{C}}(X_{\text{pro-étale}}, \Lambda)$. It is clear that ϵ^{-1} maps $D(X_{\text{étale}}, \Lambda)$ into $D_{\mathcal{C}}(X_{\text{pro-étale}}, \Lambda)$. If M is in $D^+(X_{\text{étale}}, \Lambda)$, then Lemma 46.18.4 shows that $M \rightarrow R\epsilon_*\epsilon^{-1}M$ is an isomorphism. If K is in $D_{\mathcal{C}}^+(X_{\text{pro-étale}}, \Lambda)$, then the spectral sequence

$$R^q\epsilon_*H^p(K) \Rightarrow H^{p+q}(R\epsilon_*K)$$

and the vanishing in Lemma 46.18.4 shows that $H^p(R\epsilon_*K) = R\epsilon_*H^p(K)$. Since ϵ is a flat morphism of ringed sites (ringed by the constant sheaf $\underline{\Lambda}$) we see that $\epsilon^{-1}R\epsilon_*K$ has cohomology sheaves $\epsilon^{-1}R\epsilon_*H^p(K)$. Since we've assumed $H^p(K)$ is in \mathcal{C} we conclude by Lemma 46.18.4 once more that $\epsilon^{-1}R\epsilon_*K \rightarrow K$ is an isomorphism. In this way we see that ϵ^{-1} and $R\epsilon_*$ are quasi-inverse functors proving (2). \square

Let Λ be a ring. In Modules on Sites, Section 18.42 we have defined the notion of a locally constant sheaf of Λ -modules on a site. If M is a Λ -module, then \underline{M} is of finite presentation as a sheaf of $\underline{\Lambda}$ -modules if and only if M is a finitely presented Λ -module, see Modules on Sites, Lemma 18.41.5.

Lemma 46.18.8. *Let X be a scheme. Let Λ be a ring. The functor ϵ^{-1} defines an equivalence of categories*

$$\left\{ \begin{array}{l} \text{locally constant sheaves} \\ \text{of } \Lambda\text{-modules on } X_{\acute{e}tale} \\ \text{of finite presentation} \end{array} \right\} \longleftrightarrow \left\{ \begin{array}{l} \text{locally constant sheaves} \\ \text{of } \Lambda\text{-modules on } X_{\text{pro-}\acute{e}tale} \\ \text{of finite presentation} \end{array} \right\}$$

Proof. Let \mathcal{F} be a locally constant sheaf of Λ -modules on $X_{\text{pro-}\acute{e}tale}$ of finite presentation. Choose a pro-étale covering $\{U_i \rightarrow X\}$ such that $\mathcal{F}|_{U_i}$ is constant, say $\mathcal{F}|_{U_i} \cong \underline{M}_{i|U_i}$. Observe that $U_i \times_X U_j$ is empty if M_i is not isomorphic to M_j . For each Λ -module M let $I_M = \{i \in I \mid M_i \cong M\}$. As pro-étale coverings are fpqc coverings and by Descent, Lemma 34.9.2 we see that $U_M = \bigcup_{i \in I_M} \text{Im}(U_i \rightarrow X)$ is an open subset of X . Then $X = \coprod U_M$ is a disjoint open covering of X . We may replace X by U_M for some M and assume that $M_i = M$ for all i .

Consider the sheaf $\mathcal{I} = \text{Isom}(\underline{M}, \mathcal{F})$. This sheaf is a torsor for $\mathcal{G} = \text{Isom}(\underline{M}, \underline{M})$. By Modules on Sites, Lemma 18.42.4 we have $\mathcal{G} = \underline{G}$ where $G = \text{Isom}_{\Lambda}(M, M)$. Since torsors for the étale topology and the pro-étale topology agree by Lemma 46.18.6 it follows that \mathcal{I} has sections étale locally on X . Thus \mathcal{F} is étale locally a constant sheaf which is what we had to show. \square

Lemma 46.18.9. *Let X be a scheme. Let Λ be a Noetherian ring. Let $D_{\text{flc}}(X_{\acute{e}tale}, \Lambda)$, resp. $D_{\text{flc}}(X_{\text{pro-}\acute{e}tale}, \Lambda)$ be the full subcategory of $D(X_{\acute{e}tale}, \Lambda)$, resp. $D(X_{\text{pro-}\acute{e}tale}, \Lambda)$ consisting of those complexes whose cohomology sheaves are locally constant sheaves of Λ -modules of finite type. Then*

$$\epsilon^{-1} : D_{\text{flc}}^+(X_{\acute{e}tale}, \Lambda) \longrightarrow D_{\text{flc}}^+(X_{\text{pro-}\acute{e}tale}, \Lambda)$$

is an equivalence of categories.

Proof. The categories $D_{\text{flc}}(X_{\acute{e}tale}, \Lambda)$ and $D_{\text{flc}}(X_{\text{pro-}\acute{e}tale}, \Lambda)$ are strictly full, saturated, triangulated subcategories of $D(X_{\acute{e}tale}, \Lambda)$ and $D(X_{\text{pro-}\acute{e}tale}, \Lambda)$ by Modules on Sites, Lemma 18.42.5 and Derived Categories, Section 13.13 The statement of the lemma follows by combining Lemmas 46.18.7 and 46.18.8. \square

Lemma 46.18.10. *Let X be a scheme. Let Λ be a Noetherian ring. Let K be an object of $D(X_{\text{pro-}\acute{e}tale}, \Lambda)$. Set $K_n = K \otimes_{\Lambda}^{\mathbf{L}} \Lambda/I^n$. If K_1 is*

- (1) *in the essential image of $\epsilon^{-1} : D(X_{\acute{e}tale}, \Lambda/I) \rightarrow D(X_{\text{pro-}\acute{e}tale}, \Lambda/I)$, and*
- (2) *has tor amplitude in $[a, \infty)$ for some $a \in \mathbf{Z}$,*

then (1) and (2) hold for K_n as an object of $D(X_{\text{pro-}\acute{e}tale}, \Lambda/I^n)$.

Proof. For assertion (2) this follows from the more general Cohomology on Sites, Lemma 21.35.8. The second assertion follows from the fact that the essential image of ϵ^{-1} is a triangulated subcategory of $D^+(X_{\text{pro-}\acute{e}tale}, \Lambda/I^n)$ (Lemma 46.18.7), the distinguished triangles

$$K \otimes_{\Lambda}^{\mathbf{L}} \underline{I^n/I^{n+1}} \rightarrow K_{n+1} \rightarrow K_n \rightarrow K \otimes_{\Lambda}^{\mathbf{L}} \underline{I^n/I^{n+1}}[1]$$

and the isomorphism

$$K \otimes_{\Lambda}^{\mathbf{L}} \underline{I^n/I^{n+1}} = K_1 \otimes_{\Lambda/I}^{\mathbf{L}} \underline{I^n/I^{n+1}}$$

□

46.19. Cohomology of a point

Let Λ be a Noetherian ring complete with respect to an ideal $I \subset \Lambda$. Let k be a field. In this section we “compute”

$$H^i(\mathrm{Spec}(k)_{\mathrm{pro\text{-}\acute{e}tale}}, \underline{\Lambda}^\wedge)$$

where $\underline{\Lambda}^\wedge = \varprojlim \underline{\Lambda/I^n}$ as before. Let k^{sep} be a separable algebraic closure of k . Then

$$\mathcal{U} = \{\mathrm{Spec}(k^{\mathrm{sep}}) \rightarrow \mathrm{Spec}(k)\}$$

is a pro-étale covering of $\mathrm{Spec}(k)$. We will use the Čech to cohomology spectral sequence with respect to this covering. Set $U_0 = \mathrm{Spec}(k^{\mathrm{sep}})$ and

$$\begin{aligned} U_n &= \mathrm{Spec}(k^{\mathrm{sep}}) \times_{\mathrm{Spec}(k)} \mathrm{Spec}(k^{\mathrm{sep}}) \times_{\mathrm{Spec}(k)} \cdots \times_{\mathrm{Spec}(k)} \mathrm{Spec}(k^{\mathrm{sep}}) \\ &= \mathrm{Spec}(k^{\mathrm{sep}} \otimes_k k^{\mathrm{sep}} \otimes_k \cdots \otimes_k k^{\mathrm{sep}}) \end{aligned}$$

($n + 1$ factors). Note that the underlying topological space $|U_0|$ of U_0 is a singleton and for $n \geq 1$ we have

$$|U_n| = G \times \cdots \times G \quad (n \text{ factors})$$

as profinite spaces where $G = \mathrm{Gal}(k^{\mathrm{sep}}/k)$. Namely, every point of U_n has residue field k^{sep} and we identify $(\sigma_1, \dots, \sigma_n)$ with the point corresponding to the surjection

$$k^{\mathrm{sep}} \otimes_k k^{\mathrm{sep}} \otimes_k \cdots \otimes_k k^{\mathrm{sep}} \longrightarrow k^{\mathrm{sep}}, \quad \lambda_0 \otimes \lambda_1 \otimes \cdots \otimes \lambda_n \longmapsto \lambda_0 \sigma_1(\lambda_1) \cdots \sigma_n(\lambda_n)$$

Then we compute

$$\begin{aligned} R\Gamma((U_n)_{\mathrm{pro\text{-}\acute{e}tale}}, \underline{\Lambda}^\wedge) &= R\lim R\Gamma((U_n)_{\mathrm{pro\text{-}\acute{e}tale}}, \underline{\Lambda/I^n}) \\ &= R\lim R\Gamma((U_n)_{\acute{e}tale}, \underline{\Lambda/I^n}) \\ &= \lim H^0(U_n, \underline{\Lambda/I^n}) \\ &= \mathrm{Maps}_{\mathrm{cont}}(G \times \cdots \times G, \Lambda) \end{aligned}$$

The first equality because $R\Gamma$ commutes with derived limits and as $\underline{\Lambda}^\wedge$ is the derived limit of the sheaves $\underline{\Lambda/I^n}$ by Proposition 46.17.1. The second equality by Lemma 46.18.5. The third equality by Étale Cohomology, Lemma 44.55.7. The fourth equality uses Étale Cohomology, Remark 44.23.2 to identify sections of the constant sheaf $\underline{\Lambda/I^n}$. Then it uses the fact that Λ is complete with respect to I and hence equal to $\varprojlim \underline{\Lambda/I^n}$ as a topological space, to see that $\lim \mathrm{Map}_{\mathrm{cont}}(G, \underline{\Lambda/I^n}) = \mathrm{Map}_{\mathrm{cont}}(G, \Lambda)$ and similarly for higher powers of G . At this point Cohomology on Sites, Lemmas 21.11.3 and 21.11.7 tell us that

$$\Lambda \rightarrow \mathrm{Maps}_{\mathrm{cont}}(G, \Lambda) \rightarrow \mathrm{Maps}_{\mathrm{cont}}(G \times G, \Lambda) \rightarrow \cdots$$

computes the pro-étale cohomology. In other words, we see that

$$H^i(\mathrm{Spec}(k)_{\mathrm{pro\text{-}\acute{e}tale}}, \underline{\Lambda}^\wedge) = H^i_{\mathrm{cont}}(G, \Lambda)$$

where the right hand side is continuous cohomology as defined by Tate in [Tat76]. Of course, this is as it should be.

Lemma 46.19.1. *Let k be a field. Let $G = \mathrm{Gal}(k^{\mathrm{sep}}/k)$ be its absolute Galois group. Further,*

- (1) *let M be a profinite abelian group with a continuous G -action, or*

- (2) let Λ be a Noetherian ring and $I \subset \Lambda$ an ideal and let M be an I -adically complete Λ -module with continuous G -action.

Then there is a canonical sheaf \underline{M}^\wedge on $\mathrm{Spec}(k)_{\mathrm{pro-étale}}$ associated to M such that

$$H^i(\mathrm{Spec}(k), \underline{M}^\wedge) = H_{\mathrm{cont}}^i(G, M)$$

as abelian groups or Λ -modules.

Proof. Proof in case (2). Set $M_n = M/I^n M$. Then $M = \varinjlim M_n$ as M is assumed I -adically complete. Since the action of G is continuous we get continuous actions of G on M_n . By Étale Cohomology, Theorem 44.57.3 this action corresponds to a (locally constant) sheaf \underline{M}_n of Λ/I^n -modules on $\mathrm{Spec}(k)_{\mathrm{étale}}$. Pull back to $\mathrm{Spec}(k)_{\mathrm{pro-étale}}$ by the comparison morphism ϵ and take the limit

$$\underline{M}^\wedge = \varinjlim \epsilon^{-1} \underline{M}_n$$

to get the sheaf promised in the lemma. Exactly the same argument as given in the introduction of this section gives the comparison with Tate's continuous Galois cohomology. \square

46.20. Weakly contractible hypercoverings

Let X be a scheme. For every object $U \in \mathrm{Ob}(X_{\mathrm{pro-étale}})$ there exists a covering $\{V \rightarrow U\}$ of $X_{\mathrm{pro-étale}}$ with V weakly contractible. This follows from Lemma 46.11.10 and the elementary fact that a disjoint union of weakly contractible objects in $X_{\mathrm{pro-étale}}$ is weakly contractible (discussion of set theoretic issues omitted). This observation leads to the existence of hypercoverings made up out weakly contractible objects.

Lemma 46.20.1. *Let X be a scheme.*

- (1) *For every object U of $X_{\mathrm{pro-étale}}$ there exists a hypercovering K of U in $X_{\mathrm{pro-étale}}$ such that each term K_n consists of a single weakly contractible object of $X_{\mathrm{pro-étale}}$ covering U .*
- (2) *For every quasi-compact and quasi-separated object U of $X_{\mathrm{pro-étale}}$ there exists a hypercovering K of U in $X_{\mathrm{pro-étale}}$ such that each term K_n consists of a single affine and weakly contractible object of $X_{\mathrm{pro-étale}}$ covering U .*

Proof. Let $\mathcal{B} \subset \mathrm{Ob}(X_{\mathrm{pro-étale}})$ be the set of weakly contractible objects of $X_{\mathrm{pro-étale}}$. We have seen above that every object of $X_{\mathrm{pro-étale}}$ has a covering by an element of \mathcal{B} . Apply Hypercoverings, Lemma 24.11.1 to get (1).

Let $X_{\mathrm{qcqs,pro-étale}} \subset X_{\mathrm{pro-étale}}$ be the full subcategory consisting of quasi-compact and quasi-separated objects. Note that $X_{\mathrm{qcqs,pro-étale}}$ is preserved under fibre products. A covering of $X_{\mathrm{qcqs,pro-étale}}$ will be a finite pro-étale covering. Then $X_{\mathrm{qcqs,pro-étale}} \rightarrow X_{\mathrm{pro-étale}}$ is a special cocontinuous functor hence $X_{\mathrm{qcqs,pro-étale}}$ defines the same topos as $X_{\mathrm{pro-étale}}$. Details omitted; see Sites, Definition 7.28.2 and Lemma 7.28.1. In particular, if K is a hypercovering of an object U in $X_{\mathrm{qcqs,pro-étale}}$ then K is a hypercovering of $X_{\mathrm{pro-étale}}$. Let $\mathcal{B} \subset \mathrm{Ob}(X_{\mathrm{qcqs,pro-étale}})$ be the set of affine and weakly contractible objects. By Lemma 46.11.10 and the fact that finite unions of affines are affine, for every object U of $X_{\mathrm{qcqs,pro-étale}}$ there exists a covering $\{V \rightarrow U\}$ of $X_{\mathrm{qcqs,pro-étale}}$ with $V \in \mathcal{B}$. Apply Hypercoverings, Lemma 24.11.1 to get (2). \square

In the following lemma we use the Čech complex $\mathcal{F}(K)$ associated to a hypercovering K in a site. See Hypercoverings, Section 24.4. If K is a hypercovering of U and $K_n = \{U_n \rightarrow U\}$, then the Čech complex looks like this:

$$\mathcal{F}(K) = (\mathcal{F}(U_0) \rightarrow \mathcal{F}(U_1) \rightarrow \mathcal{F}(U_2) \rightarrow \dots)$$

Lemma 46.20.2. *Let X be a scheme. Let $E \in D^+(X_{\text{pro-étale}})$ be represented by a bounded below complex \mathcal{E}^\bullet of abelian sheaves. Let K be a hypercovering of $U \in \text{Ob}(X_{\text{pro-étale}})$ with $K_n = \{U_n \rightarrow U\}$ where U_n is a weakly contractible object of $X_{\text{pro-étale}}$. Then*

$$R\Gamma(U, E) = \text{Tot}(\mathcal{E}^\bullet(K))$$

in $D(\text{Ab})$.

Proof. If $E = \mathcal{E}[n]$ is the object associated to a single abelian sheaf on $X_{\text{pro-étale}}$, then the spectral sequence of Hypercoverings, Lemma 24.4.3 implies that

$$R\Gamma(X_{\text{pro-étale}}, \mathcal{E}) = \mathcal{E}(K)$$

because the higher cohomology groups of any sheaf over U_n vanish, see Cohomology on Sites, Lemma 21.38.1.

If \mathcal{E}^\bullet is bounded below, then we can choose an injective resolution $\mathcal{E}^\bullet \rightarrow \mathcal{I}^\bullet$ and consider the map of complexes

$$\text{Tot}(\mathcal{E}^\bullet(K)) \longrightarrow \text{Tot}(\mathcal{I}^\bullet(K))$$

For every n the map $\mathcal{E}^\bullet(U_n) \rightarrow \mathcal{I}^\bullet(U_n)$ is a quasi-isomorphism because taking sections over U_n is exact. Hence the displayed map is a quasi-isomorphism by one of the spectral sequences of Homology, Lemma 12.22.6. Using the result of the first paragraph we see that for every p the complex $\mathcal{I}^p(K)$ is acyclic in degrees $n > 0$ and computes $\mathcal{I}^p(U)$ in degree 0. Thus the other spectral sequence of Homology, Lemma 12.22.6 shows $\text{Tot}(\mathcal{I}^\bullet(K))$ computes $R\Gamma(U, E) = \mathcal{I}^\bullet(U)$. \square

Lemma 46.20.3. *Let X be a quasi-compact and quasi-separated scheme. The functor $R\Gamma(X, -) : D^+(X_{\text{pro-étale}}) \rightarrow D(\text{Ab})$ commutes with direct sums and homotopy colimits.*

Proof. The statement means the following: Suppose we have a family of objects E_i of $D^+(X_{\text{pro-étale}})$ such that $\bigoplus E_i$ is an object of $D^+(X_{\text{pro-étale}})$. Then $R\Gamma(X, \bigoplus E_i) = \bigoplus R\Gamma(X, E_i)$. To see this choose a hypercovering K of X with $K_n = \{U_n \rightarrow X\}$ where U_n is an affine and weakly contractible scheme, see Lemma 46.20.1. Let N be an integer such that $H^p(E_i) = 0$ for $p < N$. Choose a complex of abelian sheaves \mathcal{E}_i^\bullet representing E_i with $\mathcal{E}_i^p = 0$ for $p < N$. The termwise direct sum $\bigoplus \mathcal{E}_i^\bullet$ represents $\bigoplus E_i$ in $D(X_{\text{pro-étale}})$, see Injectives, Lemma 19.13.4. By Lemma 46.20.2 we have

$$R\Gamma(X, \bigoplus E_i) = \text{Tot}(\bigoplus \mathcal{E}_i^\bullet(K))$$

and

$$R\Gamma(X, E_i) = \text{Tot}(\mathcal{E}_i^\bullet(K))$$

Since each U_n is quasi-compact we see that

$$\text{Tot}(\bigoplus \mathcal{E}_i^\bullet(K)) = \bigoplus \text{Tot}(\mathcal{E}_i^\bullet(K))$$

by Modules on Sites, Lemma 18.29.2. The statement on homotopy colimits is a formal consequence of the fact that $R\Gamma$ is an exact functor of triangulated categories and the fact (just proved) that it commutes with direct sums. \square

Remark 46.20.4. Let X be a scheme. Because $X_{pro\text{-}\acute{e}tale}$ has enough weakly contractible objects for all K in $D(X_{pro\text{-}\acute{e}tale})$ we have $K = R\lim \tau_{\geq -n}K$ by Cohomology on Sites, Proposition 21.38.2. Since $R\Gamma$ commutes with $R\lim$ by Injectives, Lemma 19.13.6 we see that

$$R\Gamma(X, K) = R\lim R\Gamma(X, \tau_{\geq -n}K)$$

in $D(Ab)$. This will allow us to extend some results from bounded below complexes to all complexes.

46.21. Functoriality of the pro-étale site

Let $f : X \rightarrow Y$ be a morphism of schemes. The functor $Y_{pro\text{-}\acute{e}tale} \rightarrow X_{pro\text{-}\acute{e}tale}$, $V \mapsto X \times_Y V$ induces a morphism of sites $f_{pro\text{-}\acute{e}tale} : X_{pro\text{-}\acute{e}tale} \rightarrow Y_{pro\text{-}\acute{e}tale}$, see Sites, Proposition 7.15.6. In fact, we obtain a commutative diagram of morphisms of sites

$$\begin{array}{ccc} X_{pro\text{-}\acute{e}tale} & \xrightarrow{\epsilon} & X_{\acute{e}tale} \\ f_{pro\text{-}\acute{e}tale} \downarrow & & \downarrow f_{\acute{e}tale} \\ Y_{pro\text{-}\acute{e}tale} & \xrightarrow{\epsilon} & Y_{\acute{e}tale} \end{array}$$

where ϵ is as in Section 46.18. In particular we have $\epsilon^{-1}f_{\acute{e}tale}^{-1} = f_{pro\text{-}\acute{e}tale}^{-1}\epsilon^{-1}$. Here is the corresponding result for pushforward.

Lemma 46.21.1. *Let $f : X \rightarrow Y$ be a morphism of schemes.*
